Relief of pain is the goal of much of the physicians' striving and in his search for the ideal analgesic he has an enthusiastic ally in the organic chemist Rothschild[5] of Basle surveys some of the many newer pain-relievers and their chemical relationship with older remedies whose virtues and faults we know Among the fairly recent recruits is the carboxylic acid ethyl ester of 1-methyl-4-phenylpiperidine, officially named pethidine by the GMC a year ago and known on the continent as 'Dolantin' and in the United States as 'Demerol' Its structural formula invites comparison with the tropic acid series of antispasmodics Furthermore according to Schaumann[6] morphine should be considered a derivative of 4-phenylpiperidine rather than a phenanthrene The new drug therefore has reputable chemical kinsfolk Pethidine base is only very slightly soluble in water but the hydrochloride readily dissolves to produce a neutral solution

It would be a first-rate therapeutic event if it could be shown that while possessing at least some of the virtues the new arrival has none of the faults of its more famous relation The relief of pain by drugs is achieved in one of three ways the spasm of smooth muscle may be relaxed, the pain threshold may be raised, or the patient's attitude towards pain may be modified Experimentally pethidine has been found to act in the first two ways[7] It is a depressant to all forms of muscular tissue In its antagonism to the usual parasympathomimetic drugs it is weaker than atropine but it is more powerful than papaverine in counteracting the action of histamine on the intestine It has little effect on the pulse-rate or the pupil Pethidine therefore possesses properties which render it worthy of therapeutic consideration as an antispasmodic drug Secondly, and of still greater clinical value, it possesses a powerful analgesic action associated with stimulation rather than depression of the central nervous system Further it is said to be relatively non-toxic, lowering the blood-pressure and depressing the respiration only with large doses Unfortunately there is a wide gap between the pharmacological laboratory and the patient's bedside, and we are still in need of carefully controlled clinical investigation With analgesics more than any other type of remedy is it essential to beware of the vague impressions which often lead to a belief in non-existent virtues The few reports that are available are certainly encouraging for many types of visceral muscle-spasm, particularly renal and biliary colic and postoperative pain Pethidine has apparently been used with success in obstetrical practice, to alleviate pains when labour is of long duration and especially when delay is due to rigidity of the cervix[8], neither mother nor child was adversely affected It has relieved pain after injury or operation[9] and there are records of its value in the treatment of the severer types of neuralgia and such conditions as the tabetic crisis It is clearly worth a careful trial when relief of pain is desired without narcosis and in this connexion war-time casualties come specially to mind

The requirements of the ideal analgesic are rapidity and reliability of action, high margin of safety, freedom from objectionable secondary effects and lack of any tendency to habituation Since pethidine is non-irritant it can be administered by any of the parenteral routes as well as by mouth After an intravenous injection the analgesic effect appears within 15 and usually in less than 5 minutes and generally lasts for over 3 hours Undesirable side-effects, such as vasomotor disturbances, nausea and vomiting, have been reported but these were always relatively mild and of short duration HIMMELSBACH[10] observed that, when administration of the drug was continued for ten weeks, muscular tremors and twitches became evident at the end of the first week and persisted until the third day after withdrawal It may be concluded therefore that cumulative action is not well-marked As regards addiction, however, the reports are not so favourable VON BRUCKE[11] and KUCHER[12] suggest that pethidine may be habit-forming and the latter noted withdrawal symptoms HIMMELSBACH[10] has found that in morphine addicts pethidine partially satisfied the physical dependence established to morphine and that in subjects previously addicted to morphine physical dependence to pethidine resulted when this drug was given continuously for ten weeks Although the abstinence syndrome was milder after pethidine than after morphine there seems little doubt that pethidine carries the risk of addiction In Germany, indeed, steps have already been taken to prevent the indiscriminate use of this and similar preparations[13]

NATURAL HISTORY OF PARATYPHOID B

ALTHOUGH it is an enteric fever, paratyphoid B differs materially from the chief member of the group, and in a study of 40 outbreaks of the disease in Great Britain SAVAGE[1] points out how nearly the infecting organism behaves like a salmonella The association is close not only bacteriologically but also epidemiologically, and to a certain extent clinically The summer prevalence of the outbreaks —60% in May–July—approaches more closely to the seasonal distribution of salmonella food-poisoning than to the autumnal incidence of typhoid fever Paratyphoid and food-poisoning are conveyed in the same way by infected food In contrast with typhoid, water-borne outbreaks of paratyphoid fever are rare In the outbreak at Brixworth[2] the special feature was a heavy contamination of a very small water-supply Yet paratyphoid bacilli are readily recoverable from sewage and sewage effluents Experimentally WILSON and BLAIR[3] found the organism to be viable up to 21 days, the corresponding figure for typhoid bacilli being 38 days In 16 of the 40 outbreaks analysed by SAVAGE the vehicle of infection was cream He maintains that the number of organisms which must be ingested to initiate the disease is considerable, so that the organism must be able to multiply before it can infect Artificial cream, containing flour, vegetable oil, lecithin, powdered egg, sugar and water, is a particularly suitable medium in which multiplication can occur Synthetic cream is more likely to be infected in the bakery than in the factory, for the large-scale manufacture of cream involves less handling than the making of cream cakes and pastries[4] Next in importance to cream were milk (8 outbreaks) and ice-cream (2 outbreaks) Bread, cream cheese, tongue, trifle and water-cress were each responsible for an outbreak In this connexion it should be realised that food-borne infections do not necessarily cause explosive outbreaks

The incidence of paratyphoid B fever among the population at risk is low and intermittent, but a much greater number are infected than fall ill with the disease If these are taken into consideration the spread is found to be much more constant and extensive At Brixworth, for example, 34 people were at risk but only 4 contracted the disease, yet 21 others were infected, some of whom could be classed as mild ambulatory cases These, if missed —as they may readily be—are indubitably a potent source of infection While admitting the occurrence of chronic carriers, SAVAGE regards them as much less important epidemiologically than mild missed cases The case-fatality in these outbreaks was 1 76%, compared with 1 5% for acute food-poisoning due to living salmonella strains It is well recognised that paratyphoid fever, particularly in children, may produce the gastro-intestinal symptoms—diarrhœa, vomiting and acute abdominal pains—characteristic of acute food-poisoning These may be the only symptoms but more commonly they are followed, either immediately or after an interval, by typical enteric symptoms In the Consett outbreak described by WARREN[5] 76% of the cases started with gastro-intestinal symptoms and in a fifth of these they were the only symptoms. Such figures are exceptional but they add point to SAVAGE's views.

Many of the older writings on the disease are invalidated by their failure to distinguish between *Bacterium paratyphosum B* and other salmonellas, particularly *Bact typhi murium* (*B aertrycke*). SAVAGE, emphasising the relationship, postulates a recent common origin for these organisms. In its evolution the paratyphoid bacillus has acquired some of the invasiveness of the typhoid bacillus while retaining some of the intestinal irritant properties of the salmonellæ. This point is further elaborated in SAVAGE's discussion of the variable incubation period of the disease. During incubation the organisms multiply in the mesenteric lymph-nodes, the liver and the spleen. With the onset of the disease a bacteræmia occurs. Positive blood-cultures can be obtained in 90% of cases in the first week, 75% in the second week and 60% in the third week. The recovery of the organism from the stools in greatest numbers during the second week is not due to their multiplication in the bowel but to their being excreted partly in the bile. On the other hand, food-poisoning is a purely enteral infection and invasion of the blood, except as a terminal event, is rare. SAVAGE finds here an explanation of the relatively long incubation period of the enteric fevers and contrasts it with the short period for food-poisoning and for the gastro-intestinal symptoms of paratyphoid fever. This speculation is worthy of further investigation: if there is any substance in it, cases of paratyphoid fever without enteric symptoms should have no bacteræmia. KAUFFMANN[6] regards the enteric and gastro-intestinal forms of the disease as due to different strains of the organism. The classical bacillus does not ferment *d*-tartrate and produces a mucous wall around agar colonies, whereas strains causing gastro-enteritis ferment *d*-tartrate and do not produce the mucous wall. This appears to be a fundamentally different view from that of SAVAGE who regards the classical paratyphoid bacillus as a recent variant from other salmonellæ. Except for its occasional invasion of dogs it has become almost an obligatory human parasite, albeit one which does not readily infect man. So impressed is SAVAGE with the view that *Bact paratyphosum B* is a true salmonella that he attributes its epidemiological behaviour to this relationship.

Annotations

COMFREY, MAGGOTS AND UREA

IN 1912 Dr C J Macalister, stimulated by the story[1] of the disappearance of a nasal sarcoma under poultices of comfrey root, set out to investigate the properties of the common comfrey of our ditches and dunghills. This comely but bristly herb, rightly eschewed by cattle, had been held in high esteem in rural England since Saxon times as a specific for wound healing.[2] Macalister[3] had extracts of the root analysed by Mr A W Titherley, D Sc, who found that they contained a relatively high proportion of allantoin. He used both crude extracts of the root and solutions of pure allantoin to treat a series of chronic ulcers that had failed to respond to other forms of therapy, and was convinced of their efficacy. He was cautious in drawing conclusions, too. "One is rather apt," he says, "when experimenting with a substance in this way, to allow optimism to exaggerate the resultant benefits, and it is an advantage to get others to form an independent judgment concerning them from their own observations"[4]—words which might be taken to heart at the present day. Nevertheless he was convinced that he had found a cell proliferant, if only for the reason that gr 6 of allantoin taken in divided doses over a period of six hours would run his own white cells from 6000 up to 15,000 or more per c mm. William Bramwell,[5] also of Liverpool, suggested that comfrey dressings succeeded because they set hard and adhered closely to the skin. Allantoin had been known since 1821, when it was found, not in sausages as the classically minded might imagine, but in the allantoic fluid of cows. It occurs in many plants and is a normal constituent of the urine of all mammals, where it is an end-product of purine metabolism. Man and the Dalmatian coach-hound share the distinction of having none in the urine except what they have eaten ready made. It is glyoxyldiureide, $C_4H_6O_3N_4$. Allantoin appeared again in surgical writings after it had been shown to be present in the excretions of maggots,[6] for military surgeons have acknowledged the benefits of maggot infestation in severe wounds for as far back as records extend. Further examination of the action of allantoin suggested that its action in accelerating wound healing arose from its ability to break down and form urea.[7] Urea had earlier been shown to assist the healing of infected wounds and ulcers, though how it does so remains doubtful. W Ramsden demonstrated in 1902 that proteins dissolve in strong solutions of urea, and that weaker solutions hasten the action of proteolytic enzymes; the clue may lie there. More recent studies of the action of allantoin on healing processes have not been encouraging; Chu,[8] in fact, found that far from accelerating the growth of epithelial cells solutions of allantoin retarded their multiplication in vitro, and the Council on Pharmacy and Chemistry in the USA thought there was insufficient evidence in 1938 to accept commercial preparations of allantoin as healing agents. Lately allantoin has been mixed with sulphanilamide for application to raw surfaces, but the efficacy of this traditional remedy has yet to be placed on a firm basis.

PROGNOSIS AFTER PERFORATION

THERE is a widespread impression that if a patient recovers after operation for a perforated peptic ulcer he has a good prospect of a lasting cure of the ulcer. Writing in 1918, D C Balfour of the Mayo Clinic referred to the "clinical fact . . . now generally recognised that perforation of a gastric ulcer is quite likely to be followed not only by the cure of the ulcer but by the cure of the patient." This optimistic view moreover is based on the assumption that nothing more than simple closure of the perforation has been done. No explanation seems to have been offered, but it might be supposed that a patient who has once perforated will thereafter be more likely to remember his physician's advice and take care with his diet and ways of life. In this way an acute catastrophe in an ulcer may prove a lasting blessing, but its moral effect will be lost if the popular error is allowed to persist that once an ulcer has perforated there will be no more trouble. For this reason, if for no other, careful studies of the after history of perforation cases are useful Lately Harrison and Cooper[1] have analysed 57 cases Of these, 16 died in hospital, the fatality rising from 13% in those operated on within ten hours of perforation to 46% in those in whom operation was delayed for up to 24 hours Of the 41 patients who left hospital all were followed up after periods ranging from one to twelve years, and it was found that only 7 (17%) had remained free from symptoms Of the remainder, 2 had died and most of the other 32 had had only a short period, averaging 1 8 years, free from symptoms after leaving hospital, the one who had the longest asymptomatic period had this abruptly terminated by a second perforation Very few of the patients had strictly followed any course of medical treatment after their operation These figures, besides exploding a dangerous misapprehension, serve to emphasise the fact that the treatment of chronic peptic ulcer can never be surgical alone, and that to extract any good from the evil of perforation requires not only early diagnosis and skilled surgery but a warning to the patient that this disaster is but an incident in a condition which requires care throughout life, suture after perforation is not a final cure for a "simple ulcer," but the saving of a life from an acute complication in a chronic constitutional condition

EPIDIDYMITIS

GONORRHŒA is the commonest cause of acute epididymitis and the chronic form is most often tuberculous Occasionally, however, tuberculous involvement of the epididymis may manifest itself in an acute form and cause confusion in diagnosis The differential points of value are summarised in the *Army Medical Directorate Bulletin* for July (p 6) In tuberculous cases the onset is more gradual and pain and tenderness are less severe, the epididymis and vas may present nodules which become adherent to the scrotum and later break down to form sinuses In addition, there may be evidence of involvement of other parts of the genito-urinary tract and it may be possible to demonstrate tubercle bacilli in the urine In gonococcal cases the epididymis is smooth, very tender and uniformly enlarged, the vas is not nodular and the scrotum is not adherent Although urethral discharge usually abates abruptly with the onset of the epididymitis, the urine often still contains shreds The response to adequate chemotherapy is another point of value—gonococcal epididymitis rapidly subsides while tuberculous cases fail to respond Since both types of case may be sent to the VD wards in the first place, the venereologist must keep the possibility of tuberculous epididymitis in mind if he is to avoid delay in starting appropriate treatment

PULMONARY EMBOLISM BY AMNIOTIC FLUID

IN the past few years much attention has been paid to fat-embolism as a cause of shock symptoms in patients with fractures and severe trauma, such as are caused by motor accidents and air-raids An analogous condition has been shown by Steiner and Lushbaugh[2] to play an important part in the pathology of "obstetric shock" In 9 patients who died during labour or within eight hours after delivery they found multiple embolism of the small branches of the pulmonary arteries The material forming the emboli appeared to be particles of fœtal products which had been floating in the amniotic fluid during the labour Mucus from meconium, and squames, vernix caseosa and lanugo from the fœtal skin, were all recognised as constituents of the emboli In addition there was often heavy infiltration of the emboli with leucocytes, even within an hour of the first onset of symptoms The mucinous emboli were long and were usually impacted in arteries about 1 mm in diameter, the embolism by squames and vernix was usually in small arterioles and capillaries The manner in which the liquor amnii gains access to the uterine veins is not clear In one of the cases there was rupture of the uterus, and in another case cæsarean section had been performed through the placental site In the remaining cases the uterus was intact, it is presumed that a tear had occurred through the membranes and into the uterine veins, but such a tear has not actually been demonstrated Clinically the usual course in these patients had been as follows The patient was a rather old multipara with a large fœtus past term, possibly dead in utero, and with meconium in the amniotic fluid The labour pains were strong and sometimes tetanic During labour or very soon after delivery there was a sudden onset of shock with chill and restlessness, dyspnœa and cyanosis, and sometimes vomiting The syndrome presented similarities with an anaphylactic reaction to foreign protein Sometimes there was œdema of the lungs, and sometimes there was some post-partum atony of the uterus with moderate hæmorrhage Death usually occurred in from 1 to 11 hours after the first onset of these shock symptoms These 9 cases are all fatal ones, *for at present direct evidence on the matter can only be* obtained at autopsy Nevertheless it seems probable that some non fatal cases of obstetric shock are due to this cause Steiner and Lushbaugh examined the lungs of 34 women who died of other conditions during late pregnancy or the puerperium, these controls were all negative Subsequently, however, they examined the lungs of a woman who had rupture of the uterus and severe shock at the time of delivery but survived until the seventh day of the puerperium In this case there were pulmonary emboli in a healing stage, the mucinous emboli being infiltrated by macrophages and the emboli of particulate matter showing a well-marked foreign body giant cell reaction Further evidence was obtained by the intravenous injection of human amniotic fluid and meconium into dogs and rabbits The immediate clinical and pathological effects were much the same as in human patients A satisfactory study of the later pathological changes in animals was unfortunately prevented by bacterial contamination of the injected material It is rather astonishing that so striking a lesion as this should have been overlooked by all previous workers on obstetric shock

EYE SIGNS IN SUBARACHNOID HÆMORRHAGE

BEFORE the introduction of lumbar puncture cases of subarachnoid hæmorrhage from an aneurysm of the circle of Willis were classed as "apoplexy" and no further diagnosis was sought Lumbar puncture reveals a blood-stained cerebrospinal fluid in some of these patients, and if this is coupled with a cranial nerve palsy and rigidity of the neck the diagnosis is not often in doubt The ophthalmoscope is a useful accessory to diagnosis, for examination of the retina will show hæmorrhages into the eye in most cases Post mortem examination of the orbit often reveals that the optic nerve is surrounded by blood, due, it was supposed, to direct extension from the cranial cavity, the blood having passed through the optic foramen and down the prolongation of the cranial membranes which surrounds the optic nerve It was also thought that the blood inside the eye came there by direct extension from the subarachnoid cul de sac behind the globe Riddoch and Goulden,[1] however, after a critical examination of five patients suffering from this disease, concluded that while the blood could track through the optic foramen and down the sheath of the nerve it could not pass from the sheath of the nerve into the eye, and that where intraocular hæmorrhage occurred, it did so by the same mechanism as operates in papillœdema—the central retinal vein is compressed as it passes through the subarachnoid space some 10–12 mm behind the eye, and by this means venous stasis inside the eye is produced There seems much to support this argument for it is clear that peripheral retinal hæmorrhages—which sometimes occur—could not come from direct extension from the nerve sheath Ballantyne,[2] in five fatal cases of subarachnoid hæmorrhage, found that there were often scattered hæmorrhages throughout the orbit, in the fat and around the ciliary ganglion They seemed to have no connexion with the subarachnoid hæmorrhage and Ballantyne submits that the old story of direct extension from the cranium will not do He concludes that the changes he found in the orbit can only be accounted for by some mechanism which produces venous stasis in the whole orbit, and suggests that we have such a mechanism in the sudden and forcible increase in intracranial pressure produced by the hæmorrhage, which in turn causes pressure on the venous sinuses inside the cranium One would have thought, however, that the extensive alternative venous drainage of the orbit by way of the facial and deep facial veins would have prevented venous stasis in the orbit Dupuy-Dutemps[3] quotes some experiments by Sicard in which grains of chinese ink injected into the subarachnoid space of living animals found their way through the dural sheath and into the cellular tissues This seems to offer an alternative explanation to the findings in the orbit in these patients

GLYCOLS IN AIR-DISINFECTION

THE bactericidal action of both mists and vapours has been investigated in relation to the control of cross-infection in respiratory diseases, and it is generally agreed that vapours are effective provided they are sufficiently concentrated But since Bechhold[4] asserted that weight for weight phenolic bactericides were much more efficacious as mists than as vapours attention has been mainly turned to the production of stable and durable mists Robertson and his colleagues[5] of Chicago have found that propylene glycol, much used by previous workers as a solvent for germicides, is itself germicidal, and is more effective as a vapour than when an equal quantity is dispersed in droplets 1μ to 2μ in diameter as an aerosol At a temperature of 20° C, they say, 1 g per 1 4 cubic metres of air saturates the atmosphere, though less than half this amount, evaporated from Petri dishes overnight, killed the various organisms tested almost at once They demonstrated a very high lethal effect of the glycol when it was dispersed as an aerosol in a concentration of 1 g per 2 cubic metres of air, or when dispersed as a vapour in about a quarter of that concentration Actually vapours are presumably concerned in both cases, for small particles of most of the glycols evaporate completely in a few seconds or even a fraction of a second Some of the other glycols acted as bactericides in the same way Propylene glycol, however, has the advantage of being much better tolerated by animals Cases of glycol poisoning in man, even from inhalation of the vapours, have been reported, but not, apparently, from propylene glycol On the other hand, mice are apparently unaffected by living for weeks in an atmosphere supersaturated with ethylene glycol, although there is a limit, especially in females, to the amount they can take by mouth Stokes and Henle[6] of Philadelphia have found ultraviolet irradiation and vaporisation of propylene glycol highly and about equally effective in preventing air-borne infection of mice with the virus of influenza A The ultraviolet light was projected as a "curtain" in front of each cubicle and also in the upper part of the ward above the cubicles The glycol was vaporised from a hot plate placed in front of an electric fan near one of the ward windows so as to give a concentration of 1 in 2–4 million They also quote an unpublished controlled experiment by T N Harris in which a concentration of one part of propylene glycol vapour in 30–40 million parts of air was strikingly successful in protecting children in a convalescent home from respiratory infection

METABOLISM OF PLASMA PROTEINS

THOUGH easily accessible for study or assay, the plasma proteins have always been rather neglected by physiologists Starling early established that one of their functions was the exertion of colloidal osmotic pressure in the circulating medium This function is now well understood and the part it plays in the formation of lymph and of various types of œdema has been thoroughly explored For many years Whipple[1] and his colleagues have been studying in dogs the formation and the wider functions of the circulating proteins One aspect of this work has been the intermittent removal of large amounts of plasma proteins to discover what type of diet will cause the most complete and rapid resynthesis This approach has led to the conclusion that some dietary proteins are much more efficacious than others and that proteins which favour hæmoglobin formation are not necessarily those which favour plasma protein production, as might be expected, the proteins of serum itself are the most effective that can be taken by mouth These views have not gone unchallenged however, Melnick, Cowgill and Burack[2] found that serum proteins, casein and lactalbumin each give an equally good synthesis of plasma proteins Further experiments in Whipple's laboratory have shown that dogs which have been depleted of plasma proteins for some time are abnormally susceptible to infections of many kinds and to poisoning with chloroform and organic arsenicals The susceptibility can be removed in a day or two by a high protein diet, or immediately if considerable amounts of plasma protein are given intravenously The amino acid methionine has the same effect These observations may have considerable therapeutic significance Some of the experimental results of these workers seem a little revolutionary to the conventional physiologists Thus they have shown that dogs may be maintained in nitrogen equilibrium for weeks solely by the intravenous injection of plasma protein This suggests either that these proteins must be broken down in the liver and their amino acids redistributed to other tissues according to their needs, or that the plasma proteins themselves must enter the cells of the body, there to be transformed into the proteins characteristic of the cell Whipple favours the second hypothesis It would be helpful to see this work confirmed on another species before the results are accepted as applying to man

SPEED AND DELAYED FRACTURE UNION

THE orthopæd has lately been heaping abuse on his own methods of treating the fractured tibia Excessive traction, the pin, the non padded cast, long immobilisation have all been blamed, and it has been urged that it would be better to make certain by earlier and more frequent operation J P Campbell at the Nottingham meeting of the Orthopædic Association says Not at all, lift up your hearts, you are at least as good as your forefathers at the treatment of these fractures The "modern" delayed union of the tibia, he maintains, is due to the increased severity of the injury, in the simple fracture union takes no longer than of old In an analysis of 54 tibial fractures at the junction of middle and lower thirds, he divides the cases into slight—those arising in football, boxing or jumping, and severe—those that followed motor-cycle, gunshot wounds or other explosions The average period of disability for the 10 slight cases was 16 weeks and for the 44 severe cases 28 weeks The period of disability for the slight injury probably compares favourably with that with treatment by the older methods Radiographic evidence was in these cases the indication for removal of the plaster and the start of weight bearing Campbell found that plaster immobilisation itself led to weakness, pain or limitation of movement in joints, which were not previously involved As a rule, the convalescing period was about twice the period in plaster, so that the longer the plaster immobilisation the longer was the subsequent convalescence, and this was despite regular exercises for toes and knee from the outset and the use of a walking foot plate after 4–6 weeks Campbell has therefore started removing the plaster on the first indication of clinical union, which is several weeks before radiographic union The limb is then supported on a plaster back splint, and non-weight-bearing exercises are begun, weight-bearing being started when X rays show union In 25 of the 44 severe cases the injury was due to a motor cycle accident and Campbell recommends a special metal shin guard for the motor cyclist Rowley Bristow in the discussion said the opinions of a large number of dirt-track riders and other motor cyclists have been taken on shin-guards, and the Army has decided that the only effective protection is a guard on the motor-cycle itself Many motor-cycles have already been thus fitted He also stressed the importance of care in handling these fractures, reduction by the onlooker often results in the enclosure of a large mass of dirt between the bone ends

LCC AND MEDICAL STUDY

THE LCC are putting some hard thinking into the preparation of their evidence for the Interdepartmental Committee on Medical Schools We have already described their reactions as a local education authority (*Lancet*, Oct 10, p 444), and now they have spoken their mind as the major health authority for London, as the largest civilian employer of medical staff in the country, and as the administrator of hospital and public health services which offer facilities for a complete medical training The council therefore begin by suggesting to the interdepartmental committee that not only should these facilities be used to increase available resources for the teaching of medicine but that an undergraduate medical school should be set up based on one of their larger general hospitals, and making use of special hospital and institutes as required They feel that there is room for more integration in the teaching which now obtains between the voluntary and municipal hospitals if continuity of the curriculum is to be ensured and gaps avoided They suggest that an advisory body, similar to that which now makes appointments to university chairs, should be established for each combination of linked municipal and voluntary hospitals Representatives of both kinds of hospitals and of the university would sit on these bodies Junior clinical appointments would be interchangeable between the linked hospitals and if it is decided that a medical student must after qualification and before registration hold a house-appointment the council will adjust its staffing arrangements After the war they would be prepared to extend the arrangements for medical students to live in at their hospitals to receive *instructions in* such subjects as obstetrics and fevers The council believe that psychological medicine must find a more important place in the training of the doctor of the future, and that organised instruction supplemented by visits to institutions should introduce him to the public health and welfare services Every student should attend confinements in the home as part of his training The council think that there should be better coordination of London postgraduate facilities and suggest that here the British Postgraduate Medical School, with an office in the academic centre of London, has an important part to play in advising graduates where their needs could best be met

ACCIDENTS AND ACCIDENTS

THE *National Insurance Gazette* of Sept 24 suggested that approved societies might help in distinguishing accident prone workers in order that this small minority might be removed from dangerous occupations. The societies should certainly have among their records many relevant data, but any analysis of them for such a purpose would have to be carefully considered Those workers named as being accident prone by the societies might be penalised if they were debarred from a dangerous occupation without being provided with a safer post carrying comparable rewards, and there might well be grounds for legal complaint against the body which had so stigmatised them Nor are the records of approved societies necessarily complete enough to allow of fair judgment They usually record only such relatively serious accidents as keep a man from work for more than three days, but take no note of minor accidents Yet in deciding whether or not a worker is accident prone careful records must be kept of all accidents, even the most trivial As Vernon has pointed out,[1] for all we know the trivial accident may be as reliable an index to proneness as the serious one Even the fact that a worker has had several minor or major accidents may not mean that he is accident prone his job may be intrinsically dangerous, the machines insufficiently guarded, or the lighting bad, and others doing the same job may sustain an equal number of accidents Some accidents, as we all know, are the fault of other people If he was one of a group of workers doing the same job under comparable conditions, and he had many more accidents than his mates, a man might perhaps fairly be called accident prone Even then it would be necessary to ensure that he had no physical disability—like defective eyesight—the correction of which might do away with the proneness Real accident-proneness is presumably psychological, not physical, and the diagnosis can perhaps best be made in the factory, and individually, by the works doctor—possibly helped by a psychologist Physical causes of incoordination must of course be excluded If a worker really is accident prone, he can usually be transferred tactfully to some less dangerous job without having a label attached to him

DR **ROBERT J ROWLETTE**, PRCPI, has been elected president of the Royal Academy of Medicine in Ireland

Prof **HARRY PLATT** will deliver the Robert Jones lecture at the Royal College of Surgeons on Wednesday, Nov 4, at 3 15 PM He will speak on congenital dislocation of the hip joint At the same hour on Thursday, Nov 12, Mr **L R BRAITHWAITE** will give a Bradshaw lecture on the rôle of bile *in duodenal* regurgitation

LABELLING OF CASUALTIES—Where necessary casualties are labelled by first aid parties (light rescue parties in London civil defence region) at an incident Tie on labels, with a symbol written on them, are used and, if possible, the forehead of the patient is also marked with the same symbol in indelible pencil The symbols used for *marking and their interpretation* are as follows —

X—Requires priority of removal from the incident and of examination when reaching hospital This is used mainly, but not exclusively, for wounds of the chest and abdomen and for internal hæmorrhage

T—A tourniquet has been applied The time of application of the tourniquet and subsequent releases should also be indicated on the label

H—Severe hæmorrhage has occurred

M—Morphine has been given The time of administration and dose should be written on the label

C—Contaminated by persistent gas

XX—Poisoned by phosgene gas or suspected of having been so poisoned

Public Health

Stubborn Good Health

THE summary report[1] of the Ministry of Health reveals the state of the country's health in 1941–42, "stubborn good health" Mr Brown calls it—there were no sensational events, and but a few outbreaks of disease on a small scale Epidemic prevalence of cerebrospinal fever continued but decreased from 12,711 to 11,077 notifications and its mortality from 62 to 52 per million population The case fatality of recognised cases remained at about 20 per cent Diphtheria increased from 46,281 cases with 2180 deaths to 50,797 cases with 2641 deaths despite the great increase in inoculation The number of children immunised can hardly be less than 3,000,000, about a third of the under-15 population, but "it is generally recognised" the report states, "that no substantial improvement in incidence or death-rate can be expected until at least three-quarters of the child population of the country have been immunised" This statement needs careful reading if it is not to be misunderstood There was no typhus and only two cases of native malaria, though outbreaks of both had been anticipated Under "droplet infection" we are told that apart from other inconveniences of droplet-spread diseases they cause an enormous interference with the war effort "Unfortunately the supply position did not allow the sale of handkerchiefs free of clothing coupons, though this might have been a great help to the campaign"—sounds rather a lame excuse There has been more venereal disease especially primary syphilis, since the war started, judging by cases which attend clinics or occur in the Services, new syphilitic infections have gone up by 70 5% But as notification is not compulsory the position is uncertain and it should not be forgotten that just before the war the incidence of syphilis had fallen to a level never known before At the end of 1941 it was about the same as at the end of 1932 Gonorrhœa reckoned to be 8–9 times as frequent as syphilis, has increased less in the war period The report speaks of the value to the public of the Pharmacy and Medicines Act 1941 which prohibited the advertisement of articles for the treatment of diseases, such as Bright's disease and diabetes, or for procuring abortion, and required disclosure of the composition of any substance recommended as a medicine But although no preparation may be sold as a cure for Bright's disease or tuberculosis, it is still legal to sell kidney medicine or lung tonic which to those who waste their money on them mean the same things, and anybody can sell female pills to remove irregularities The number of women who received antenatal attention, either at clinics or through arrangements with practitioners, was 74 5% of the total number of births, 97% of registered live births were visited by health visitors, and 68% of children born attended welfare clinics Much of the report is devoted to war-time measures and there is a chapter, austerely non-committal, on hospital policy

The black spot is tuberculosis, which in 1941 appeared to be repeating the unfavourable trends noticed in the last war Fatal tuberculosis increased 12% for both sexes in England and Wales, and 15% for males and 25% for females in Scotland, over the 1938 rates The greatest increases were in fatal meningitis, which were 34% in males and 38% in females in England and Wales, and 37% in males and 60% in females in Scotland In the last war there was no increase in meningitis Though fatalities from tuberculous meningitis in England and Wales increased from 1684 in 1938 to 2367 in 1941, even this is less than half the number for any year in the last war Fatal tuberculosis in children under 5 years and in those aged 5–10 has increased greatly since the war started From 1914 to 1916 there was a *decrease* of deaths from tuberculosis in under fives of 6% in males and 2% in females From 1939 to 1941 there was an *increase* of 46% in males and 51% in females In 1938 notifications of respiratory tuberculosis were 43 205 and deaths 21,930, in 1941, the notifications were 46,256 and deaths 23,633 Of other tuberculosis the 1938 figures were 14,888 notifications with 4246 deaths, and those for 1941 (subject to revision) 13,720 notifications and 5037 deaths In Scotland all tuberculosis increased from 7176 notifications with 3526 deaths in 1939 to 8302 notifications with 4173 deaths in 1941 Local reports on the position of tuberculosis must be read with caution, for often an increase is due not to new cases but to transfers of existing cases from other areas But the figures for the whole country show a real rise in incidence

Shelter Health

Finsbury suffered severely from bombardment in the first half of last year and on the whole has been as much disturbed by war as any part of the country, yet its health record for 1941 was good Dr C O S Blyth Brooke in his brief annual report remarks "though the community was sleeping in air-raid shelters to a very large extent there was a marked absence of epidemic disease," and Dr A G Thompson in his report of *Lambeth* which suffered as badly as Finsbury, has much the same to say Indeed, from all areas comes the same story—in spite of everything being favourable for the spread of infection, the infectious diseases in Britain remained at the lowest level in our history

The almost complete absence of typhoid is the most remarkable epidemiological feature of 1941–42, for in many of the great towns air-raids caused great destruction of water-works and fouling of public supplies was inevitable Yet no epidemics are reported In July there were only 23 notifications of typhoid and 39 of paratyphoid in England and Wales against 1056 for the two in July, 1941 On the other hand, there were 696 notifications of dysentery against 360 in July, 1941, but most of the dysenteries were of the Sonne type which is not dangerous Again shelter-life should be conducive to droplet-infection, but if droplet dissemination was more concentrated and widespread than in peace-time, no increase of disease from it has occurred so far Rationing, anxiety, exposure and shifting cannot be favourable for the well-being of the population, yet the public health was never better Maternal mortality maintained the low level of little more than 2 per 1000 in spite of the difficulties of confinements Before the days of the Committee on Maternal Mortality we looked at 4 per 1000 as a satisfactory death-rate This committee settled that half of the maternal deaths which were occurring were practically preventable, a further quarter theoretically preventable and the remainder inevitable in the existing state of knowledge We therefore now look to 2 per 1000 as a satisfactory rate and it is surprising how near we have got to it

Another pleasant surprise is the rarity of food-poisonings especially of those due to salmonella Meat rationing may have had something to do with this, for many of the British delicatessen generally cooked and bought in conditions in which they could only escape infection by accident have disappeared In the early days of the war several outbreaks of trichinosis from eating raw sausage-meat, and of paratyphoid spread by artificial cream were recorded, but we have had little of them since the middle of 1941

From the School Reports

The death of a school child is a domestic tragedy, a national misfortune and, what concerns us most, usually a medical failure, for most deaths between 5 and 15 are due to diseases which in theory are entirely preventable and in practice generally curable Dr Stephen Rowland in his school medical report for *Northampton* borough gives a table of the causes of death among children in this age-group during the past 15 years There were 299 of these deaths, 1 7% of deaths at all ages Excluding 66 due to "other conditions" not specified, but which include all unavoidable fatalities, of the remaining 233 there were 35 due to violence, the rest, with one possible exception, were due to infections Violence with 11 7 of all the deaths comes third on the list In 1927–36 it caused an average of 2 3 deaths per year, in 1937–41 an average of 2 4, but in 1940 there were 4 and 1941 there were 6 such deaths Tuberculosis stands first with 17 1% of the total, but whereas in the first two quinquennia it caused an average annual of 3 8 deaths, in the last quinquennium its average was 2 6 Diphtheria stands second with 39 deaths, or 13 0% of the total, and from an average of 2 3 deaths per annum in 1927–36 it rose to 3 2 in 1937–41 Respiratory infections caused 33 deaths, appendicitis 10, measles and whooping-cough 8, and scarlet fever 2. Meningitis, presumably forms other than tuberculous, caused 9 deaths. Heart disease, rheumatic fever and nephritis together caused 46 deaths or 15.4% of the total. Some of the heart cases may have been congenital, but there is a growing suspicion that the nephritis of children is sometimes rheumatic in causation. The deaths are few, but their distribution is comparable with that in other areas. The zymotic death-rate for the whole population of Northampton in 1941 was 0.10 per 1000 made up of 11 deaths, 1 due to measles, 2 to whooping-cough, and 8 to diphtheria. There were 86 notifications of puerperal pyrexia (about half of them were non-residents) giving an attack-rate of 49 per 1000 births. Only 1 death was due to puerperal infection. In the old days of pueperal fever notification there were generally more deaths than notifications; nowadays the fatality of puerperal pyrexia depends upon the completeness of notification, but we have noticed that districts reporting a high incidence of pyrexia not only show a low case-fatality, but also a low infection mortality-rate per 1000 births.

---

[1] Cmd 6340 HMSO Pp 35 9d

The death-rate in *Bootle* rose from 12.4 in 1939 to 17.3 in 1940 and to 23.3 in 1941 but Dr. E. T. H. Wood warns us against interpreting this as a sign of deterioration of the health of the borough, for the composition of the population has been much altered by evacuation. There were, however, some bad spots. Infantile mortality was 108; whooping-cough caused 24 deaths and diphtheria 15. The "young child mortality," or deaths between one and five years of age, was 66 deaths, of which 17 were ascribed to whooping-cough, 13 to bronchitis and pneumonia, 13 to violence, 6 to diphtheria and 5 to tuberculosis. Of the infant deaths only 22% occurred during the first week, but 35% in the first month. It is clear that in Bootle in 1941 the dominant destroyer of the young was whooping-cough. Only 443 notifications of whooping-cough were received so the fatality based on deaths directly ascribed to the disease and the notifications was over 5%. Pertussis falls heaviest on infants, and in Bootle, of 122 deaths of infants under a year old, 7 were ascribed to whooping-cough; but 31 to bronchitis and pneumonia, 10 to convulsions and 11 to enteritis, and it is likely that a high proportion of these 52 deaths were really caused by pertussis. The infantile mortality was higher in legitimate than in illegitimate children (108 to 98). The numbers are too small to give significant results, but they suggest some lethal influence falling on all infants alike.

In *Ilford* the infantile mortality-rate was 40.9. Of the 67 deaths which made up this rate, 7 were ascribed to whooping-cough, 16 to bronchitis and pneumonia, and 5 to diarrhœa. In the whole population 1161 cases of whooping-cough were notified with 9 deaths, giving a fatality, based on deaths directly ascribed to whooping-cough and number of notifications, of less than 1%.

In reading the vital statistics of 1941 of the health of infancy and childhood whooping-cough is the outstanding factor which causes local and topical departures from normal. This disease has been notifiable since the war, but no disease can be notified unless it is diagnosed and, generally speaking, whooping-cough cannot be diagnosed in the absence of the whoop. Infants with pertussis rarely whoop and many of them die from the disease before the suspicion of whooping-cough is aroused—indeed many are not seen by doctors until moribund from pneumonia or enteritis. In older children, whooping-cough is readily recognised but is of low fatality, so in epidemics of whooping-cough the "official" fatality is highest where notifications are fewest.

Infectious Disease in England and Wales

WEEK ENDED OCT. 10

Notifications.—The following cases of infectious disease were notified during the week: smallpox, 0; scarlet fever, 2613; whooping-cough, 972; diphtheria, 991; paratyphoid, 11; typhoid, 6; measles (excluding rubella), 4650; pneumonia (primary or influenzal), 511; puerperal pyrexia, 192; cerebrospinal fever, 57; poliomyelitis, 23; polio-encephalitis, 2; encephalitis lethargica, 3; dysentery, 209; ophthalmia neonatorum, 104. No case of cholera, plague or typhus fever was notified during the week.

Deaths.—In 126 great towns there were 1 (0) deaths from enteric fever, 1 (0) from scarlet fever, 8 (0) from measles, 6 (3) from whooping-cough, 12 (0) from diphtheria, 57 (8) from diarrhœa and enteritis under two years, and 12 (0) from influenza. The figures in parentheses are those for London itself.

Coventry reported the fatal case of an enteric fever. There were 7 deaths from diarrhœa at Birmingham.

The number of stillbirths notified during the week was 229 (corresponding to a rate of 35 per thousand total births), including 25 in London.

In England Now

A Running Commentary by Peripatetic Correspondents

I WAS ashamed when one of my fellow students rebuked your correspondent for saying that we were illiterate. Of course we are. And although it is true that some textbooks tend to foster illiteracy ("we were fortunate in persuading Professor X to undertake the revision of the *Digestive System*"—Gray, 28th edition; "curves, where absolutely necessary, should not be less than ten times the cross-sectional diameter of the sewer"—Frazer and Stallybrass), yet they are not the real cause of the trouble. The real cause, surely, is that if we open a serious book we feel that it has to be a medical book. In spite of Osler, the literary student is a rarity; and the literary doctor not much less rare. Too often the ones we can point to today—Maugham, Cronin, Brett Young—have not attained that distinction in medicine to which we all, when young, aspire. One wonders even whether Sir Thomas Browne would have known his Osler as well as Osler knew his Sir Thomas Browne; whether there is not some impossibility in the attainment of two such divers skills as the re-ordering of words and bodies. And in any case one knows darn well that there are quite enough books to be read without going to the library for more. In the five years of his study, it is hopeless to ask the student to have a clear conscience when his reading strays far afield. The Americans have tried to solve the problem by four years' compulsory study at a university before medicine proper begins. And even then—

* * *

The popular press and the less humorous professional humorists no longer seek to amuse us by sallies at *ersatz* productions. Not long ago a reference to a German suit of clothes dissolving in the rain was always good for a laugh, although a little thought would have disclosed our own dependence on similar manufacturing processes. The invention and application of substitutes has, in fact, been a major industrial process for years to an extent scarcely believable by the man in the street. Many of the fabrics used in female clothing (except of the most expensive kind) are ersatz, derived from wood pulp. "Silk" stockings, "poplins" for underclothes and dresses, and heavier fabrics for suits and dresses may all begin as logs of wood. Other processes utilise sea-weed and various industrial by-products as the starting-point.

I was recently taken through a mill where some of these fabrics are woven. The mill was built originally for cotton weaving, but it closed down in the cotton slump after the last war. The present owners specialise in the "fancy" rayon trade. The raw material depends on no vicissitude of weather in the Americas or India, no eccentricity of Customs legislation or freightage facilities. It is made in this country largely by the two firms controlling the major patents—a few small firms still manage to survive in competition, using other methods of production. Although on a very large scale, everything is, as it were, custom built. The fibre can be spun to any required thickness or weight by varying the composition and consistency of the gel and the size of jet through which it is extruded. The weaver merely specifies his requirements. He has already worked out his pattern and decided on the weight and finish, and is able on one and the same machine to turn out the thinnest, most silk-like "poplin" or a rough, heavy "tweed." The actual weaving does not differ from the weaving of natural cotton, silk or wool except in detail. The old bogies of temperature and humidity are no longer matters of chance. Air-conditioning achieves the optimum of both and climate no longer controls the site of a mill.

Science is plentifully on show in this mill. The initial process of transferring the fibre from the reels on which it is originally wound when produced to reels the correct shape and size for the subsequent machines is itself a bewildering achievement. It seems absurd that half a dozen girls and women can tend and control these hundreds of bobbins dazzlingly spinning amidst the whirling machinery, but the miracle is brought off all day long. Somehow, without fuss or apparent effort, the correct bobbins get wound to the correct degree with fibre of the correct colour and weight. Hands plunge into spinning wheels and bars and emerge scatheless. Surely, here is a ready-made field for clinical science to study the nervous mechanism of coördination. But the pinnacle of the machine age is reached in the actual weaving "shed." This is a large stone-floored room crammed with looms. I was told that there had been 480 looms in this shed, and the information was proudly added that 68 had been removed in the interests of efficiency (not, mark you, safety!). I found it impossible to conceive that 10 more could possibly have been inserted into the available space. The really impressive things in a weaving shed are the deafening noise and the constant movement, and it is this combination which conveys the almost overpowering sensation of being in the very hub of the machine age. For a quarter of an hour after leaving the shed the ears feel numb and dead, and the head in a whirl. The shuttle on each machine moves to and fro several times a second, and the machines are so close that a big man can scarcely squeeze through sideways. In addition, there are overhead belting and shafting. I was informed that deafness is rarely encountered in claims for compensation, that even the slightest accident such as a cut finger is unusual, and that any more serious mishap is almost unknown. The operatives start as soon as they leave school and rapidly acquire a machine sense.

I had never understood how the weft was insinuated through the warp and had visualised a process like darning where the weft thread is carried over and then under the warp threads. But my imagination failed at conceiving a machine to do this. Of course, the process is managed quite differently. It really begins at an earlier stage. The warp is supplied on a cylindrical roll as a number of single, parallel threads. This roll is placed on a stand and each thread or group of threads (depending on the design of the fabric to be woven) is picked out by hand with a sort of crochet hook and drawn through and tied to a ring attached to a horizontal bar lying parallel to the roll. (Picking out these threads all day long is the most soul and eye destroying job I can conceive.) Each thread of the warp is thus separately controlled by the little metal ring to which it is attached. The bar carrying all these rings falls horizontally into place in the loom. The process of weaving then consists of spreading alternate warp threads in opposite directions in a vertical plane. A bobbin carrying the weft thread is then shot across the machine from side to side through the Vs formed by the warp threads and is hammered into the notch of the V by a heavy bar moving synchronously with the weft bobbin. The next movement of the machine spreads the warp threads in the opposite direction and the weft bobbin shoots back to its original side and is again hammered home. If different colours are being used, there is a separate bobbin for each colour, and an automatic adjustment determines the number of times each bobbin is used. The colour of the warp threads is, of course, the same from beginning to end. It is a fascinating and dazzling spectacle to watch the flashing to and fro of the bobbins, the gradual growth of the pattern and the rapid movements, in exact synchronisation, of every part of the machine. This multiplied by 480, plus the accumulation of noise, provided enough stimulation for my nervous system to last me a week.

The production of clothing from wood pulp and coal by-products is one of the many processes embraced in the industry of plastics. The modern developments of this industry provide a fascinating chapter in the history of science. In many cases the ersatz is more durable and suitable for its particular purpose than the natural material previously used. Certainly natural cotton has few if any advantages over rayon, and although rayon "wool" or "silk" is not as warm as the natural product it is almost as lasting and considerably cheaper. Materials can be as attractive both in colour and design. In fact, the last thing anybody with the slightest acquaintance with the industry would do is to laugh at ersatz clothing.

They were arranging the holidays at Health House and the massive building was thronged with practitioners. Under the State Medical Service each had a month's vacation, half of which, however, had to be spent doing somebody else's job. For the first few years this had given rise to a certain amount of friction, evasion and even intrigue, so now for one and all it was being decided by the drawing of lots, which was taking place in the Great Hall.

In a lobby a distinguished gynæcologist was making lamentation. "An assistant in a Welsh colliery practice! I ask you!" The others laughed sympathetically. "I've got to go to a mental hospital," said a surgeon, "and if there's one thing I hate ..." "What about me," said a small, pale man bitterly, "I, who get sea-sick on the Serpentine, have got to go to New York as ship's surgeon." The harsh laughter disturbed the country GP who on the back of an envelope was explaining to a testy consultant how he got from Lower Rumbling to Upper Wilting, at both of which places he had surgeries. "Some of the bottles haven't got labels, but I expect you'll know them by their smell. Anyhow you won't be in a worse mess than I—a fracture clinic! Heavens! What's a good book?"

An angry, surly, sardonic hum rose from the room. "It's Popplecock we've got to thank for all this," said a skin specialist darkly. He was sentenced to fourteen days in industrial Wigtoun and felt vindictive. "Yes, Popplecock, the Minister for Positive Health, he got it passed at last year's conference. I'm waiting to see what he draws himself." He looked at his watch. "He's almost due now." In the Great Hall a hoarse voice was calling the names and a line of anxious men and women were streaming up to the central band-stand platform where a giant top-hat rotated briskly. As each went by he put his hand in and withdrew a slip. Some read their slips immediately, most when they got down on to the floor, a few didn't dare look until they were outside. "John Popkins, James George Poplington, Henry James Popplecock ..." The Minister was a jaunty little extrovert; he felt pleased with himself and the world in general; everything turned out all right for him, simply because he ignored things that didn't and exercised a certain amount of—er—foresight. He took his slip, read it as he sauntered down the steps, and laughed—or did he start to laugh a fraction of a second before he read it? "What have you got?" asked one of a savage group, waiting for him at the bottom. The Minister handed him the slip. "You will proceed to Aylesbury and for 14 days act as Editor of *Lancet*."

* * *

I had always been rather windy of female medical students, never more so than when one came and watched us taking blood for Wassermanns. We had been doing from 12 to 16 a morning. ("Nothing to worry about, mother. Just a little prick. Why, mother, what are you worrying about?" Each time I said them the words sounded more hollow.) Standing there with the utmost charm she watched us driving confidently into the thin, groping wildly in the succulence of the fat; the strain grew so bad that I cracked. "Here," I said, handing over the syringe. "Do it on me, and we'll see if it hurts or not." She did, and it hurt like hell. "You do it on me," she said. "It's only fair." Seizing her condyles in a grip vice-like with agitation, I did what seemed a model puncture. "Hurt?" I said. "No," she said, biting her lips, "not at all." But later on she reported throbbing and told her colleague that she expected never again to have the use of the vein; and later still, when they came to tea, she exhibited with unfeeling pride a large bruise on the condyle. My confidence, never great, ebbed to nothing. I write now to report that Sydney Smith knows what he is talking about. "Women," he says (*Forensic Medicine*, p. 111), "are much more easily bruised than men, owing to the greater delicacy of the tissues. A slight pressure with the fingers on the arm of a woman, especially if she is stout and not accustomed to work or exercise, may produce a definite bruise." To show that no account of her charm could be exaggerated, I ought to say that we added this insult to her injury, and she affects to remain our friend.

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

SIR WALTER WOMERSLEY's unsatisfactory reply to a question asking whether he will now appoint pensions appeal tribunals "in view of the fact that medical men of suitable training and experience are now available" was that it would be done "as soon as practicable," and Mr Arthur Greenwood, on behalf of the Labour Party asked for time to be allocated to an early discussion of this subject There are said to be some thousands of cases already in which reference to an appeal tribunal would be desirable and it is recognised that the setting up of this body after the last war, in 1919, was a very useful measure The total number of doctors required for the work is not great, and if a beginning was made by establishing one tribunal for each civil defence region, with an officers' appeal tribunal in addition in London the immediate need would be met The number of senior officers of the Army Medical Service who have reached the age of retirement, or who are retiring after holding the rank of major-general for four years can be calculated and this field of choice alone would provide men of long Service experience, administrative ability and professional standing Men are also retiring from the other two Services under the age-limit, and others are being invalided out Apart from the Services there are retiring medical officers of health, many of whom have had service experience, and retiring medical officers of the Government and other services The pensions appeal tribunal of the last war was a tribunal of the House of Lords, appointed by the Lord Chancellor Its members were a barrister or solicitor of not less than seven years' standing, a disabled officer or other rank (for an officers' or O R tribunal respectively), and a doctor The legal member acted as chairman and was often a county court judge, the military and medical members acted as assessors In practice the doctor was also usually a man with Service experience, this judicial constitution with a background of Service experience made the tribunal a valuable body

Even if, in the first instance, more than one tribunal for each civil defence region were set up it would be possible to find twenty medical men of high standing and long Service experience without calling on the hardworked general practitioner, or on the younger men required for active employment in the forces or in the hospitals Some of the men who retire from the Services do enter other employment, but there are certainly enough available to set the tribunals on their feet It is hoped that the Minister will bow to the arguments which will be put before him, but his resistance up to date has been difficult to understand At present an application for a pension which has been refused by the Ministry can only be reopened by bringing personal persuasion, usually through an MP, to bear on the Ministry If this is successful the papers of the case are referred for opinion to one of the Service departments But this arrangement means that the Minister is appointing a doctor of his own choice to reconsider the case and smacks too much of a combination of judge, jury and appeal court, combined in the Minister, and is unfair to the Service department concerned It does not compare for a moment with an appeal to a duly constituted court appointed by the Lord Chancellor All Service authorities would welcome these tribunals and the British Legion appreciates how much a judicial appeal means to the men and women concerned

QUESTION TIME

Pensions Appeal Tribunals

Dr HADEN GUEST asked the Minister of Pensions whether he was now in a position to appoint pensions appeal tribunals, in view of the fact that medical men of suitable training and experience were now available —Sir W WOMERSLEY replied A few doctors well qualified for pension work have recently become available and have been engaged by my department to meet its increasing requirements and to replace younger men released for service with the forces, but the evidence shows that the general position is becoming more rather than less difficult Therefore, I can only repeat my undertaking to set up pensions appeal tribunals as soon as practicable

Dr GUEST Does the Minister know that considerable numbers of medical men who have been serving in the Armed Forces become available at regular intervals when seniority or the fact that they had held certain rank for a period of four years necessitates their retirement, that they are men of long service, administrative experience and high medical standing and that at the present time these gentlemen are very often not able to find suitable work and could be placed as members of pensions appeal tribunals with very great advantage to themselves and to the country ?—Sir W WOMERSLEY My director of medical services is in constant touch with the director of the medical services of the Armed Forces Doctors who have been discharged from these forces have been sent to my department, interviewed and employed —Major J MILNER Is the Minister aware that quite a number of the members of this House are wholly dissatisfied with the position, and is he prepared to submit the evidence to which he referred to a committee of members or to his own advisory committee ?—Sir W WOMERSLEY Certainly, I am just as dissatisfied, but you cannot make bricks without straw, and until I get the right men I cannot do anything —Major MILNER That is precisely what the Minister can do

Mass Radiography Apparatus

Mr W J THORNE asked the Minister of Health what was the cost of mass radiography apparatus, are local authorities called upon to pay the purchase tax, and whether the Government would make a grant or allow a special loan to be made for the purchase of these instruments —Mr E BROWN replied The production of the standard apparatus has not yet reached a stage at which its cost can be closely determined, but it is expected to be in the region of £1500 Apparatus of this kind is not, I understand, subject to purchase tax It is not proposed to make special grants towards this particular item of cost to those county councils and county borough councils who will be concerned, but substantial Exchequer assistance is being given towards the cost of the treatment of tuberculosis Sir FRANCIS FREMANTLE Is the scheme for training doctors and mechanics to deal with this most complicated apparatus in full swing and able to keep pace with the supply of instruments ?—Mr BROWN Yes

Tuberculous Men and Military Service

Mr RHYS DAVIES asked the Minister of Labour whether he had considered the protest from the Manchester city council to the effect that within the city 328 cases discharged from the forces had been referred to the local health authority for treatment for tuberculosis, *that 39 cases of men* suffering from that disease were known locally before enlistment and that 4 were known to his ministry before being called up, and what reply he had tendered to the council's protest —Mr E BEVIN replied I have not yet received the resolution referred to, but inquiry is being made He added that he had not read the report of the council's discussion Until he received the question he did not know that the discussion had taken place He had sent for a full report of what was said, and he could not prejudge the matter When he had the report he must consult the medical boards which passed these men —Mr HENDERSON Is it not over a week since this question was handed in ?—Mr DAVIES Why does the Minister not adopt a suggestion which has been made very often ? As the full medical records of the vast majority of *men joining the forces are to be found* in approved society records, why does he not consult them before the men are taken into the forces ?—Mr BEVIN My hon friend knows that there is nothing which represents such poor information on medical conditions as approved society certificates —Mr DAVIES The Minister has been a secretary of one ?—Mr BEVIN Yes, I have

Glasgow Smallpox Epidemic

The Secretary of State for Scotland informed Mr T, E GROVES that it was not proposed to take proceedings against the shipping company responsible for the steamer from Bombay which arrived in the Clyde on May 29 last and in which there was discovered a case of smallpox The shipping company was not responsible for the failure to notify smallpox on the ship since the ship's doctor had diagnosed the case as measles complicated with pneumonia Obviously ship owners and shipmasters could not carry out any of the duties they had regarding smallpox on shipboard until its existence on the ship was recognised Nor did any blame attach to a ship's doctor who made a mistaken diagnosis in good faith Smallpox was difficult to distinguish in its early stages from measles The case was first recognised as smallpox on admission to hospital

In answer to a further question Mr Johnston stated that the total amount paid by Glasgow corporation for lymph used during the recent smallpox outbreak was £5102, of which £1075 is due to be recovered from the authorities of adjoining areas to whom the corporation issued supplies These figures do not include lymph obtained by the corporation through the Department of Health for Scotland which is valued at about £6000 The total amount paid in respect of fees for vaccinations performed during the outbreak was £10,469 , and 358 doctors and 190 senior medical students received fees for vaccinations the highest amount paid to any one doctor being £271 2s 6d

Typhoid and Paratyphoid Fever

Typhoid and paratyphoid fever became separately notifiable only towards the end of last year The number of cases notified in England and Wales in the past five years has been 1937, 2150 , 1938, 1321 , 1939, 1479 , 1940, 2848 , 1941, 4762 In 1941 there was an exceptional outbreak in the Liverpool district (Mr Brown replying to Sir E Graham Little.)

Incidence of Diphtheria

Mr Brown informed Mr J Griffiths that the number of cases of diphtheria notified during the first three quarters of this year was 29,939 This represents a decrease of about 6500 on the corresponding period last year The provisional mortality figures for the first half of 1942 show a decrease of 0 8% on the corresponding figures for 1941 As the disease is most prevalent among children it is being combated by the Government's policy of advocating immunisation of all children under 15, which has already resulted in the immunisation of over 3 million children since the beginning of 1940 —Prof A V Hill Does the Minister expect to get sufficient children immunised by propaganda alone, against the counter-propaganda of interested agencies financed by sentimental old women ? Mr Brown Yes, I expect propaganda methods to be sufficient —Mr W Leach Is the Minister aware that all his efforts so far have not reduced the death rate at all ?

British Troops and Yellow Fever

Mr Alfred Edwards asked the Secretary of State for War whether any cases of yellow fever had been diagnosed in British troops in any area in which they had been stationed since the commencement of the present war —The Secretary of State for War informed Mr A. Edwards that three cases of yellow fever had been diagnosed in British troops since the beginning of the war He added that vaccination against yellow fever of troops proceeding to endemic areas was introduced before the war, and has been continued without interruption. Most of the vaccine used is manufactured in this country, but some supplies are obtained from the United States of America

Mr Leach asked how many doses the British Army in Africa took in 1941 of yellow fever vaccine, virus 17D, manufactured by the Rockefeller Foundation , if he was aware that this vaccine was suspected of having caused 28,000 cases of jaundice in American troops with 68 deaths during the six months January to June, 1942 , whether there had been any jaundice in the British Army amongst soldiers inoculated with yellow fever vaccine , and whether he had made any inquiry into the possibility of harmful effects of the yellow fever vaccine now being used on British soldiers —Sir James Grigg Without instituting protracted inquiries locally it is impossible to say how many of the doses of yellow-fever vaccine administered to British troops in 1941 were manufactured by the Rockefeller Foundation I am aware that certain batches of this vaccine have been suspected of causing cases of jaundice among American troops None of the cases of jaundice which have occurred among British troops can be attributed to the inoculation against yellow fever The effects of inoculation are always carefully watched and no harmful effects among British troops have been noticed as a result of inoculations against yellow fever

Incidence of Duodenal Ulcer in the Army

The proportion of men invalided from the Army suffering from duodenal ulcers is about 11% of the number invalided on account of all diseases There is no evidence to show that Army life renders men more liable to duodenal ulcers than they would be in civil life and no special inquiry is necessary (Sir J Grigg replying to Sir I Albery)

Medical Committee on Bread

Sir E Graham-Little asked the Parliamentary Secretary to the Ministry of Food whether the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council now replaced the scientific advisers who had been, before February, 1942, responsible for the constitution of the bread supplied under the control of the Ministry —Mr W Mabane replied The advisory committee, as its name indicates, is concerned with foods which are rationed It has not, therefore, considered bread

Electrical Hearing-aid Apparatus

Mr W Brown asked the President of the Board of Trade what steps he was taking to ensure that a sufficient supply of the special dry batteries necessary for electrical amplifying valve types of hearing apparatus for the deaf shall be available —Mr H Dalton replied Last year my predecessor arranged that all new hearing aid apparatus should be made to take a standard battery, which could be supplied without undue difficulty, and most existing sets have been converted to use this type of battery I have now arranged for an increased and improved production of the special batteries required for apparatus, which, for various reasons, cannot be converted

Colonial Medical and Nursing Services

The Under Secretary of State for the Colonies informed Mr Creech Jones that the information available in the Colonial Office showed that 2 medical women had been appointed in the colonial services since the war and 219 nurses He emphasised, however, that there were many appointments made locally of which the Secretary of State had not received information

Seamen and Frost-bite Injuries

The Parliamentary Secretary to the Ministry of War Transport informed Mr Walter Edwards that full instructions had been issued for the prevention and treatment of frost bite among wrecked seamen Each man was provided with a rubberised protective suit to guard against exposure in lifeboat or raft, in addition to the means provided in the lifeboats and rafts themselves, for protecting the occupants against exposure. Specially designed protective clothing was issued to crews of ships employed in Arctic waters Oil was also provided for further protection and for massage, but he was not yet satisfied that the importance of using this oil was properly understood by seamen

---

PALESTINE

BLOOD SEDIMENTATION IN PULMONARY TUBERCULOSIS

At the hospital in Safad 732 blood-sedimentation tests have been carried out on 217 cases of pulmonary tuberculosis The Linzenmeier method was used, and the results were found to run parallel to the clinical course of the disease , the test, in fact, was a more accurate guide to the condition of the patient than were sputum tests for tubercle bacilli It was regarded as being significant in prognosis since cases with an accelerated sedimentation-rate during the whole period of observation either died or left hospital showing no improvement The rate was influenced by menstruation, rising by 30–100% before a period

LABORATORY DIAGNOSIS OF TYPHOID

In a survey of the bacteriological and serological findings in 786 cases of typhoid seen at the University Hospital, Jerusalem, during the past 12 years, I Gurewitch reports that during the first 7 years 90% of cases were diagnosed by the Widal test, and a positive blood-culture was obtained in only 10% In the last year the organism has been isolated from the blood in 44% of cases The reliability of the Widal test has been confirmed by the findings in many thousands of tests in the hospital laboratory The reaction appears a few days earlier in children than in adults A high titre of O agglutinins in the serum of a typhoid patient indicates a favourable prognosis Occasionally an unspecific Widal reaction is seen in cases of malignant disease with cachexia

During 1940–41 the numbers of cases of typhoid and paratyphoid in Jerusalem rose to epidemic level The severity of the disease also increased thus in 1935–39 there were no deaths among 114 cases admitted to the University Hospital, while in the epidemic there were 11 deaths among 135 cases Braun and Dreyfuss, writing in the journal *Harefuah*, describe the clinical course as being longer than usual, and the toxæmia and the tendency to relapse more pronounced Collapses, rigors and delirium were common, and ulceration of the throat was seen in a relatively large number of cases, progressing in one case to cancrum oris with death Other complications were jaundice, pneumonia and abscesses in the muscles Avitaminosis was common; especially deficiency of vitamin C and of vitamin-B complex Chemotherapy was used with results which will be reported later Small blood-transfusions were useful as a supporting measure Extra vitamins were given only to those cases which showed a deficiency

ACROPARÆSTHESIA

In the same journal I Schlenderer reports the treatment of acroparæsthesia with injections of vitamin B and with short-wave therapy Six cases treated in this way all recovered

Letters to the Editor

REHABILITATION CENTRES

SIR,—Members of the British Orthopædic Association recognise the value of measures already adopted by the Ministry of Health in introducing rehabilitation into EMS orthopædic, fracture and accident services They are not, however, satisfied that the later stages of rehabilitation have been adequately developed throughout the country, and for this particular purpose they urge the importance of establishing special rehabilitation centres, in association with existing orthopædic, fracture and accident services, under the same administrative and surgical control, but as a rule geographically separated in order to avoid the hospital atmosphere, and affording all facilities needed for the completion of treatment right up to the stage when work can be resumed From undoubted evidence of grave wastage of manpower through accidents, they believe that the developments recommended are of immediate urgency in the prosecution of the war

We feel it should be clearly understood that the orthopædic surgeons of the country are wholly in favour of this constructive medical and sociological movement Rehabilitation should begin very soon after the accident or wound, and be carried on throughout the patient's period in hospital in the form of occupational therapy and gymnastic or remedial exercises There remains as a logical and very necessary development the organisation of centres where the final and more concentrated stages of rehabilitation are given to enable the patient to be returned to the Services or to industry with the least possible delay

G R GIRDLESTONE,
President of the British
Orthopædic Association

Headington, Oxford

TIME OF UNION IN FRACTURED TIBIA

SIR,—Much has been heard of the fractures which were said to unite more quickly thirty years ago than they do today It is said that fractures of the tibia then united in 8 weeks, whereas now they unite only in 12 or more weeks If this was true it might be reasonable to suspect measures of treatment which have been introduced since then—the use of plaster, the unpadded cast, and the more general practice of rigid and continuous immobilisation But I submit that it is not true, and that fractures uncomplicated by distraction or infection are uniting as quickly today as they did then I suggest that most fractures of the tibia in adults were never soundly and safely united in 8 weeks—that they were united only firmly enough for the patient to be discharged from hospital, after which some fractures went on to complete union, some to malunion, and others to non-union, according to the stage of repair which had been reached in that unduly short period

If this interpretation is in doubt, let us consult the literature of the day when this rapid union was supposed to be occurring—the literature of thirty years ago In 1912 Robert Jones wrote, " Both malunion and non-union are common I see such cases every week We are all misled as to the period of consolidation of bone " Again he wrote " We must realise that the academic period of consolidation authoritatively asserted is not accurate, and that bones which appear firm to the hand will yield after many weeks " A leading article in the *British Medical Journal* thirty years ago reads " The periods of allotted time for consolidation of a long bone after fracture should be revised, that is, lengthened, since yielding at the site of fracture often appears after the case has passed out of the hands of the surgeon "

It must of course be recognised that distraction, loss of blood-supply and infection are important delaying factors It must be recognised that some fractures are much slower in uniting than others (and this also was common experience thirty years ago) But let us accept that complete and continuous immobilisation in plaster neither accelerates nor delays union, it simply allows union to occur at a normal rate without interruption Let us accept that a quickly uniting fracture requires a short period of immobilisation, a slowly uniting fracture a long period, and that every fracture will unite if it is immobilised long enough Let us remember that in deliberately increasing our minimal period of immobilisation from 6 or 8 weeks to 10 or 12 weeks we are accepting the advice of surgeons of thirty years ago, who told us that their periods had been too short Finally, let us remember that the malunion and non-union which they saw every week have now virtually disappeared

Liverpool R WATSON-JONES

SPINAL ANÆSTHESIA FOR CÆSAREAN SECTION

SIR,—May I correct the statement in your annotation of Oct 10 (p 432) that the exact dosage of heavy ' Percaine ' (now called ' Nupercaine ')-was not given in my paper? The exact dosage in every individual case is given in the tables at the end, from which it will be seen that 89 cases were given a dosage of 2 5 c cm This is the dosage I have found most appropriate

In regard to the 8 failures, the cause in some cases was puncture of one of the meningeal veins with consequent blood-stained cerebrospinal fluid, resulting in fixation of the nupercaine solution before it had risen high enough (nupercaine is very rapidly fixed), in other cases (among our earliest) too much time was lost in turning the patient on to her back after injection of the nupercaine, too early fixation again being the result Another possible cause may be that if the Trendelenburg position is not sufficiently attained the solution may fail to pass the lumbar curve, when, of course, the solution does not travel higher than the 1st lumbar vertebra This is a point to remember in the technique of administration for cases of lordosis such as may be met with in patients with rickets or congenital dislocation of the hips The lumbar curve can be partly taken out by making the patient draw her knees up, which we now do as a routine We have had practically no failures in the last 100 cases

Since writing my paper on which your annotation was based, I have done a further 37 cases under heavy nupercaine, with no maternal deaths, the total successful cases now being 158 I am more than ever convinced that heavy nupercaine is the ideal anæsthetic in the properly selected case

Croydon RUFUS C THOMAS

PALSY AND INTRAMUSCULAR SULPHONAMIDE

SIR,—The three cases of peripheral nerve palsy reported by Elkington in your issue of Oct 10 (p 425) prompt me to put on record a similar case which I have encountered The patient was a man of fifty-seven years who had received a number of injections of sulphapyridine for the treatment of pneumonia The last of these injections was given into the back of the thigh and the point of the needle penetrated the sciatic nerve causing sudden pain to shoot down the limb The needle was withdrawn half an inch and the injection continued After a latent period of a few days severe neuralgic pain in the sciatic distribution developed and there was paralysis of the calf muscles, toe flexors and tibialis posticus

After some weeks, during which time the severe pain continued, exploration of the nerve was undertaken The point of damage to the nerve could be detected easily by the presence of local tenderness and slight thickening At operation it was found that the sheath of the nerve was adherent to the surrounding tissues and to the nerve trunk on the medial side The trunk of the nerve was itself inflamed for about a quarter of its width Neurolysis was performed and there was some relief of pain after the operation The present position is that, eight months after the injection the motor weakness is more or less unchanged and there is still complete loss of sensation in the sole of the foot The greater part of the neuralgic pain has disappeared

It is evident that sulphapyridine in concentrated solution can damage nerve tissue permanently Apart from the obvious necessity to avoid the main nerve trunks when giving an injection one wonders how far it is safe in open wounds to use sulphapyridine powder liberally when it is possible that a nerve trunk may be laid bare in the depths of the wound In view of the damaging effect of sulphapyridine on nerve tissue it is clear that the dusting of open wounds with the powder must be rigorously avoided if a nerve trunk is exposed and more especially if partial damage to the nerve by the injury is actually observed

Liverpool NORMAN ROBERTS

PLANNED NUTRITION

SIR,—In your constructive leading article of Oct 3 and the others which have lately urged the formation of a Nutritional Council there is a point which does not seem to have been discussed If a National Nutritional Council does come into being in this country, could not more consideration be given within such a body to the whole directional policy for planned nutrition as it would affect the future of our Crown Colonies?

Parkstone Dorset D G FITZGERALD MOORE

MEDICAL PERIODICALS

SIR,—The maintenance of stocks of periodicals has become a serious problem, publishers' stocks of important journals have been lost by enemy action, scientific libraries at home and abroad have been destroyed and current issues lost in transit The cooperation of all possessors and receivers of periodicals is needed to ensure that important journals are not unobtainable after the war May we ask all private owners of medical periodicals not to consign their collections of back numbers for salvage without the most careful consideration? All librarians will, we know, be pleased to advise inquirers as to the most useful disposal of their unwanted journals

G F HOME,
Librarian Royal Society of Medicine
W R LEFANU,
Librarian, Royal College of Surgeons

SPERM SURVIVAL

SIR,—The article by Tynen and Ranson in your issue of Oct 10 is of value in emphasising the fallaciousness of examining seminal fluid that has been in contact with rubber sheaths I doubt, however, whether transference to glass, or the preliminary treatment of the condom as advised, will eliminate such fallibility, although it would tend to decrease or modify its extent Such errors as are mentioned do not occur when the specimen is obtained completely fresh by the patient himself producing an ejaculation in a room adjoining the examination room. This method has revealed motile spermatozoa in patients who have had several previous reports of non-motile spermatozoa I make a point of allowing the patient to observe the motility of the spermatozoa under the microscope, and it is amazing what tremendous relief and satisfaction this gives to one who is under the impression that he can produce only "dead spermatozoa" Sometimes his whole outlook is changed, and he no longer minds that the number of spermatozoa is few, or that sterility may be associated with this fact For similar reasons, in the absence of complete azoospermia, it is inadvisable to give an absolute opinion on the impossibility of pregnancy After an initial examination of spermatozoa obtained by this method, condom specimens are satisfactory for later estimation of the number of spermatozoa, and the influence of hormone treatment on this number, if any. Incidentally, Charny and Meranze (*Surg Gynec Obstet* April, 1942, p. 836) urge biopsy of testis to exclude those cases in which hormone therapy cannot possibly be of any use

I have never had any complaints, or unfortunate sequelæ, from using this direct method of producing specimens of seminal fluid, but I have heard of one case where the patient blamed the doctor for being the cause

Obituary

LEONARD KIDD

M D DUBL

DR Leonard Kidd died in his eightieth year at Enniskillen, co Fermanagh, on Oct 2 after a long illness He was one of the best-known surgeons in Ireland, and was on the staff of the Fermanagh county hospital for over forty years Educated at Trinity College, Dublin, and the Carmichael School of Medicine he qualified in 1887, taking the gold medal in operative surgery, and after a term as house-surgeon at the Richmond Hospital in Dublin and as assistant master of the Coombe Hospital, he became, while still a young man surgeon to the county hospital at Enniskillen Here he had sole medical and surgical charge and quickly established a sound reputation as a wise practitioner and a skilful surgeon, and his practice became one of the largest in the Irish provinces Largely owing to his energies the hospital was transformed into a modern, well-planned institution thoroughly fitted for its work as a county hospital Although busy with his professional work Kidd took an important part in public medical affairs and was for many years one of the most active members of the council of the Irish Medical Association, of which body he became president. He also served as president of the Ulster Medical Society In 1906 he contested the office of direct representative of the medical profession of Ireland on the GMC and defeated the sitting member, the late Sir William Thomson Kidd retained his membership of the council until his retirement a few months ago During the last war he served for a time as major RAMC in the 83 (Dublin) General Hospital at Boulogne Leonard Kidd was a magistrate and deputy lieutenant for the county of Fermanagh, and both as a doctor and as a citizen he was held in honour in the county where he worked for so long

[illegible]

LOUIS COLTMAN PARKES

M D LOND, D P H

THE death of Louis Parkes deprives us of one of the most respected men of his age in public health—a man of sound judgment, an alderman among his confreres In his early career he was assistant lecturer to W H. Corfield at University College, London, when he got the bias towards the structural side of public health that was natural in the days when childbed fever and royal attacks of typhoid were attributed to defective drains Typhoid carriers and still less diphtheria carriers had not been thought of nor had the relation of shellfish to the propagation of typhoid been discovered Yet even then one of the qualifications demanded of the typhus nurse was that she had been salted by an attack of the disease It was in this epoch that Parkes succeeded the veteran E C Seaton as medical officer of health for Chelsea, and all that he did there is written in annual reports which can still be read with profit Chelsea was already for the most part a built-up area, and there were slums within it with which he dealt effectively He was closely identified with the Royal Sanitary Institute and the museum which bore the name of his uncle, E A.

Continued from the previous column

of his returning to an adolescent practice which he had only relinquished by dint of great effort One should therefore be aware of this possibility in a neurotic personality I have had no experience of examining a specimen of seminal fluid taken from the vagina or endocervix after coitus but apart from the difficulties involved it cannot give the same information as examination of an uncontaminated specimen of seminal fluid

Harley-street W 1 S L SIMPSON

Parkes, professor of clinical medicine at University College and founder of the science of modern hygiene To the regret of his public health friends Louis Parkes retired somewhat early from official work although he continued to advise H M Office of Works on sanitary matters But he started as a teacher of hygiene and he remained a teacher to the end "Parkes and Kenwood" was the companion and guide of sanitarians for two generations He went from Chelsea to a beautiful house at Holmbury St Mary where he lived with his daughter Joan until his death on Oct 11 at the age of 84

A N

FREDERICK GEORGE CHANDLER

M D CAMB, F R C P

Dr F G Chandler died at Newdigate, Surrey, on Oct 8 Born at Sutton in July 1885, and educated at the Leys School, he became a scholar of Jesus College, Cambridge, and took a first in the natural sciences tripos He qualified in 1911 from St Bart's, where he was house-physician and edited the *Journal* Before going abroad in 1914 he had worked at Ormond Street, Brompton and the London, his war service began as regimental doctor to the 2nd Argyll and Sutherland Highlanders and included charge of field ambulance and CCS On his return he was appointed assistant physician to the London Chest Hospital, where he was senior at the time of his death From 1922 to 1930 he was assistant physician and medical tutor at Charing Cross, then securing election to the staff of his old hospital, which he had meanwhile served as casualty physician He was also consultant to Midhurst and examiner in medicine at both Cambridge and Oxford

Elliott & Fry

Supporting Chandler's candidature for his Bart's appointment a well-known consultant remarked "His knowledge as a physician, his gifts as a teacher his energy as a worker, the staunchness of his character and his friendliness as a colleague would make him a very valuable accession to any hospital staff Less than that could not be said and more need not be said" Another stated that he frequently availed himself of his experience in the solution of difficult medical problems One of those he taught testifies "He was energetic, fiery, stirring and humorous His outpatient afternoons surged along, his ward rounds swept from bed to bed, but at the bedside he became gentle and—for him—leisurely He never frightened a patient, and he was angry if he thought anyone else was going to He often frightened students though, but never to the point of imbecility he would suddenly notice what he was about and rescue them He used to take one or two of us down to Victoria Park to see cases, and rode with us on the bus top, pointing out Georgian terraces going to seed, or Wren churches, and talking hard all the time" And these qualities which we see here in the making became ever purer and more refined in the discipline of successful practice His patients quickly became his friends, as was to be expected when he spared them any sort of physical or mental trauma It was to this end that he devised many instruments and designed the single-puncture thoracoscope with which to perform internal pneumolysis This was perhaps his greatest technical achievement, for in 110 consecutive operations performed without anæsthetic other than an occasional barbiturate only once did a patient become faint on the table All these cases were thus rescued painlessly from the disappointment of a failed artificial pneumothorax, and from the threat of a thoracoplasty And his colleagues also quickly became his friends He had the gift of calling out the best in a man, and his house-physicians were always prepared to give him their spare time without complaint He required extra notes on his cases for his own personal records and evenings were gladly spent in doing them to his satisfaction He was never afraid to ask the advice of a junior nor to consult a textbook if he was asked a question he could not answer, he never attempted to bluff his students—a point they sometimes failed to recognise Many a young consultant he helped through the lean years, when he gave advice he invariably supported it by making it a practical proposition

All through his working years Chandler wrote much for the professional journals He had no call to systematic writing and his papers embodied cross-sections of his thought of the moment His exigence about the form of their presentation was a fearful joy to the willing editor For two *Lancet* series he wrote little masterpieces treatment of bronchiectasis (1930) and its prognosis (1934) He had a flair for diagrams which told at a glance the findings of clinical examination and he taught students to embellish their notes with these graphic formulæ

Although essentially a general physician it was probably in the London Chest Hospital that Chandler found his spiritual home He came on the scene at the moment when X rays and surgery were beginning to revolutionise the practice of thoracic medicine, and he picked up the work at the point where Clive Riviere left it Both were artists and craftsmen, they were close friends and their outlook was very similar Committee work was not congenial to Chandler, but when severe bombing thrust on the hospital the problem of reconstruction he sacrificed his leisure and some sleep to thinking well ahead about the new problem of the private patient in the voluntary hospital

Chandler married Marjorie, daughter of Frederick Raimes, J P, of co. Durham, and they had three children, one boy and two girls It was his set purpose that they should all have some outdoor hobby and he bought a small estate of meadow and woodland in one of the most beautiful parts of Surrey transforming it with his own hands from virgin forest into garden At Newdigate he satisfied his love of growing things and entertained a succession of housemen from Bart's and Victoria Park Here, too, he faced his death sentence with the fortitude he had inspired in his patients He ordered his affairs, directed his household, and planned his garden, regretting only that he should not see it reach maturity He was not afraid of pain himself but hoped that it would not become unbearable

Happily it was an essential part of Chandler's character that he should gather round him those who follow on in his tradition and high principles Generosity and greatheartedness were inherent in him and those who worked with him will not forget his enthusiasm and intensity The memorial service at St. Bartholomew the Less on Oct 16 made this clear enough

DOUGLAS ARNOLD NEWBERY

M R C S, SURGEON COMMANDER R N

Douglas Newbery was born at Bath in 1902 and was educated at Weymouth College He had a great love of ships and when his father, the Rev L A McC Newbery, demurred to his going into the Navy, he determined to become a doctor and to enter the service that way At Guy's Hospital, where he began his medical training in 1919, he lived under spartan conditions, for his father's family was large and money was scarce He joined HMS *Keppel* in 1926, the year he qualified, and after various appointments at home and abroad, including two years attached to Gibraltar dockyard, he was appointed to the RN Hospital at Haslar as anæsthetist But he soon longed for the sea again and joined HMS *Sussex* in 1937 as PMO He was transferred to HMS *Repulse* in 1940 He was reported missing when she was lost last December and is now officially presumed dead

Laf

Though Newbery always regretted he was not executive officer, he was keenly interested in medicine and took every opportunity to widen his knowledge He was reliable and thorough and his independent was never satisfied with readymade opinions stood out for his absolute integrity and for his love of all that is best in music poetry and books He was a good allround athlete and a keen golfer During this war Newbery saw service from Arctic waters to Cape Horn and from Canada to Singapore, always hoping for action When the final action came one of his assistant doctors wrote "The medical arrangements that Newbery had planned worked well in practice, as like most things he did, they were well thought out" He was last seen in the sick bay, helping the wounded men who could be moved to get away to safety In 1932 he married Janet, daughter of Colonel and the Hon Mrs Bernard James, and leaves a son and two daughters

DOUGLAS YEOMAN RICHARDSON

MRCS, DLO, MAJOR RAMC

Major Douglas Richardson whose death on active service at the age of 30 is announced, was educated at Durham School and University He took the conjoint qualification in 1931 and after holding appointments at the West Herts, the West London and the Central London Throat hospitals he settled in Lincoln in 1931 where he took up a partnership in a general practice But his main interest was always in ear, nose and throat work and in 1939 he secured the DLO His consulting work quickly increased and he was appointed to the ENT department at Lincoln county hospital and became aural surgeon to the EMS hospital at Louth When he joined the RAMC it was to continue his special work in a military hospital

Richardson was a keen sportsman and till shortly before the war played rugby with the Lincoln club He was equally good at tennis and golf His patients and colleagues alike appreciated his conscientiousness, sincerity and charm and gave him their affection and trust He leaves his widow with four children

MARTIN DUNSMORE WINNING

MB GLASG, CAPTAIN RAMC

Captain Martin Winning son of the late Dr Thomas Winning of Sunderland, was killed in March by a sniper's bullet while attending casualties during the fighting in Rangoon A former pupil of Durham Boys School, he graduated from the University of Glasgow in 1938 After qualifying, he was house-surgeon in Whitehaven Infirmary and later assistant in a busy general practice in Darvel, Ayrshire He was commissioned in February, 1940, and soon afterwards was posted to India Winning's chief interest in life was medicine, and his patients and friends will recall how often his quiet confidence helped them He was 30 years of age and unmarried

SAMUEL GUISE GUISE-MOORES

KCB, KCVO, CMG MRCS

MAJOR GENERAL RAMC (RETD)

THROUGH the death of Sir Guise Guise-Moores on Oct 3 the Army Medical Service has lost a distinguished veteran and Cheltenham College, where he was educated, a good friend His real ability was backed by charm of manner and a fine presence, and his work well earned the many honours which he received Guise-Moores qualified from St Thomas's in 1888, obtaining his commission two years later, and first saw service in the Chitral campaign During the South African war his quality as an administrator was quickly recognised and his majority came to him as special promotion For the next eight years he was attached to the Scots Guards as surgeon major, but he returned to the RAMC in 1909 and was promoted lieut-colonel three years later During the whole of the last war he served at the front and was five times mentioned in dispatches, created CB and CMG and officer of the ordre Leopold In 1919 he was made major-general—again a special promotion—and in the same year he was appointed commandant of the RAM College and later DDMS of the Aldershot command Shortly after his retirement in 1923 he became house governor and medical superintendent of the convalescent home for officers at Osborne and he was a successful DMS at the Empire Exhibition at Wembley He married Miss Kate Louise Wood and they had one son He was 70 years of age

---

Notes and News

SIÈCLE MEDICAL

THE Metropolitan Edition of the *Siecle Medical* is published in Paris and has an office in the unoccupied zone at Vichy *It retains the format of a daily newspaper* costs two francs and is issued monthly "provisionally" It claims the largest circulation among medical papers in France and includes "the latest medical news from the whole world"—the second claim being hardly borne out by the contents which are largely concerned with "parochial" medico-politics Indeed, in a recent issue almost the only reference to medicine outside France is a notice of an article in *Wehrmacht*—the German military paper—which describes, in lyric though hardly scientific terms, an operation "as dangerous for the operator as for the patient" An anti-aircraft gunner was brought to the divisional dressing station with an unexploded 2 cm explosive bullet lodged in the left scapular region X-ray examination showed it to be in the dorsal muscles at the level of the sixth rib The surgeon "considerably worried at this unusual case," was not reassured by receiving information on the extreme sensitiveness of the exploding mechanism All the usual assistants were turned out of the operating theatre except two male nurses, the patient was covered with steel plates except for the field of operation, and the surgeon and assistants donned sterile gowns and steel helmets "Puis l'opération commence, angoissante, passionnante et delicate" The missile was exposed, withdrawn "by a gentle and prudent movement of the forceps" and removed by an assistant "with measured gestures" It is needless to add that the operation was crowned with success The other main articles on the first page consist of a reproduction of a broadcast speech by Dr Grasset, the secretary of state for health and the family, announcing the reorganisation of the profession and the formation of a Medical Corporation, an article on social medicine, which is defined as synonymous with preventive medicine, and the celebration of the fiftieth anniversary of the School of Anthropology in Paris Other articles deal with the non-medical treatment of enuresis, as set out by Professor Czerny in the *Deutsche Medizinische Wochenschrift*, the effects of eating poisonous fungi, which perhaps throws a sinister light on the food shortage, the difficulties in sterilising instruments which will be caused by the proposed restrictions on gas, a resolution of a departmental council of the Medical Order demanding restrictions in the number of medical students, and a decree setting up a system of preventive medicine for students at the University of Paris A whole page is given up to local medical news and another to answers to correspondents, all of which are concerned with conditions of practice &c and not with technical subjects The last of the eight pages is headed "Le Siecle Dentaire," and the small advertisements are largely of consulting-rooms to let ! From all of which it is clear that our colleagues in France have even more worries and troubles to face than the rest of the French population

University of Cambridge

At recent examinations the following were successful

DMRE

Part II—R A D J Bernhardt A B Donald H R Holmes Benzion Kounine Arnost Preiss R A Williams, and Hugh Wormald

On Oct 16 the following degrees were conferred by proxy

MB, B Chir—[illegible] Emrys Roberts, A J Rook, W F Felton Maurice Koettlitz, J B [illegible]-Mein, I N Darbyshire M M Brown, K H Lum, W P U Jackson and R J F H Pinsent

MB—John Mackellar

Medical College
83
LANCET

University of Sheffield

Dr H Le Brun and Dr W A Harney have been appointed demonstrators in anatomy

At recent examinations the following were successful

FINAL EXAMINATION M B, CH B

Parts II and III—H M A Ansari, Josephine Hall, J D H Linfoot, E R Monypenny, Ethel M Spedding, R L N Stewart and Joan Williams

Dysentery in Middlesbrough

Since Sept 10, 92 cases of Flexner W dysentery have occurred in Middlesbrough The disease was first confirmed bacteriologically on Sept 16, although for some weeks previously there had been cases of severe diarrhœa in the town which were ascribed to the consumption of raw fruit Most of the cases of dysentery were in children under five years, although some adolescents and a few adults were affected There have been 9 deaths, 8 in children under four years and one in a woman of fifty, these were toxic cases and except in the woman occurred in poorly nourished infants who were quickly dehydrated and did not respond to sulphaguanidine and the usual restorative measures Clinically, the cases were typical with a rise in temperature to 100°–102° F for several days with blood and mucus in the stool

All confirmed cases were admitted to the isolation hospital and some 250 other cases of diarrhœa were investigated bacteriologically The usual routine investigations were made but no common source of infection was found Samples of water, milk and ice-cream were examined with negative results It was obvious that spread was occurring from patient to patient, since in many instances several members of one family were affected Isolation of all cases in hospital resulted in the localisation of the infection and the prevention of further spread During the week ending Oct 17, only 7 positive cases have been admitted to hospital The outbreak seems to have been initiated by a small nucleus of infection occurring some time during July

Smallpox in Fife

Twenty one cases of smallpox have been reported from Fife this month Five families from Methilhill were involved in the first cases a mother and her four year old daughter, both of whom have since died, were admitted to hospital on Oct 7, a father, mother, six year old son and five year old daughter, a husband and wife, a young woman, and a six-year old girl the following day Eleven further cases, all contacts of the earlier ones, have been confirmed It is yet too early to say where the outbreak originated or what connexion, if any, it had with the Glasgow epidemic The cases were at first thought to be chickenpox and in view of this the Department of Health for Scotland have asked medical practitioners to report all doubtful cases to their local medical officer of health

Medical Casualties

The following casualties have been announced

Missing, presumed killed—T/Surgeon Lieutenant W W Tennant, MB GLASG, RNVR, HM Minesweeper *Leda*

Missing—T/Surgeon Lieutenant B H O'Neill, MRCS, RNVR, HMS *Sikh*

Wounded—Captain N J P Hewlings, MB CAMB, RAMC, WS/Captain T A Shannon, MRCS, RAMC

Medical Honours

The DSC has been awarded to T/Surgeon Lieutenant A W Clark, MD, RCNVR, for bravery, endurance and devotion to duty in action against the enemy in the Mediterranean, and to T/Surgeon Lieutenant Gillies Macbain, LMSSA, RNVR, for courage and devotion to duty in north Russian waters

King Edward's Hospital Fund

The King has appointed the Duke of Gloucester president of the fund in succession to the late Duke of Kent During 1941 the fund distributed £300,000 among the London voluntary hospitals and a further £2000 for district nursing work among outpatients The fund has also collaborated with the Ministry of Health in the survey of London's voluntary hospitals The recruitment centre has secured 1100 student nurses for the hospitals A contributory schemes committee has been set up—consisting of representatives from King Edward's Fund, the Voluntary Hospitals Committee, the Hospital Saving Association and the Hospital Saturday Fund—to consider the coördination of contributory schemes in London

Royal Society of Medicine

On Monday, Oct 26, at 2 30 PM, Mr B Maxwell Stephens will give his presidential address to the section of odontology He will speak on inferior protrusion and the advisability of early treatment and there will be a discussion afterwards On Oct 27, at 5 PM, at a joint meeting of the sections of medicine and epidemiology, Dr R C Wingfield, Dr Cyril Banks, Wing Commander R R Trail and Dr J B McDougall will open a discussion on the control of tuberculosis as an infectious disease

Medical Society of London

A general meeting of this society will be held at 11, Chandos Street, W1, on Monday, Oct 26, at 5 PM, and at 5 15 PM, Dr A Hope Gosse will give his presidential address on the health of the doctor

Eggs for Nursing Mothers

Mothers are to be allowed priority supplies of eggs for twelve months after the birth of a child, and in future it will only be necessary for doctors to issue an initial medical certificate to a nursing mother on the birth of the child

Photography in Industry and Science

The exhibition arranged by the Association of Scientific Workers will open on Oct 31

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

---

Appointments

ROSE, LOUIS, MRCS consulting neuropsychiatrist to the Lowestoft and North Suffolk Hospital

CHEFTINS, E M, MB LOND resident asst medical registrar at the Royal Free Hospital, London

*MCLAUCHLAN, J A, MD EDIN, FRCS orthopædic surgeon to Queen Mary's Hospital for the East End

*IBBOTSON, WILLIAM, FRCSE aural surgeon to Queen Mary's Hospital for the East End

* War time appointment

Colonial Service—The following appointments are announced

MACDONALD, R F, MD ABERD, DPH MO, Gold Coast,
CRAN, D L, MB MANC, DTM & H MO, Zanzibar,
MACLENNAN, N M, MD ABERD, DPH, DTM & H DMS, Trinidad,
WILSON, C, MB DUBL senior MO, Nigeria,
SIMON, D S LRCPE medical superintendent, Hendala Leprosy Hospital, Ceylon

---

Births, Marriages and Deaths

BIRTHS

BISSET—On Oct 9, at Perth, the wife of Captain G M Fraser Bisset RAMC—a son

BOWE—On Oct 14, at Dorking, the wife of Squadron Leader J C Bowe, MB, RAF—a son

CRAIKE—On Oct 10, at Ealing, the wife of Dr W H Craike, RAFVR—a son

FLINT—On Oct 11, in London, the wife of Dr H T Flint, Pillerton Hersey, Warwick—a daughter

GLADSTONE—On Oct 10, in London, the wife of Dr Gerald Gladstone—a daughter

HEWER—On Oct 12, the wife of Prof T F Hewer, MD—a daughter

MOLE—On Oct 15, at Tiverton, Devon, the wife of Lieutenant R H B Mole RAMC—a son

NASH—On Oct 10 at Cheltenham, the wife of Squadron Leader D Ellison Nash, FRCS—a son

ROBERTS—On Oct 11, at Bristol, the wife of T/Surgeon Lieutenant J A Fraser Roberts, RNVR—a daughter

STORRS—On Oct 14, the wife of Mr Guy Storrs, FRCS, of Bedford—a son

VAUGHAN JACKSON—On Oct 16, in London, the wife of Surgeon Lieut Commander O J Vaughan Jackson—a son

MARRIAGES

DISMORR—ROBERTSON—On Oct 13, at Frognal, Edward Stewart Dismorr, MB, to Betty Robertson

KENNETT—CRAIG—On Oct 13, at Edinburgh, Alexander Kennett MRCS, surgeon lieutenant, RNVR, to Alison, younger daughter of the late Sir Maurice Craig, FRCP

MERSON—HOUGHTON—On Oct 9, at Zanzibar, George Polson Merson, MB, to Norah Houghton

DEATHS

BRAZIER CREAGH—On Oct 10, George Washington Brazier Creagh CB, CMG, LMS, RAMC (retd) aged 84

BROOKS—On Oct 14, at Swanage, Walter Tyrrell Brooks MA OXFD, MB LOND

PARKES—On Oct 11, at Holmbury St Mary, Louis Coltman Parkes, MD LOND, aged 84

RODOCANACHI—On Oct 13, at Stalybridge Cheshire, Ambrose John Rodocanachi, MD LOND, FRCS, aged 68

SOME AIDS TO OPERATIVE SURGERY

W A COCHRANE, M B EDIN, F R C S E
SURGEON IN CHARGE, PRINCESS MARGARET ROSE HOSPITAL EDINBURGH, LECTURER IN ORTHOPÆDIC SURGERY TO THE UNIVERSITY OF EDINBURGH

METHODS of using a knife in operative surgery receive little attention in textbooks or discussion It is not surprising that those who are expert operators should take the matter for granted, but, for those who are beginning surgery, it should be of use to consider how this instrument, so fundamental in importance, may be used to the best advantage It is necessary to know not only what should be done at an operation, but also, how it should be done technically Watching, or even assisting at, operations does not readily bring out all that is required by the surgeon when he begins to operate for himself

POSITION OF THE PART

The operation should not begin until the part has been put into the best position, in order, when possible, to put the tissues under the moderate tension required for clean knife dissection, and to carry them forward into the field as the dissection proceeds Many potential difficulties of an operation need never arise, if the surgeon gives this special attention Veins give the chief trouble in many operations, if they are put moderately on the stretch, they do not get engorged and give a minimum of interference For example, in operations at the root and in the deep triangles of the neck, the head and shoulders are raised on sandbags and the head turned to one side, with the shoulder depressed by the pull of a clove-hitch round the wrist In operations on the upper limb and axilla it is often of assistance to abduct the arm on a narrow table, placing a sandbag beneath the elbow It may add seriously to the dangers of an operation if the dissection is allowed to proceed on slack tissues Work in the dissecting-room affords little indication of the manner in which the resilience of the living tissues can be utilised in surgery

THE KNIFE AND THE INCISION

The shape, weight and balance of the knife should be studied The blade should be fairly broad, bulging to a belly near the point The point should be far back, in line with the back of the blade If the blade is too narrow, and if its back and cutting edge slope equally towards the point, it adds to the difficulty of knife dissection, which ought to be done with the belly and not with the point If the knife is wrongly shaped, badly balanced and held wrongly, it becomes all the more difficult to avoid the puncture and division of important structures The student's dissecting knife is not always well-shaped and balanced, and some of the blades and knives in common use at operation are poorly designed

The incision should be long enough The handle is held low The belly of the knife is pressed against the skin, made tense by the pressure and separation of the index finger and thumb of the left hand which over-arch the blade and accompany it on its course The left hand dominates the right in making the incision and a clean cut down to and through the subcutaneous tissues The underlying structures are exposed and rise into the wound Sometimes the tips of the index fingers, covered with gauze, are put into the wound at this stage and firmly but gently separated, to give additional exposure of fascia and aponeurosis In an operation for inguinal hernia, for example, this assists in exposing the external oblique aponeurosis, the cord and the external abdominal ring

THE DISSECTION

The rest of the dissection is not made by cutting straight through the tissues The belly of the knife is used on the slant, sloped or keeled over a little on its side In this position, it is drawn along and very slightly across the line of cut, almost in a stropping fashion The blade must be very sharp If the knife is used in this manner, the tissues rise into the wound and the operator has a fraction of a second to see and avoid important structures, because they roll up into view under the sloping blade, just before they stand in danger of being divided The time afforded is sufficient for the pressure of the knife to be momentarily released It passes on its way, leaving the structure exposed and undamaged, or sinking back safely If one's knowledge of anatomical detail is sound, the pressure on the blade is actually being eased as it approaches an important structure This is an additional safeguard, supplemented often by recognition of a deep guide, such as the sternomastoid branch of the occipital artery when approaching the spinal accessory nerve in the neck Again, in making a longitudinal incision across the bend of the elbow, the easing-up of pressure on the knife at the sites of the superficial veins prevents their division as they come up into view under the sloping and slight angling of the blade

Rightly employed, the knife is a knife and dissector in one, the safest of instruments and one which does the least damage to the tissues Merely to incise tissues is not to dissect them To cut them apart and display them to view requires that the instrument must be used in a particular manner With practice, the blade may be tilted over to one side or the other, as may be convenient, in alternate pronation and supination of the surgeon's forearm and in an upward or downward direction The point of the knife is not to be used In freeing the tonsillar lymph-node, for example, it is unsafe, as the deeper part of the dissection is reached, to complete the final separation by a scissors cut, if this is done, the thin-walled jugular and common facial veins are kinked and cut Nor is it safe, at this stage, to use blunt dissection for this purpose The correct procedure is to continue with the knife dissection to the very end, keeping the edge against the gland In the final stages of a dissection especially, blunt and blind methods should be avoided Trouble is not unusual in the very moment of completing operations for these reasons, and sometimes because the operator fails to leave off when the real purpose of the operation has been completed

If the parts have been disturbed by trauma or by scar, normal anatomy above and below the lesion should be exposed first, so that the operator can proceed from the normal to the abnormal Important structures in the vicinity should be deliberately exposed and gently retracted before going on It is a safe rule in surgery to expose what one wishes to protect In a fractured humerus, the radial nerve is sought and retracted before dealing with the fracture In the case of the peripheral spinal nerves, it is necessary to know the sites of origin of the branches and from which side of the nerve they arise, so that the knife may free the trunk by mobilising first the side of the nerve from which they do not arise For example, in the case of the median nerve at and below the elbow, all the branches save one arise high up in the forearm, mainly on the posteromedial side of the main trunk If, therefore, the knife is passed up along this side of the nerve all these branches will be severed at a stroke The same remarks apply to the blood-vessels Like the nerves, they are best freed mainly from above downwards and on the appropriate side To facilitate dissection, toothed forceps of comfortable spring should be held in the left hand In the more difficult limb dissections, three assistants are best, one to act as first assistant, the second to retract, and the third to hold and steady the limb

If reliance is placed on a good knife, used correctly, there should be no great need to resort to blunt dissection in the surgery of the neck and limbs If used to excess it prolongs the operation needlessly and predisposes to shock Inadequate incisions, scratchy work with the point of the knife, and heavy retraction all devitalise the tissues and predispose to infection, hæmatomata, œdema and pain A rigid non-touch technique may contribute to the undue length of an operation Unhurried speed, especially in war surgery, is of great importance, as are gentleness and sound judgment in not attempting too much at one sitting The best treatment of postoperative shock is prevention This applies particularly to children I have known a spinal bone-graft take nearly 3 hours to perform, with fatal results to the patient It should take 40–60 minutes

BONE WORK

In open reduction of fractures the difficulty often lies not in the actual reduction but in maintaining it until a reliable means of retention has been applied To avoid rigid internal fixation in a fracture of the shaft of the humerus, for example, two narrow strips of aluminium or other metal, about 2 in. broad by 10 in. long, are sterilised, as soon as the fracture has been reduced, and perhaps sutured by a stitch of catgut or kangaroo tendon, the metal strips are padded with sterile gauze. They are bandaged lightly but firmly, with a sterile bandage, to the posterior and medial aspects of the upper arm, leaving the wound uncovered. Their efficiency is tested while the fracture is still visible. The wound is closed and the limb and splints put up in a plaster spica. I am indebted to the late Mr. Naughton Dunn for this advice, and have employed it satisfactorily since. If one of the fragments is difficult to control, it may be steadied by the insertion of a pin, which is incorporated in the plaster.

In using an osteotome, gouge or chisel, the tap of the mallet is to be taken up and resisted by the grip of the hand holding the instrument, lest it should suddenly penetrate too deeply. The tap of the mallet and the shock-absorbing, buffer-like opposition offered by the other hand must be so coordinated that the instrument is not only checked but also made to recoil. It must not be allowed to travel on unchecked after the effect of the tap has been achieved. The markings on Macewen's osteotome are an additional safeguard. In cutting away bone on a sloping or curved surface the instrument must be laid accurately, so as to follow the camber with precision. This prevents the instrument, struck and controlled as above, *from slipping off and injuring other* structures. These rules should be strictly observed, they are essential for safety in difficult situations. In performing osteotomy, additional protection is given by the insertion of a curved bone elevator passed round the bone subperiosteally, opposite the site of the proposed division. It is of service, also, to make a series of drill-holes, ½ in. apart, through the bone, in the line chosen for the osteotomy. Only relatively light taps of the mallet are then required and the chances of splintering or of fracturing the bone in the wrong place greatly lessened, if the bone is abnormal at the site of division this is particularly important. Instead of a linear osteotomy it is often best to perform it in the form of a V, upright or inverted, because more accurate control of the position can thus be assured. In some instances this method can obviate the use of a plate—for example, in derotational osteotomy for the relief of congenital dislocation of the hip. It is useful, too, in the correction of a malunited fracture, because correction in both planes and of rotation may thus be obtained. If there is doubt whether position can be controlled after osteotomy, drill-holes for the passage of a suture should first be made on either side of the site for division of the bone. This applies in section of the clavicle in an extensive brachial plexus dissection.

WOUND CLOSURE

In stitching up wounds of the limbs, subcutaneous suturing is not often necessary. The interrupted skin sutures, put in *not too near one another, include the* deep fascia and subcutaneous tissues. This diminishes the likelihood of infection and helps to prevent œdema, tension and pain, because it allows of drainage between the stitches. If the wound is to be kept covered for long beneath a plaster casing, it is advantageous to apply bipp to the closed incision and skin round it. Bipp is a good sentinel antiseptic and prevents maceration of the skin from discharges. In closing wounds in which there is tension, the stitches should begin at the ends. To prevent cutting out of the stitches, they may be first threaded through 1 in. strips of fine rubber tubing. If one of the flaps is short and relatively fixed, it is a good plan to swing up the more redundant flap to the best position for covering the area. An incision is then made at a right angle into the fixed flap at this point, so lengthening it. This is especially useful in closing the wound after radical excision of the breast and avoids the need for skin-grafting. Opinions vary as to the use of tourniquets. I often use a tourniquet in operations on the lower limb, but prefer not to use it on the upper limb as a rule. If it is employed in the upper limb, a broad Martin's bandage applied over a towel is safe, but it should be discarded in a few minutes, once the operation has got under way.

I am indebted to Sir Harold Stiles for most of the points, I learnt them as his assistant.

POSTVACCINAL ERUPTIONS

E. BLOCH, M.B. GLASG., D.P.H.
DIVISIONAL MEDICAL OFFICER, PUBLIC HEALTH DEPARTMENT, GLASGOW

TOWARDS the end of May, 1942, a previously unrecognised case of oriental smallpox arrived in Glasgow on board ship and was removed to hospital. There ensued in and around Glasgow during the following two months 9 cases directly connected with the ship, 20 shore cases apparently unconnected with the ship or with each other and 4 cases secondary to this latter group. Two of the ship cases and 6 of the others died. Wide measures of surveillance and vaccination of contacts had been practised from the outset. In addition, a mass vaccination campaign was launched at the end of June comprising the establishment of 25 public vaccination stations and the regular issue on a large scale of lymph to medical practitioners. Thanks to the enlightened response of the public and to the cooperation of doctors and the press, about half a million vaccinations were performed during July.

As one result a large number of regional or generalised vaccination rashes appeared among both children and adults. There was evidence that many cases, where the eruption was sparse or fleeting or the degree of illness negligible, must have eluded medical observation. In several other instances patients consulted a doctor but were not referred for further medical review. Records are available, however, of 123 regional or generalised postvaccinal eruptions examined at the invitation of doctors in the city by the central medical staff of the Public Health Department. The cases so examined are regarded as forming a substantial proportion of the probable total number of the more extensive, severe or clinically perplexing cases. An analysis of the records now seems desirable because the cases included a death and also because of the difficulties raised in diagnosis and administration.

ANALYSIS OF CASES

Clinical classification.—The clinical appearances of the eruptions, and numbers of cases showing them, were as follows:

Papular	
Papules	5
Maculopapules	2
Urticarial and erythematous	
Papular urticaria	37
Erythema multiforme	20
Morbilliform erythema	16
Scarlatiniform erythema	6
Roseola	5
Urticaria	5
Erythema iris	4
Nummular erythema	2
Erythema	2
Red urticaria	1
Purpuric	
Petechiæ	2
Pustular	
Bullous impetigo	9
Folliculitis	4
Pustular erythema	1
Exfoliative dermatitis	1
Eczematoid	
Papular eczema	1

The names are in some instances rather arbitrary and not rigidly definable but each will convey a range of appearances. Combining ætiological with clinical classification, Stelwagon (1916) grouped the urticarial or erythematous and the purpuric rashes together as due to pure vaccine inoculation, and impetigo and furunculosis as due to mixed inoculation introduced at the time of vaccination or subsequently. He also recorded cases of pemphigus, a few serious, but placed the pemphigoid eruptions in a group of sequelæ of vaccination. His list of sequelæ included also eczema, urticaria and furunculosis. The list above shows most of our cases in the toxic group, 2 of them purpuric, and 15 in the infective group when the fatal exfoliative case is included. Impetigo was present in this case. There was also other evidence of infection by staphylococci, and infantile exfoliative dermatitis, like acute pemphigus, has been regarded in some cases as a variant of impetigo contagiosa. One eruption fell by reason of its interval into the category of late sequelæ—the papular eczema which erupted 7 weeks after vaccination, to which, however, it was clearly related; and there was one reported recurrence of papular urticaria.

Vaccinal state.—All the cases had been positively vaccinated and nearly all showed a well-marked local reaction. Only 22 persons had been successfully vaccinated *previously*. This small proportion contrasts with the percentage of Glasgow births annually vaccinated. The M.O.H. annual report for 1938, p. 84, reported that this figure has remained at 40% or over. It ears despite its having fallen by half since the beginning f the century All the cases were successfully vaccin-ted on the present occasion at the first attempt although t was alleged that 0 had failed to take in infancy (includ-ng 1 case unsuccessfully attempted twice in infancy and cases thrice attempted)

Age and sex distribution —The age-distribution was s shown

Age	0–1	1–4	5–9	10–14	15–19	20–29	30–39	40–49	50
Cases	8	23	13	18	8	14	6	2	1

Thus 75% of the cases were under 15 years of age The youngest patient was aged 6 weeks at vaccination, the oldest 50 years Only 12 of the cases were males Females preponderated, though to a lesser extent than among adults, even among the children, numbering 59 of the 92 cases under 15 years

Interval between vaccination and eruption —The number of days between vaccination and the appearance of the regional or generalised eruption was as follows

Days	Cases	Days	Cases	Days	Cases
2	1	8	26	18	1
3	2	9	26	19	2
4	1	10	19	22	1
5	4	11	13	24	2
		12	2		
6	5	13	2	27	1
7	13	17	1	49	1

The interval 7–11 days therefore covered the great majority of the cases Excluding the late sequela case the average interval was 8 4 days for primary vaccinations and 0 2 days for revaccinations One would have expected the shorter interval in the revaccination group since their local reactions mature earlier but the number of our revaccinations is small

DIAGNOSIS

The diagnostic difficulties were at first considerable, but soon both practitioners (who then referred fewer cases for consultation) and departmental officers attained confidence in separating postvaccinal eruptions from variola Except pruritus, symptoms were of little help because they could be ascribed to the positive vaccination. The chief grounds for excluding variola came to be the regional limitation or grossly asymmetric distribution, a report or evidence of itching, and the character of the lesions themselves

Several punctate, morbilliform and diffuse *erythemata* were restricted to the trunk or part of the trunk, others to the legs, to the arms and legs or to the forearms and legs, only a few were generalised In the *roseola* cases the lesions were discrete and centrifugal but included some irregularly shaped patches and were flat and fugacious One of the many profuse cases of *erythema multiforme*, an adult who remained off work for a month, had numerous facial and even a few palatal lesions, but the skin lesions as in all the cases so classified were pleomorphic *Nummular erythema* is described by Ricketts and Byles (1908) in their differential diagnosis of variola, one of the present cases had chiefly a long glove distribution, in the later case the trunk was also affected The boy with *red urticaria* was severely ill and displayed meningismus, but his extensive eruption lacked particulate elements *Impetigo bullosa* involved the vaccinated arm but in each case only one or two other regions, the individual lesions suggested vaccinia rather than variola, and there was usually a typical impetiginous scab somewhere In the *folliculitis* group the vesicopustules and pustules, which seemed related to hair follicles but fell short of furunculosis, were small, rapidly evolving and scanty though widely dispersed In the *pustular erythema* case the pustules were irregularly shaped, of various sizes, thin walled and very superficial

The present series is notable for the number of cases of *papular urticaria* Frequently this was centrifugal, favoured the extensor surfaces of the limbs and showed in its early stages pink areolæ round the pinhead sized papules, some of which, too, showed crusting or suggested vesiculation and even umbilication In all the lichen urticatus cases, however, there was a report or evidence of itching and many showed regional urticarial wheals The less striking discrete *papular* eruptions are of interest because casual observation suggested that many unreported rashes were of this kind, being often recognised as harmless spots or pimples Some were widely distributed but most were scanty Some began to subside within 24 hours, in other cases papules persisted for several days Four of the reported cases were adults The two *maculopapular* rashes were widespread and one child showed a circumvaccinal ring of macules with slight vesiculation of some other lesions, but the general distribution and evolution were not suspicious

Eruptions of the kinds listed above affecting several unvaccinated persons were also reviewed during the same period Papular urticarial rashes were also seen in some children suffering from scarlet fever, chicken-pox or scabies, a few of these children (excluded from this report) had positive vaccinations There were also referred to us a considerable number of other rashes, such as those of chicken pox, measles, acne, scabies, drug eruption, flea-infestation, and sudamina, and, in unvaccinated persons, of staphylococcal dermatitis, syphilis, erythema nodosum and herpes zoster Looking back on the types hardest to diagnose, one can now say that it eventually became less difficult to exclude variola in postvaccinal eruptions than in some cases of early measles or more notably of atypical chicken-pox, despite the probability that in ordinary times even the chicken-pox cases would have raised little doubt Nevertheless there continued to occur postvaccinal cases strongly suspected to be papular urticaria but so simulating early variola that smallpox hospital isolation and observation were preferred to observation, even by more than one medical officer, in the patient's home

ADMINISTRATION

Six cases—erythema iris 4, red urticaria 1, folliculitis 1—were sent to a fever hospital on account of the degree of illness In the girl with folliculitis its appearance was associated with the onset of petit mal No fewer than 16 cases were removed to the smallpox hospital—papular urticaria 8, urticaria 3, roseola 2, and one each of erythema multiforme, nummular erythema and folliculitis Although these cases were removed to the smallpox hospital full administrative action was usually withheld pending an opinion from the hospital Some eruptions began to fade or abort within 24 hours, others within 2–3 days, while a few persisted longer but declared themselves by the manner of their development Meanwhile only familial contacts were vaccinated and these were not removed to the reception house; and no disinfection was performed Often, however, the neighbours would themselves decide to visit a vaccination station

LYMPH AND VACCINATION TECHNIQUE

Ricketts and Byles attributed generalised erythemata to circulation in the blood-stream of the secondary products of inflammation absorbed from the vaccine pustule, they regarded even the particulate eruptions as toxæmic and not as implying generalisation of the specific virus Chalke (1031) reported 14 eruptions appearing usually on the eleventh day in 14 primarily vaccinated children in a six-months series of 1000 vaccinations In a general review he agreed with Ricketts and Byles that many vaccination rashes are accidental and toxic, but held that others are due to idiosyncrasy and are allied to serum rashes The latter are likewise reported as frequently morbilliform, scarlatiniform, urticarial or erythematous though differing from postvaccinal eruptions in being often associated with special symptoms or with sensitisation by previous injections He could not find evidence pointing to any particular batch of lymph In the present series there was no incrimination of any particular lymph establishment or batch, for several batches of Government and of various commercial lymphs had been used for the cases

The Ministry of Health Committee on Vaccination (1928, pp 260, 291) reported that strapping used in dressing the wound was responsible for the unilateral scarlatiniform or urticarial eruptions encountered 2–8 days after vaccination in nearly 74% of a group of men, although apart from this group they also reported eruptions in men on the ninth and tenth days (papulovesicular, erythematous, purpuric and a serum type) In the present series unilateral eruptions were few As regards the amount of scarification, many vaccinators and doubtless many methods were involved, but in a great number of cases the scarification was of the moderate extent officially prescribed for the vaccination stations—three strokes ⅜ in. long and ⅛ in. apart Although in almost all our cases the local reaction was well-marked, severe reactions due to extensive scarification were noted only in 2 cases of morbilliform erythema, 2 of punctate erythema, 1 of papular urticaria, 1 of erythema multiforme and also in most of the cases of impetigo bullosa In one of the punctate cases the rash appeared 22 days after the vaccination which was still very septic, there was circumoral pallor (a feature also of several of the papular urticarial cases) and the case was very like scarlatina except that the throat was practically normal in appearance

CLEANLINESS FAMILIAL INCIDENCE PRE-EXISTING SKIN DISEASE

Many of the houses in which our cases occurred, including some of the infective group, were quite clean Although most or all of the familial contacts of our cases had also been vaccinated, in only two families did an eruption affect more than one member—one family yielded a maculopapular eruption and a younger case of erythema multiforme while in another family a case of papular urticaria was associated with an infantile morbilliform erythema The hospitalised case of nummular erythema—a direct contact of smallpox—was the elder sister of a boy aged 6 who sickened of mild encephalitis 14 days after positive primary vaccination or 11 days after a positive revaccination

Pre-existing skin disease was rarely found or alleged, in a few cases previous attacks of heat spots or " hives " were alleged Conversely, in one adult case of papular urticaria removed as suspected variola and retained for 24 days the eruption recurred the day after dismissal

NOTABLE ERUPTIONS

Petechial group —The two patients were aged 6 and 10 years and the eruptions appeared 8 and 9 days respectively after vaccination The spots were on the trunk One of the children was sharply ill with fever and headache

Pustular group —Excluding the exfoliative case, the ages of these cases ranged from 8 months to 30 years, and the intervals from 7 to 11 days except in one case of impetigo bullosa appearing 24 days after vaccination. Impetigo bullosa was the class of postvaccinal eruption in which the clinical diagnosis of generalised vaccinia demanded the closest consideration, owing to the similarity of the lesions to a vaccine pustule and to the presence in most of the cases of a cluster of the bullæ round the vaccination pustule However, it was preferred to regard these cases, as Stelwagon regarded such cases, as probably impetigo because the distribution was regional (the vaccinated arm and in every case one or two other regions such as another limb, the face or an area on the trunk), because most of the cases also showed impetiginous scabbing, and because the bullæ were often at an earlier stage of development than the vaccination pustule This last feature was most obvious in the case occurring 24 days after the vaccination which had then almost healed, and furnishes an argument also against a diagnosis of multiple auto-inoculations Auto-inoculations were often diagnosed in Glasgow but the pustules were either single or very few

Generalised vaccinia —Although many eruptions remained unreported in Glasgow, the circumstances were on the whole very favourable for reporting Even when allowance is made for these favourable circumstances, the incidence of non-specific postvaccinal eruptions is found to be much greater than that recorded in various countries for generalised vaccinia—namely, one case of generalised vaccinia in about every 10,000, 20,000, 100,000 or even a million vaccinations It is noteworthy nevertheless that no Glasgow vaccination rash was regarded as generalised vaccinia

Chalke goes so far as to say that it is probably always due to auto-inoculations He adds that the number and situation of the secondary lesions will depend on the number and site of the auto-inoculations, and that clues to the diagnosis will be provided by the absence of personal cleanliness and in some cases by the presence of an old skin eruption or of recent septic wounds Van Rooyen and Rhodes (1940) likewise conclude that the majority of generalised vaccinal eruptions are due to accidental infection caused by auto-inoculations and also note the occurrence of generalised vaccinia on areas of burns and dermatitis The subjects of clinical descriptions of hæmatogenous generalised vaccinia have doubtless occasionally been varioloid, which in any event it is impossible to exclude clinically

Therefore in figures however small of generalised vaccinia there arise possibilities of confusion, partly owing to the inclusion of non-specific vaccination rashes and of varioloid, partly because recognised cases of multiple auto-inoculation may or may not be included and also because multiple auto-inoculations can be simulated by impetigo bullosa Throughout the imported Glasgow smallpox outbreak and the consequent vaccination campaign the cases most strongly suggesting true generalised vaccinia on the first examination were 4 of the ship's crew erupting 9–13 days after well-marked primary vaccination and one previously well-vaccinated passenger erupting 11 days after successful vaccination These cases were admitted to the smallpox hospital where the duration and degree of illness caused them to be regarded as varioloid

Fatal infantile exfoliative dermatitis —A healthy breast-fed infant was vaccinated when aged 8 weeks together with his mother and a brother at a vaccination station to which he was not brought back On the tenth day after vaccination he was seen moribund by a department medical officer in a general hospital reception department where the child died On the fifth day he had become irritable, had refused feeds and had vomited On the sixth day his skin was pink and there were a few red spots on his back and buttocks During the next few days he slept better but still refused feeds, and a few red spots appeared on the face Boracic powdering of the vaccine pustule, which reached the size of a shilling, was practised On the evening of the tenth day he began to grunt, roll his eyes up and make constant attempts to vomit, he died three hours later Necropsy was performed next day by Dr T. Anderson, Knightswood Hospital, who reported

> " There were numerous denuded areas on the face measuring 1–3 cm in diameter with raw skin underlying The whole of the left upper arm from the shoulder to the elbow and stretching round to the axilla was completely denuded of skin with what appeared to be a fairly healthy vaccination in the centre The buttocks were inflamed and there was a coarse desquamation of the front of the legs On the back of the legs, however, there had been what appeared to be an exfoliative dermatitis, the whole skin lifting on pressure There was some recent crusting of the back of the scalp which was very suggestive of impetigo The heart, lungs, spleen, liver and kidneys were normal There was no suprarenal hæmorrhage The bowel was empty but otherwise appeared to be normal The skull was opened and the brain appeared to be slightly œdematous but there was no flattening of convolutions nor was there any pressure cone A section of the brain showed a normal appearance "

Dr Anderson further reported after bacteriological investigation·

> " Cultures taken from the site of the vaccinal lesion show a profuse growth of various organisms so that it is impossible to incriminate any particular one The cultures from the heart blood and from the spleen have yielded a *Staphylococcus aureus* which is hæmolytic and exhibits a positive coagulase test "

Sequelæ of vaccination —A healthy child vaccinated at the age of 3 months erupted 7 weeks later with regional papular eczema of the type that has been called lichen simplex, most profuse in the axilla of the vaccinated arm but extending also round the whole brachium and across the upper part of the chest anteriorly and posteriorly to the opposite shoulder Though the majority of the elements were lichenoid there were also scanty crops of larger papules which vesiculated apically but soon lost their areola and dried up with a tiny scab The vaccinal area was of moderate size and healed but tumid and inflamed Seen a week after the onset she was in good general condition but cried continuously

This regional eruption was topically related to vaccination and was reported to us on account of its interest Accidental observations revealed unreported sequelæ in the form of chronic manifestations of originally postvaccinal urticaria, and we were unlikely to be asked to see late generalised rashes not simulating any infectious disease and not obviously connected with vaccination The following late eruptions, however, have recently been reported · papular urticaria (7 weeks after vaccination), generalised bullous impetigo (9 weeks), in which the vaccinal area was heavily crusted and had failed to heal, and 2 cases of erythema marginatum (8 weeks, 11 weeks) In both the marginate cases some lesions showed urticarial characteristics The earlier case was an adult, some of whose lesions persisted for a month while other areas desquamated

SUMMARY

After about 500,000 vaccinations in the summer of 1942 in Glasgow, 123 regional or generalised postvaccinal rashes were reported Many cases, especially those of slight degree, eluded formal report The majority appeared 7–11 days after well-marked positive primary vaccination of children A regional papular eczema erupted 7 weeks after vaccination of an infant Diagnostic difficulty was at first considerable but soon diminished except in some cases of papular urticaria Ætiological findings were negative Of 98 erythematous or urticarial eruptions 37 were papular urticaria and 20 pleomorphic types of erythema multiforme Though regarded as impetigo bullosa a group of cases simulated multiple auto-inoculations No case was classified as generalised vaccinia A previously healthy breast-fed boy positively vaccinated when aged 8 weeks at a vaccination station died 10 days later of exfoliative dermatitis on the sixth day of illness or fifth day of the complicating eruption, the complicating disease was regarded as staphylococcal

This paper is partly based on material supplied by my colleagues in the Public Health Department

EFFECT OF
SULPHONAMIDE PREPARATIONS ON EXPERIMENTAL INFECTED WOUNDS

FRANK HAWKING, D M OXFD
(*National Institute for Medical Research, Hampstead*)

BATTLE conditions in modern warfare often make orthodox surgical treatment impossible In these circumstances it has been suggested[1] that wounds should be filled with a sulphonamide paste without more than superficial cleansing, and covered by an occlusive dressing which would remain in position for several days The purpose of the present paper is to describe an investigation of the therapeutic activity of various preparations of sulphonamides in these circumstances, this is the conclusion of a wider study of the whole subject, and other aspects—the effect of these preparations on the rate of absorption of the sulphonamides and their histological effects on the tissues—have been described elsewhere (Fuller, Hawking and Partridge 1942, Hawking 1942) At the end of the paper Gardham's proposal will be evaluated in the light of the whole experimental evidence which has been accumulated

TECHNIQUE

Rabbits weighing about 1 5 kg were used The animal was anæsthetised with ether, and a small incision was made through the skin proximal and lateral to the popliteal space A small pair of scissors was inserted and the hamstring muscles were clipped in many places, extending up to the ischium and great trochanter Through a pipette, 1 c cm of a 12 hour culture of hæmolytic streptococcus (strain Pion) was introduced into the wound Strain Pion is very virulent for rabbits and is also quite sensitive to sulphanilamide The number of MLD contained in this inoculum was not estimated exactly, but, since animals died with equal rapidity when dilutions of 1/1000 and 1/10,000 were used, it is considered that considerably more than 10,000 MLD of the streptococcus was employed A standard amount of the preparation, equal to 0 6 g sulphonamide, was inserted in the same locality by means of a syringe and a long blunt needle The opening of the wound was closed by a purse string suture Animals which survived were observed for 30 days, after which they were killed, and the wounds were examined histologically In animals which died in less than 30 days, a culture was made from the heart blood, and in all cases streptococci were discovered Under these circumstances, control untreated animals died in about 1–5 days (usually in 2 days) with septicæmia, peritonitis, &c (see below)

In this technique the original wound was designed to resemble the type of lesion produced by a high velocity missile—a small puncture through the skin, with extensive laceration of the underlying muscles The subsequent infection and treatment were both much more intense than those of a natural wound would be Although the conditions may appear somewhat artificial, this arbitrary standardised procedure makes possible a more accurate comparison between the different preparations than would be possible with natural, wounds Experiments of this kind give information concerning the *comparative* value of one preparation contrasted with another, rather than concerning the *absolute* value of such treatment in actual human wounds Thus, although wounds infected with organisms less sensitive than strain Pion would respond less readily to sulphonamides, the relative efficacy of the different preparations would, nevertheless, be the same as that found below

The preparations employed in this work were as follows

Hypoloid sulphanilamide a Burroughs Wellcome preparation containing a 15% solution of the compound in combination as sulphanilamide lactoside sodium formaldehyde sulphoxylate (LSF)

Preparation J (aqueous) sulphanilamide 30, calcium citrate 0 21, sodium alginate 0 21, spermaceti 0 06, water to 100

Preparation K (aqueous) sulphanilamide 30, beeswax, cetyl alcohol and oleic acid each 1 4, triethanolamine 0 35, water to 100

Preparation L (aqueous) sulphanilamide 30, triethanolamine 0 33, stearic acid, white beeswax and wool fat each 1 41, water to 100

Preparation B (oil in water emulsion) sulphanilamide 30, liquid paraffin 28 5, cetyl alcohol 1 4, stearic acid 2 0, triethanolamine 1 0, arachis oil 1 5, water to 100

Preparation C (oil in water emulsion) sulphanilamide 30, beeswax 0 7, cod liver oil 49, oleic acid 3 6, sodium hydroxide 0 5, water to 100

Preparation D (oil) sulphanilamide 30, beeswax 10, cod liver oil 60

Microcrystalline sulphathiazole a 20% suspension of microcrystals in saline (Chambers et al 1942)

Microcrystalline sulphadiazine a similar suspension, 8%

Further details about these preparations are given by Fuller, Hawking and Partridge (1942)

RESULTS

In the first series of infections the sulphonamide preparation was applied immediately after the infection The proportion of animals which survived is shown in table I, and the rate of absorption of sulphonamide (as judged by the average urinary excretion) in table II The relative rates of absorption and excretion are concisely illustrated by a comparison of the percentage *excretion on the first day* with that on the combined fourth and fifth days, more detailed information is given elsewhere (Fuller, Hawking and Partridge 1942) Among the four animals treated with sulphanilamide

TABLE I—NUMBER OF ANIMALS WHICH SURVIVED WHEN TREATMENT WAS APPLIED IMMEDIATELY AFTER THE INFECTION

Treatment	Proportion of animals which survived	Average days of life in animals which died
Controls	0/14	2 3 (1–5)

LSF, none survived and life was only slightly prolonged, among the animals treated with the two aqueous preparations of sulphanilamide, J and K, only 2 out of 10 survived These three preparations are quickly absorbed and excreted, and presumably the sulphanilamide is removed from the wound so quickly that its bacteriostatic action is exhausted before the defence mechanisms of the body have been sufficiently mobilised With the oil-in-water emulsions, B and C, the sulphanilamide is also rapidly absorbed and excreted, although other work has shown that when the surface volume ratio is not too great the presence of this emulsion does delay absorption to a moderate extent, 5 out of 10 rabbits survived. With the oily preparation D, absorption is more delayed and the therapeutic results are improved, 7 out of 10 surviving Including results obtained with normal rabbits, described elsewhere, it is found that, according to their rates of absorption, the preparations should be arranged in the following order

Sulphanilamide LSF (most rapid)
Aqueous preparations (J & K)
Oil in-water emulsions (B & C)
Oily preparation D (least rapid)

According to the therapeutic effectiveness, the compounds should be ranged in the reverse order Admittedly the numbers of the rabbits are small, but nevertheless the correlation between these two aspects is impressive Since the action of sulphonamides is bacteriostatic rather than bactericidal, this is what would have been expected on theoretical grounds—that any factor which delays the absorption of sulphanilamide, and thus prolongs its presence in a wound, thereby increases its therapeutic efficacy In the groups treated with microcrystalline sulphathiazole or sulphadiazine, all (10/10), or all but one (4/5) of the animals survived, the superiority of these preparations may be due partly to their slower rates of absorption and partly to their higher bacteriostatic activities

TABLE III—EFFECT OF DELAYING THE TREATMENT

Preparation	Interval before treatment (hr)	Proportion of animals which survived	Days of life in animals which died
Controls	—	0/3	1, 2, 2
Sulphathiazole	0 6 17	4/4 2/4 3/4	13, 13 20
Aqueous sulphanilamide K	0 6	1/2 0/2	6 8, 12

During this work a comparison was made between the effect of treatment by local application and treatment by systemic administration Five rabbits were given the standard dose (0 6 g) of sulphathiazole by subcutaneous injection instead of by insertion into the wound All survived and consequently in this series no evidence was obtained as to the relative value of the two methods However, this comparison has now been studied by so many workers, and the value of local application is now so widely recognised, that additional work was considered unnecessary

TABLE IV—EFFECT OF INFECTING THE WOUND 24 HOURS AFTER INSERTION OF THE SULPHONAMIDE PREPARATION

Preparation	Proportion of animals which survived	Days of life of animals which died
Controls	1/4	4, 4, 6
Aqueous K	3/4	6
Oil in water emulsion B	2/4	3 6
Sulphathiazole suspension	4/4	—

Effect of delay in treatment—In another series of animals a delay of 6 or 17 hours was allowed to occur before the sulphonamide compound was inserted The results are shown in table III The well-known effect is observed, that if treatment is delayed the therapeutic results are impaired, although in this case the impairment was not so great as might have been expected As this aspect has also been much studied by others no further animals were sacrificed merely to emphasise this point

Duration of bacteriostatic action in the wound—A series of experiments was studied in which the wound was inflicted and the standard amount of sulphonamide (0 6 g) inserted, and 24 hours later an attempt was made to infect the wound by inserting 0 5 c cm of a 1/10 dilution of a 12-hour culture of streptococcus The results (table IV) show that a certain degree of bacteriostatic action is still present 24 hours after treatment The number of experiments is too small for a detailed comparison to be made, but no more animals were used since a more accurate study of the persistence of sulphonamides in wounds had been made by chemical methods (Fuller, Hawking and Partridge 1942)

HISTOLOGY

The effects of these preparations on the histology of uninfected wounds has been described elsewhere (Hawking 1942), here the description will be limited to the changes in the infected wounds The appearances are summarised in table V

Untreated wounds (*a*) *Immediate*—In animals which died within 2–4 days the wound usually contained a small amount of transparent sticky fluid, pus was practically never seen

Microscopically the lesions were characterised by necrosis of the muscle and other tissues, and by exudation of fibrinous fluid Leucocytes were few and they quickly died and disintegrated (*b*) *Delayed* —In animals which were kept alive by the subcutaneous administration of sulphathiazole (table I), and which were killed after 39–88 days, there was a variable amount of semifluid white or yellow caseous material enclosed in a cyst wall of variable thickness, drainage of the wounds had been prevented by suturing the mouth and the caseous material was derived from the necrotic tissue and inflammatory exudate Adjacent muscles were atrophied and fibrosed to a variable extent Microscopically there was much caseous material consisting of necrotic debris and broken portions of muscle fibres This was surrounded by much collagenous fibrous and granulation tissue in which were embedded necrotic muscle fibres, often calcified and often surrounded by giant cells, clusters and strands of foam cells, and small abscesses

TABLE V—SUMMARISING THE HISTOLOGICAL APPEARANCES OF INFECTED WOUNDS TREATED WITH THE VARIOUS PREPARATIONS

Treatment	Histological reaction	
	Immediate	Delayed
Controls	Exudate of fibrinous fluid with few leucocytes necrosis of muscle leucocytes and connective tissue	Encystment of caseous debris by fibrous tissue Calcification of necrotic muscles fibres and giant cell reaction to them Phagocytes loaded with fat globules Atrophy and fibrosis of muscle
Aqueous K	Like controls, but more leucocytes commencing calcification of muscle fibres, presence of paste	Like controls (1 animal)
Aqueous J	Like K	Like controls plus giant cells and masses of alginate in some animals
Oil in-water emulsion B (paraffin)	Like K, but oil globules more conspicuous	Like controls, plus "paraffinomatous" tissue in walls of cyst
Cod liver oil preparations C & D	Like K	Like controls, but more fibrosis and an intense giant cell reaction to the cod liver oil
Microcrystalline sulphathiazole and sulphadiazine	No animals died	Like controls Caseous material and fibrosis minimal

Preparation K (aqueous) —In rabbits dying after 4–8 days, the appearance was much the same as that of the controls, except that the wound often contained some whitish fluid (base of preparation), sulphanilamide had all been absorbed Microscopically the remains of the paste were seen There was an exudate of fibrin, and the cells (mostly mononuclears) were much more numerous than in untreated wounds, the greater part of the cells were degenerate, the cytoplasm occasionally contained numerous fine vacuoles, but there did not seem to be general blockage of the phagocytes by oil globules The necrosis of muscle was similar to that of the controls, by the 4th day and onwards some of the necrotic fibres had undergone calcification Also by the 4th day granulation tissue had been formed, although it did not yet contain new collagen In one rabbit killed after 37 days, the wound resembled the controls

Preparation J (aqueous) —In rabbits which died after 6–8 days the wound contained a little white creamy material. Microscopically the appearances were similar to those with preparation K, except that the paste was usually inconspicuous In 3 rabbits which were killed after 31–39 days, white caseous material was found enclosed in thin-walled cysts Microscopically these resembled the controls, except that in one animal masses of hyaline material (alginate) were embedded in the fibrous tissue, and giant cells were present In 3 rabbits, 33 days after this preparation had been applied to an uninfected surface wound, there was much fibrosis and a few giant cells, in one case there were many small masses of alginate embedded in the fibrous tissue under the regenerated epithelium

Preparation B (paraffin oil in water emulsion) —In animals which died in 5–7 days the wound usually contained a thin white cream Microscopically the appearances resembled those with paste K Masses of fine globules of oil were present among the exudate, most of the phagocytic cells were necrotic, but in some cases their cytoplasm was distended with vacuoles, presumably of oil, however, there did not appear to be a general blockage of the phagocytes In animals which died after 31–36 days thin-walled cysts of caseous material were present as in the controls Microscopically the general appearance resembled that of the controls, but the fibrous tissue forming the wall of the cysts contained masses of "paraffinomatous" tissue—i e, globules of paraffin of all sizes from intracellular vacuoles to medium size extracellular masses, embedded in cellular tissue (Hawking 1942) When this preparation was applied to an uninfected surface wound and the animals were killed after 31–60 days, the fibrous tissue underneath the regenerated epithelium usually contained fusiform masses of similar paraffinomatous tissue

Cod liver oil pastes C and D —In 3 rabbits dying after 8–9 days, the wound contained orange pasty material Microscopically the general appearances resembled those with paste K Varying quantities of oil globules were present Giant cells were usually absent, although in one uninfected surface wound, examined after 8 days, they were very numerous In rats with infected wounds treated with these preparations no giant cells were present after 10 days, but they were numerous after 20 days In rabbits killed between 24–71 days after wounding, there was a cyst of brownish (or whitish) caseous material, the walls of the cyst were usually thick, with a rough internal surface, but in a few cases they were thin and smooth Microscopically the general appearance resembled the controls, fibrous tissue and collagen formation being plentiful, in addition there were great numbers of giant cells, which sometimes enclosed hyaline material, either eosinophil or non staining, presumably the remains of the cod liver oil, sometimes the giant cells contained needle shaped spaces (crystals) Masses of endothelioid cells with some lymphocytes were often present around the giant cells Altogether the appearances were similar to those caused by tuberculosis This is the typical histological reaction to cod liver oil (Hawking 1942)

Microcrystalline sulphathiazole —With this preparation no animals died in less than 13 days, at which time (2 rabbits) there was a cavity containing white caseous material Microscopically there was pus and infiltration of the adjacent tissues with mononuclear cells and necrosis of muscle fibres, in one animal the necrotic fibres were calcified and attacked by giant cells and there was much granulation tissue and collagen In animals which were killed after 30–90 days the appearances were similar to those of the untreated controls In about half the cases the caseous material was small in amount and the cyst walls were always thin and smooth The amount of caseous material and of fibrosis present after treatment with this preparation was less than that after any of the other preparations

Microcrystalline sulphadiazine —In 4 animals which were killed after 37–59 days the appearances were indistinguishable from those after treatment with sulphathiazole

DISCUSSION

The original proposal—that when battle conditions render proper surgical treatment impossible wounds should be filled with some semifluid sulphanilamide preparation—may now be considered in the light of the experimental evidence Two questions are to be answered (1) which is the best preparation to use for this purpose, and (2) to what extent and under what circumstances is this method of treatment advisable ?

Fuller, Hawking and Partridge (1942) found that the persistence of a sulphonamide in a wound could be prolonged (*a*) by using an oily base, or, less effectively, by using an oil-in-water emulsion base, provided that the preparation is applied as a compact mass and not as a thin film, or (*b*) by using one of the less soluble sulphonamides—e g, sulphathiazole or the still less soluble sulphapyridine or sulphadiazine In the experiments described here it has been shown that a satisfactory therapeutic result (prevention of streptococcal septicæmia) was obtained most frequently with the microcrystalline preparation of sulphathiazole, and that oily preparations of sulphanilamide were more effective than aqueous ones From the histological studies (Hawking 1942, and above), however, it was found that all oils ultimately excited an injurious reaction of the tissues Cod-liver oil was one of the worst in this respect, linseed oil, lanoline and liquid paraffin were moderately bad, while cotton-seed oil was the least provocative of all From this evidence it is concluded that the best preparation to use would be the microcrystalline preparation of sulphathiazole, since it is the most effective therapeutically and the least injurious histologically, unfortunately supplies of this will not be adequate for a long time The next best preparation would be an aqueous paste such as preparation K, although a small unabsorbable residue would be left in the wound cavity this would be unimportant compared with the amount of fibrinous exudate and necrotic cellular debris which would be present in such circumstances, and the adequate drainage which is required for this necrotic material would also deal with the residue from the paste The slight inferiority of this preparation from the therapeutic aspect would be compensated by its innocuousness from the histological aspect The immediate irritation caused by it may be somewhat diminished by slight modifications of the formula, including the use of stearic acid instead of oleic acid as described above under preparation L (Hawking 1942) If supplies were available, this paste could be further improved by substituting sulphathiazole for part of the sulphanilamide, for the treatment of *large wounds it might be desirable to reduce the total* sulphonamide content to 15% or 10%, so as to avoid using more than 15 g sulphonamide for any one patient Oily preparations of all kinds should be avoided in wounds except where the oil is incorporated in gauze, similar to 'Vaseline' gauze, so that the whole packing can be removed en masse at a later stage leaving no oil in the tissues If oil is left in wounds, it will cause undesirable connective-tissue reactions which may be expected to result in delayed healing, hypertrophic scars and breaking down of the wound Even when it is applied to a raw surface, some of the oil may become embedded in the connective tissue underneath the new epithelium, which is clearly undesirable If an oil is desired for the special circumstances mentioned above, a preparation of cotton-seed oil would seem to be the least harmful—e g, sulphanilamide 10–30%, cotton-seed oil 30%, triethanolamine 1%, stearic acid 2%, cetyl alcohol 1 4%, water to 100%, chlorocresol 0 1–0 2% or some other preservative might be added with advantage to ensure the absence of moulds and of sulphonamide-resistant organisms

The question of the advisability of using any sulphonamide preparation at all in wounds can be settled only by surgical experience under actual battle conditions, but tentative suggestions may be made According to reports from the Middle East Forces (*Army med Direct Bull* 1942, No 11) wounds which have been excised heal much more rapidly than those which have received only sulphanilamide powder and dressing, therefore, when excision is possible, this should be practised On the other hand, the same report states that it has taken twenty-four hours or longer for the majority of the wounded to reach the surgeons In the above experiments it has been shown that streptococcal infections of a wound, which would rapidly cause fatal septicæmia if untreated, may be suppressed by the insertion of a suitable sulphonamide preparation, even if applied after a considerable delay Although these results have been obtained with sulphanilamide-sensitive organisms, such organisms must include a large proportion of those occurring naturally in contaminated wounds, and even on less sensitive pathogens the sulphonamide should exert a restraining, even if not completely inhibitory, influence Consequently it seems that much benefit ought to be received from some simple dressing which might be applied by relatively unskilled hands—e g, by a medical orderly—and which would delay the bacterial growth until the patient reached a place where proper surgical treatment is possible By this means gross sepsis would be diminished and the surgeon would be presented with wounds which were only lightly infected The simple dressing might be (1) sterilised sulphanilamide powder sprinkled from a cellophane envelope, (2) the ordinary field dressing impregnated with sulphanilamide (this would be extremely simple to apply, but would be practical only when new field dressings are to be issued), or (3) a semifluid sulphonamide preparation, squeezed out of a collapsible metal tube The best preparation to use has been indicated above Whatever application is made, it is important that it should not interfere with drainage from the deeper parts of the wound In modern warfare there are many occasions, as in tank battles, commando raids, or torpedoing at sea, when the medical conditions are very primitive and surgical excision of a wound is impossible; in these circumstances the use of simple sulphonamide dressings would be both practical and advantageous

SUMMARY

Using experimental wounds in rabbits, a study has been made of the proposal that when battle conditions make excision of wounds impracticable the wounds should be filled with some semifluid preparation of a sulphonamide, and then covered with an occlusive dressing to prevent exogenous infection

It was found that the persistence of the sulphonamide in a wound could be prolonged by incorporating sulphanilamide in an oily medium or by using a less soluble sulphonamide, such as sulphathiazole or sulphapyridine Therapeutically (i e, prevention of streptococcal septicæmia), the best results of all were obtained with a preparation of sulphathiazole consisting of microcrystals suspended in saline, with sulphanilamide, which is more soluble and more rapidly absorbed, better results were *obtained with oily preparations than with aqueous ones*

Histologically, the presence of an oil in the wounds caused undesirable tissue reactions Of the oils tested, cod-liver oil was especially bad in this respect, liquid paraffin was moderately bad, while cotton-seed oil was the least harmful The best preparation of all was the microcrystalline preparation of sulphathiazole, which was also the most effective therapeutically

Judging by reports from the Middle East Forces, sulphonamide dressing of a wound is inferior to excision Since, however, there are many occasions when exigencies of war render surgical operations impracticable, it is considered that dressing the wounds with a semifluid sulphonamide preparation would be advantageous in restraining bacterial growth until more elaborate treatment was feasible, in these circumstances, the best preparation to use would be the microcrystalline suspension of sulphathiazole, or, failing that, an aqueous preparation of sulphanilamide as described above

Grateful acknowledgements are due to Lieut Colonel A J Gardham for suggesting this research, to British Drug Houses, Ltd, Burroughs Wellcome Ltd, Mr M W Partridge, Ph D, and Dr A J Steigman for the preparations used, and to Mr A T Fuller, Ph D, Mr F J Higginson and Mr R E Leaver for assistance in different aspects of the work

ASSISTANT LECTURER IN ENGINEERING, UNIVERSITY OF MANCHESTER

THE erythrocyte sedimentation test (EST), as commonly used in pulmonary tuberculosis, involves the measurement of the average sedimentation velocity over the first hour The measurements are usually made at room temperatures with *random* volumes of cells In such circumstances anomalous results are often encountered Recent experiments [1 2] have shown that in sedimentation tests with controlled cell-volumes at constant temperature the maximum velocity is largely dependent on the agglutinating power of the plasma, and that this agglutinating power can be demonstrated as a complex function of the plasma-viscosity It therefore seems possible that the plasma-viscosity may serve as a useful clinical index If it were established as such it would have many advantages over the EST Errors due to varying volumes of red cells would be eliminated by

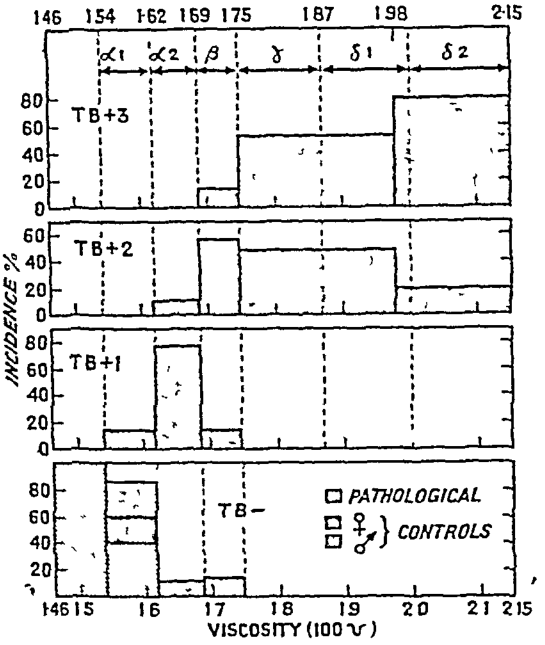
the removal of the cells , and advantage could be taken of a refined viscometric technique giving an accuracy of measurement which is difficult to attain when erythrocytes are involved The measurement of plasma-viscosity, moreover, appears to lead us nearer to the underlying pathological changes in the blood, for viscometry together with protein estimation provides a means of studying the variations in the state of the colloids



Viscometric distribution of Ministry of Health groups in pulmonary tuberculosis TB − TB + 1 etc. Ministry of Health group α1, α2, β etc. suggested six categories in order of increasing toxæmia

The present work covers 76 viscosity measurements, of which 63 were made on tuberculous patients, 1 on a post-operative colostomy case, and 12 on healthy adult controls, 8 male and 4 female

In 13 of the experiments " controlled " sedimentation tests were carried out along with the viscosity measurements , the technique already described[2] was then followed in detail In other cases only 4 c cm of venous blood (with stasis) was used In each case 20% by volume of 3 8% aqueous solution of sodium citrate was accurately pipetted into the blood

The kinematic viscosity coefficient (ν = absolute viscosity divided by density) of the citrated plasma, was measured at 20 0° C in a modified Ostwald viscometer, whose dimensions have been given[2] A varying coefficient, based on experiments with pure liquids, connected ν with the time of flow The normal value of 100ν is of the order of 1 5 sq cm per sec , or 1 5 poises per g per c cm

Clinical correlation —The figure shows the incidence, on a viscometric basis, of the Ministry of Health (M of H) groups in pulmonary tuberculosis Incidence of the control viscosities is also shown, revealing a tendency for the viscosity to be higher in normal women than in normal men

The four M of H groups are sufficient for administrative purposes, the three "TB+" divisions being mainly based on the extent and distribution of the lesions It appeared, however, both possible and desirable from a clinical standpoint to extend the number of gradations to six While radiological findings necessarily provided much of the evidence for grading, the cases were carefully reviewed in the light of such evidence of toxæmia as sanatorium routine can provide When the gradations are increased to six they become more difficult to define precisely The figure helps to show their relation to the M of H groups, and shows where the viscometric scale was divided into six parts (On the evidence so far available the dividing lines appear to coincide in general with critical values of the agglutination and controlled velocities)

The degree of correlation between viscometric and clinical gradings in 53 cases is discussed below On 10 of these cases, viscosity measurements were repeated with the object of comparing the individual viscosity and clinical changes

DISCUSSION

Discrepancy between clinical and viscometric gradings was limited to a difference of one category either way, there being six such categories covering the entire range Four unexplained discrepancies of this magnitude occurred, two in each direction In another case the viscosity was apparently one grade too high, but this was amply explained by a recent pleural effusion In 3 cases the precise clinical grading was doubtful, the viscometric category being either correct or one grade wrong In the 53 single tests, therefore, the agreement between clinical observations and viscosity measurements was between 87% and 92%

In the double tests the most outstanding change recorded was a fall in viscosity of nearly 10% over a period of 14 days coinciding with the beginning of closed suction drainage, and with a well-marked improvement in the patient's condition There is, of course, insufficient evidence to show what is the smallest change in viscosity which can be clinically significant, but in the 10 cases examined all changes in viscosity of 2 5% or more were accompanied by sensible changes in condition

The postoperative colostomy case had a value of 100ν = 1 636, which as the figure shows would have placed him in the α_2 tuberculous category, and on the present evidence is definitely a pathological value

CONCLUSIONS

Estimations of the kinematic viscosity coefficient of the plasma in 63 tuberculous patients, one surgical case, and 12 healthy controls suggest that this measurement gives a good indication of the severity of pulmonary tuberculosis Further insight into the degree of toxæmia might be obtained by carrying out some form of protein analysis as well

We wish to thank Dr W H Grace of Chester Royal Infirmary for providing some of the control samples

Medical Societies

ROYAL SOCIETY OF MEDICINE

At a meeting of the section of Obstetrics and Gynæcology on Oct 16, with Dame LOUISE MCILROY, the president, in the chair, a discussion on

Stillbirth and Neonatal Mortality

was opened by Prof DUGALD BAIRD Taken together these deaths, he said, exceeded in number deaths from all forms of tuberculosis The infant-mortality rate had been shown to depend largely on poverty, and there was some evidence that the stillbirth and neonatal death-rates were affected in the same way Thus in Scotland the combined rates were 42 and 35 per 1000, in England and Wales 38 and 26, and in Holland 25 and 21 The stillbirth-rates are influenced by maternal age and parity , thus they were high in first children, though this is partly counteracted by the low infant mortality among first children Burns, in a recent Birmingham report, had shown that for each size of family there was a maternal age which gave each child the best chance of survival In a large proportion of stillbirths the cause, Professor Baird said, is unknown , in another big group difficult labour is responsible, yet there may have been nothing in the maternal condition to indicate the need for cæsarean section In some emergency cases in his experience the child might have been saved if the mother had been admitted during labour Prematurity is an important cause of neonatal deaths, and its prevention offers a difficult problem He believes that notification of prematurity is worth considering , in Chicago (where the infant-death rate is only 31 per 1000) prematurity must be notified within an hour of birth He accepted the definition of a premature infant as one which weighed less than 5½ lb at birth Of 67 neonatal deaths of premature infants in the Aberdeen Hospital in a year, 45 had been from weakness, 20 from infection and 2 from other causes In private patients—that is, among the better-to-do—he had found less prematurity less infection and a lower stillbirth-rate, so that he believed diet to be very important. The incidence of extreme poverty is twice as high in Scotland as in England, and the housing problem 6 times as bad. Experiments on animals at Aberdeen had shown that physical defects such as cleft palate could be produced as regularly as clockwork by faulty diets. In prosperous parts of the country the infantile mortality is low, but the birth-rate is also low and there is a tendency to postpone the birth of the first child. These regions, he thinks, are solving the infant mortality problem at the cost of dying out. The causes of the greater part of our loss of infant life are malnutrition of the mothers, too rapid childbirth, and slum conditions. He advocated better feeding, more rest, and education for the mother, more antenatal beds in hospitals, and better training of doctors, midwives and health visitors. The child should be reared under conditions which allow his maximum development. The low birth-rate he attributes mainly to the financial burden of bearing children.

Prof **Charles McNeil** felt that the first month of life should be the joint concern of the obstetrician and the pædiatrician. The prevention of child death at this age, he said, is partly obstetric, depending on the care received by the mother during pregnancy and labour, and partly pædiatric, depending on the care of the baby. In a series of 5300 viable births, 414 were stillbirths and 236 neonatal deaths (650 deaths in all). The stillbirths were thus the more serious part of the problem and prematurity was a common cause; over half the premature infants died. A new study of prematurity is needed, he considered. In this series, all the infants (68) weighing less than 2½ lb died. He showed slides of the lung and the stomach of a premature infant weighing 2¼ lb. The walls of the alveoli were much thicker and more rigid than those found in the mature child, and the secreting tissue of the stomach was barely differentiated. He advised that in order to save the lives of premature children the pædiatric staff in maternity hospitals should be strengthened. In hospitals the infants must be protected from infection, and it must be borne in mind that the health of the mother cannot be separated from that of the child. A radical study of prematurity by hospital teams should extend into the home during pregnancy and after discharge of mother and child from hospital. A standard of prematurity should include both an upper and a lower weight standard (say 2½ lb, since below that weight 100% of children in his series died).

Sir **Francis Fremantle** considered what could be done on the communal side to abate the stillbirth and neonatal death-rate. Prevention starts in the home and can only end when mother and child return to conditions where they can lead a healthy life. The training of midwives and maternity nurses is going steadily ahead, but the Ministry of Health recognises the difficulty of finding women to undertake this work and of making it attractive enough to keep them. Conditions of service and remuneration must be improved and the education of girls must be such as to attract into it those who are inclined for this work. The work of antenatal clinics and health visitors must be improved and meals and financial help must be provided for necessitous expectant mothers. Housing and institutional accommodation must be extended, and he is confident that there will be a move forward as a result of the war.

Dr **A Doyne Bell** quoted the saying, that the maternal mortality-rate is a yardstick to measure the success of the maternity service. The meeting, however, was not likely, he thought, to regard the baby as a by-product and the neonatal death-rate must be taken as a second yardstick. He quoted from a recent *Lancet* leading article[1] in which the care provided for the baby during the first month of life was shown to be inadequate. This had been prompted by the paper by Dr F J W Miller in the same issue where the inaccuracy of certification was stressed. Prematurity in his view depended only on a time factor, meaning birth before the 40th week, whereas immaturity could be measured by the birth-weight. He referred to the work of J H Ebbs and his colleagues in Toronto, who have compared the results in a series of women on a poor diet with those of women in similar circumstances whose diet was supplemented with milk, eggs, oranges, tomatoes and cheese during the last three or four months of pregnancy. The miscarriage, stillbirth and prematurity rates were found to be much lower in the group with the supplemented diet. The People's League of Health[2] had found that women on supplemented diets were more likely to carry their children to term than controls on a poor ordinary diet, but he thought the numbers investigated had been too small. He agreed with Dr McNeil that the care of premature infants was work for a pædiatrician, and he thought that local authorities should be pressed by the Ministry of Health to provide adequate pædiatric personnel.

Prof **James Young** also discussed the effect of maternal nutrition on the child. It has been known for some years that severe calcium-vitamin D deficiency in the mother was liable to produce rickety children even in the uterus; and Mellanby has shown that puppies delivered by a bitch suffering from vitamin-D deficiency develop rickets after birth even when they are properly fed. It has also been shown in New York that there may be a large amount of subclinical deficiency in children born of ill-nourished mothers. The observations in the People's League of Health report were in his opinion large and well controlled, and the figures had passed the criticism of distinguished statisticians. They were based on the study of 5000 antenatal women in 10 London hospitals. They were divided into 2 equal groups, and 2500 received additional supplements to their diet of calcium, iron, iodine and vitamins A, B, C and D. The remaining women acted as controls. The supplementary diet had reduced the toxæmia rate by about 30% and the prematurity rates by about 17%, and since it was given in the form of tablets it must be regarded as showing the minimal rather than the maximal effect of a good diet. Hargreaves at the British Post-graduate Medical School had studied a large number of booked cases since 1937. The average birth-weights of full-time children has shown a decline since the prewar years from 7·3 to 7·1 lb in primigravidæ and from 7·6 to 7·4 lb in multigravidæ. There had also, however, been a decline in prematurity rates from 19·7 to 14·2 in primigravidæ and 16·7 to 13·6 in multigravidæ.

Professor **Baird**, replying, remarked that a new large-scale experiment had been begun in Toronto. He commented on the appointment of Dr J C Spence as professor of child life at Newcastle, and advocated more appointments of the same kind.—Professor **McNeil** remarked that the chair in question was really a chair of child health. He himself was professor of child life and health, and had spent the afternoon discussing child death. When that was solved, he thought, we could begin on the infinitely larger problem of child life.

BRITISH ORTHOPÆDIC ASSOCIATION

In the course of the annual meeting of the association at Nottingham[3] on Sept 25–26, clinical demonstrations were given at the Harlow Wood Orthopædic and Nottingham General Hospitals.

Mr A N **Birkett** (Nottingham) reviewed the cases of *Fractures and Dislocations of the Cervical Spine* treated by Mr Frederick Crooks and himself at the Nottingham General and Chesterfield Royal Hospitals. During the last 7 years they had seen 59 cases, among 38,000 fractures of all kinds and 626 spinal fractures. Spinous process fractures, they find, can be related to fracture dislocation of the neck or as isolated fractures of the clay shoveller's type, due to direct violence or muscle violence. Falling down stairs was the chief cause in their series and being blown by bomb blast a new one. They believe that if the violence causing the injury was of a kind likely to give rise to fracture dislocation, then the presence of fracture of a spinous process must be taken as evidence that some degree of fracture-dislocation was also present, and the case must be treated with appropriate respect. The clay-shoveller's type of fracture was a separate condition and had not been given enough attention. The fracture-dislocations in the series were mainly at the top or near the bottom of the cervical column. Of those near the top, fracture of the atlas, fracture of the odontoid, and displacement of the atlo-axial joint have received adequate attention in published work, but the effect of the specialised anatomy of the axis or the result of violence upon it have not been sufficiently realised Out of the 52 cases of fracture-dislocation there were 6 at this level not including odontoid fracture and 4 of these were lamina fractures Indeed, lamina fractures are hardly ever seen below the axis He explained the mechanism the large spinous process of the axis is pulled down by the strong muscles of the neck, the anterior part of the body is driven down by the force transmitted through the skull, and the *back* of the axis is broken at the pedicle junction—a new and important observation Chronic arthritis, he finds, may play a part in fractures lower down the neck He showed that deformity of the spine was not inconsistent with a good result and no pain He reduces such fractures by means of a halter with the patient under intravenous anæsthesia —Mr Roland Barnes (Manchester) in the discussion urged the use of skull traction as a routine It does away with the need for anæsthesia which may often precipitate pneumonia in these cases In his cases as soon as the fracture is reduced—and he checks it by X rays every half hour—the weight is reduced to about 4 lb , and indeed only about 1 lb is really needed —Mr K I Nissen found that the Nuffield type of respirator did not exercise enough direct pressure to expel mucus in these cases and he prefers an artificial respirator giving direct chest or abdominal pressure

---

[1] *Lancet*, Sept 5, p 283

[2] *Ibid*, July 4, p 10

[3] See *Lancet*, Oct 17, p 455

Mr Birkett also described *Two Devices for Fracture Treatment* One is used in fracture of both bones of the forearm , treatment is carried out in the vertical plane instead of horizontally as in Bohler's method , and a form of " Chinese puzzle " is applied to two fingers as a source of pull The second device is a method of applying traction to both limbs with the knees flexed at a right angle during the insertion of Smith-Petersen nails in fractures of the neck of the femur This gives perfect control of position and a curved casette fixed to the peroneal support of the table aids lateral radiograph

Mr R G Pulvertaft (Grimsby), in discussing the *Reduction of Epiphyseal Fractures of the Neck of the Humerus*, remarked on the remoulding which occurred in young bones Even in unreduced severe displacements the results a year or two later were almost indistinguishable from normal Open reduction therefore was not necessary In adolescent cases remoulding is not so complete, and he considers that exact reduction is desirable This may be achieved by open operation , he clears the bone ends and impacts them and uses no plates or other internal fixation When once reduced there is no relapse —Mr George Perkins said that whether they were treated or not no disability was seen after such epiphyseal fractures

Mr J P Campbell (Nottingham) reviewed 54 cases of *Fractures at the Junction of the Lower and Middle Thirds of the Tibia and Fibula* with special reference to recent discussions upon delayed union His series indicated that the severity of the violence was an important factor, and he strongly advocates the use of metal shin-guards by motor-cyclists Pin-traction need not materially delay union, but long fixation in plaster does increase the time of disability because of the stiffness which develops in the knee and foot joints Clinical union is often present before radiographical union, and he thinks that movements could therefore often be started earlier —Brigadier Rowley Bristow thought that more efficient protection for motor-cyclists could be provided by guards fixed to the machine

Mr John Grocott (Stoke-on-Trent) discussed *Plastic Surgery in Hand and Foot Injuries* Three advantages of early grafting of gaping wounds, he said, were the avoidance of skin contracture (which could be more disabling than joint stiffness), the relief of pain, and the protection of exposed tendons For free grafts, if the principles of asepsis, hæmostasis and fixation were adhered to, and provided sulphanilamide dusting was used, up to 95% of successes could be expected He has found the razor graft particularly valuable for the covering of tendons which otherwise become adherent and fixed in the open wound In discussing the use of direct flaps and tube pedicle flaps he indicated that by temporarily obstructing the blood-supply, blood flow via the newly attached section can be forced He finds that sensibility in grafted finger-tips gradually returns —Mr Barnes said he had been using a Padgett dermatome for cutting grafts and had found it a great advance He cuts his grafts about 12 μ thick

Mr James Hardman (Sheffield) discussed *Indications for Operative Treatment in Sciatica* with special reference to prolapsed intervertebral discs Other conditions, such as gluteal fibrosis, sacro-iliac disease and disease of the spinal column, have first to be excluded, and conservative orthopædic treatment tried before the patient is submitted to myelography and operation, and close cooperation is needed between the neurosurgeon, neurologist, orthopædist and radiologist The distribution of pain he considers is probably due to compression of muscle afferents, and interference with ordinary sensation is slight in compression of a single root In practice the syndromes of single-root compression are not clear-cut because of the segmental overlap in skin and muscle and the variable relation of the disc protrusion to the midline Of 79 cases of sciatica 26 came to operation, 5 being cauda equina tumours In 20 prolapsed discs were found 7 at the lumbo sacral disc level, all lateral prolapses , and 13 at the disc between the 4th and 5th lumbar, 5 of these being lateral and 8 in the midline When the disc prolapse is central between the 4th and 5th lumbar it is liable to compress the 1st sacral nerve more than the 5th lumbar, and the syndrome will be a mixed one, often bilateral No patient should be operated on without myelography Exact diagnosis is sometimes possible when air is used, and this has the advantage of avoiding the irritating effects of iodised oil If oil is used the amount injected should not exceed 2 c cm He had noticed the loss of normal lordosis in these patients as the result of postural attempts to prevent pain —Colonel Rex Diveley (chief consulting surgeon to the American Army) said that in the United States the orthopædic surgeon often cooperated with the neurosurgeon at the time of the operation by grafting the spine

Mr S A S Malkin (Nottingham), in *Some Observations on Injuries to the Semilunar Cartilages*, reviewed 185 Service patients treated at Harlow Wood Orthopædic Hospital from the beginning of the war until April, 1942 The proportion of external cartilage lesions to those of the internal cartilage were approximately 1 to 3, which is higher than was formerly thought A major cause of disability following the removal of semilunar cartilages is often quadriceps insufficiency In long-standing cases no one particular type of lesion is found , and arthritis in a mild degree has little effect on the length of postoperative treatment Postoperative rehabilitation at a special centre is of the utmost value in ensuring a satisfactory recovery, and operative treatment for lesions of semilunar cartilages is well justified under conditions of segregation in special centres —Group-Captain H O. Clarke remarked that it was not necessary to operate on every case, nor—at the present time—on anybody who can carry on with his job

Mr Frederick Crooks (Nottingham) described three cases of *Spondylolisthesis* which he had operated on by the transabdominal approach He had found it a straightforward operation with no troublesome hæmorrhage, resulting in no shock or abdominal discomfort A portion of the intervertebral disc was removed anteriorly, the contiguous bony surfaces were freshened, a portion of the iliac crest was placed in the gap, and the patient was kept in plaster for four months

Mr Leslie Morris (Leicester) described a condition under the title of "*Athlete's Ankle*" He had seen 5 examples of the condition, which gave rise to swelling of the ankle-joint and tenderness restricted to its anterior aspect The patients were always experts in the particular sport in which they were concerned The type of violence is usually associated with the extreme plantar flexion of the foot, which only the expert in such activities as sprinting or long-distance football kicking can achieve The X-ray appearances were characteristic, there being some new bone formation on the upper surface of the neck of the astragalus and extra bone formation at the posterior edge of the bone The former he thought due to traction and the latter to compression stresses. Hyperextension may result in subperiosteal hæmorrhage with subsequent ossification and spur formation When consulted for the swelling he reassured patients and they continued at their sport after a short period of physical therapy

Reviews of Books

Studies in Hay-Fever and Asthma

DAVID HARLEY, MD Edin, FIC, first assistant in the allergy clinic, inoculation department, St Mary's Hospital, Paddington London William Heinemann Pp 112 10*s* 6*d*

Dr Harley presents some intensive studies on the chemical and immunological nature of the pollen antigen He records experiments showing how the hay-fever idioceptor differs from the anaphylactic and most other antibodies especially in thermolability, precipitation, complement fixation and affinity for cutaneous tissues He also shows that neutralisation of idioceptor by idiotoxin appears to take place only in vivo—that is, by a reaction involving tissue cells Dr Harley considers that the factor determining whether a person develops allergic symptoms or not is a hereditary one, and connected with the inability of the blood to digest some constituents of the pollen grain He describes the methods of desensitisation employed at the hay-fever clinic at St Mary's Hospital only Timothy grass pollen is used there for testing and desensitisation, though observers in other clinics in Great Britain and abroad do not agree that all hay-fever sufferers react to Timothy grass pollen, or that all sufferers respond to desensitisation with that extract alone, No mention is made of other complicating sensitisations such as feathers, dust, orris root and animal hairs in seasonal hay-fever cases Dr Harley produces conclusive evidence that skin sensitivity is reduced and can even be abolished entirely if suitable doses of grass pollen are given The book is a close technical study of hay-fever, valuable for the expert

War Injuries of the Chest

Editors H MORRISTON DAVIES, M Chir Camb, FRCS, ROBERT COOPE, MD Lpool, FRCP. Edinburgh. E and S Livingstone Pp 131 6*s*

THIS handbook is the outcome of the experience and views of an EMS chest surgical unit whose staff have combined smoothly and easily to produce something full of information and practical advice Arranged on conventional lines, it starts with anatomy, physiology and pathology, and passes to clinical considerations and thence to the actual treatment of injuries, ends with after-care and a good chapter on anæsthesia

The diagrams in the first chapter are helpful and instructive but their promise is not upheld in later pages The effects of atelectasis of different lobes are particularly well illustrated in a series of line drawings Readers are reminded that shock, multiple wounds and hæmorrhage may cause a chest condition to be overlooked In the early stages of treatment the value of high concentration oxygen inhalation and plasma- or blood-transfusion is emphasised If the need for transfusion is urgent rapid administration by more than one vein is advisable Reasons for evacuating a sterile hæmothorax and the behaviour of blood in the pleural cavity are discussed, though some of the points made are controversial Instructions for the care of abdomino-thoracic wounds are clear, many tragedies could be avoided if surgeons remembered that, owing to the height to which the diaphragm rises in the chest, abdominal viscera may be damaged as well as chest contents Early closure of all open or sucking wounds of the chest is rightly held to be of paramount importance, and the danger of increased intrapleural pressure from fluid or air or both should be borne in mind When discussing the treatment of penetrating wounds the indications for early operation and the procedure for delayed handling of retained foreign bodies are detailed, but there is not enough mention of "through and through" injuries caused by bullet wounds The chapter on anæsthesia is able Attention is drawn to the danger, not always fully recognised, of nitrous oxide, particularly if a CO_2 absorber is used, in spite of a good colour, due largely to absorption of CO_2 from the circuit, the patient with a chest injury may be close to the borderline of anoxia, and this may show itself suddenly and disastrously With the increased experience that warfare brings some of the views expressed in this book may have to be modified, but as it stands it is a sound expression of thoracic practice at the present time

Blood Disorders in Children

I NEWTON KUGELMASS, MD, PhD, ScDspec, attending pediatrician, Downtown Hospital and Pan American Clinics London Humphrey Milford, Oxford University Press Pp 897 60*s*

INFORMATION about the blood disorders of children is scanty A book dealing with them ought to be clear and it should not be necessary to include material to be found in regular hæmatological textbooks Dr Kugelmass's desire for completeness traps him into a welter of detail For instance, chlorosis, ulcerative colitis, hæmorrhoids, schistosomiasis, amyloidosis, *Diphyllobothrium latum* infection, trypanosomiasis, Addison's disease, Simmonds's disease, favism, pernicious anæmia, and gastrectomy are given as causes of anæmia in a book purporting to deal only with children's diseases, 62 causes of symptomatic polycythæmia are given, 87 of neutrophilia, 48 of leucopenia, including mustard gas and pernicious anæmia, 67 of eosinophilia, and 37 of granulocytopenia, among which he cites polonium intoxication Yet he fails to give helpful detail thus the diet in cœliac disease is dismissed as "largely of protein and monosaccharides", but a "deleading" diet is given fully The same criticism applies to the section on treatment, for example, treatment of congenital hæmolytic icterus is listed as "Prevent exhaustion Eliminate infections X-ray therapy Splenic ligation Splenectomy"—the most important coming last The illustrations are unworthy of a 1941 textbook and large drawings of how to give rectal feeds, intravenous injection into an arm vein, and other ordinary procedures are out of place There are a few useful sections, but only a persistent reader would have the patience to discover them

Your Mind can Heal You

FREDERICK W BAILES London George Allen and Unwin Pp 242 7*s* 6*d*

THIS is much the sort of book that its title suggests "A little capsule sitting atop each kidney busily manufactures adrenalin which keeps the heart beating These adrenal glands are no larger than one's finger nail" is a specimen of the author's physiology and anatomy, references to the Master Chemist of the Universe, Universal Subjective Mind, the Great Triangle, God's Perfect Idea, give the temper of his psychology His teaching is like what the reviewer supposes that of Christian Science to be, but perhaps there are doctrinal differences

Diseases of Metabolism

Editor GARFIELD G DUNCAN, professor of medicine, *Jefferson Medical College, Philadelphia* London W B Saunders Pp 985 60*s*

Professor Duncan's aims have been "to provide a practical basis for the understanding, diagnosis and treatment of the various metabolic disorders" Fifteen experts, some of them with international reputations, have contributed articles or parts of articles and there is a short foreword by the late Sir Frederick Banting The text covers basal metabolism, the metabolism of carbohydrates, proteins, lipids and minerals, water balance in health and disease, blood diseases in so far as they are diseases of metabolism, the various vitamins and avitaminoses, undernutrition and obesity, and such metabolic disorders as gout and diabetes, the endocrine disturbances have not been included except in so far as they influence metabolic disease The book is good but uneven, some of the pictures are useful and instructive, but there are too many photographs of vitamin crystals and the coloured print of a pancreatic gland containing an enlarged lymph-node and a small islet tumour might well have been omitted The difficult editing has been well done, a little overlapping was almost inevitable Most parts of the book are quite up to date, but the paragraph on refractory rickets is disappointing and there are a few minor passages—notably those dealing with alimentary and essential pentosuria and with the unavailable carbohydrates of the diet—which seem to have been taken from older textbooks The references on the whole are adequate, American publications predominating The book can be recommended to advanced students, lecturers and all interested in the progress of scientific medicine

THE LANCET

LONDON, SATURDAY, OCTOBER 31, 1942

JAUNDICE AFTER YELLOW FEVER INOCULATION

THE Secretary of State for War told the House last week that all the British troops proceeding to endemic areas have been vaccinated against yellow fever since before the war During the war three cases of the disease have been diagnosed in British troops but the vaccine itself has produced no cases of jaundice or other ill effects This question was no doubt raised because of the recent cases of jaundice following yellow fever vaccination in United States soldiers, of which a full official account was published a few weeks ago [1]

Occasional instances of jaundice have been recorded after the inoculation of vaccines and sera in the past but little significance was attached to them until 1938, when MACNALTY [2] and PROPERT [3] observed a number of cases of jaundice with a considerable death-rate in children inoculated with a batch of convalescent measles serum This batch was a pool of the sera of many donors from different parts of the country, none of whom gave any history of jaundice At about the same time jaundice after the inoculation of yellow fever vaccine was reported by FINDLAY and MACCALLUM [4] in England It was shown that this was not the result of the action of the yellow fever virus, and it was suggested that it might be caused by an infectious agent present in the human serum used for suspending the virus, and that this agent was carried in the tissue cultures used for growing the virus [5] A similar occurrence was recorded in Brazil by SOPER and SMITH [6] In England a fresh start was made in November, 1937, with a strain of yellow fever vaccine virus from the laboratories of the International Health Division of the Rockefeller Foundation in New York and the human serum used was heated to 56–60°C for at least 30 minutes before inoculation No cases of jaundice have been attributed to the vaccine in many thousands of inoculations since that time FOX and others [7] have recently reported a similar occurrence in 1939–41 in Brazil Among approximately 107,000 people who were inoculated with the incriminated batches of vaccine in 1940–41 there were 1072 cases of icterus Several batches of vaccine were incriminated with varying percentages of icterus in the groups inoculated with them but the most interesting fact was that the incidence of jaundice covered a wide range of 0–19% in different groups in different areas inoculated with the same lot of vaccine This suggested the probability of some causative factor in addition to the inoculation Another interesting finding was the preponderance of cases among adults The latest addition to this extraordinary series of events is the report [8] of 28,585 cases of jaundice among USA army personnel inoculated with yellow fever vaccine between Jan 1 and July 4, 1942 The evidence points to the same sequence of events and clinical findings as in the previous instances The incubation period ranges from 6 weeks to as long as 6 months, with the majority of cases 10–15 weeks after inoculation The cases greatly resemble those seen in infective hepatitis or catarrhal jaundice, though the incubation period in the latter disease is generally accepted as about 20–35 days One point of note is the presence of urticaria in about 20% of cases, a condition hardly ever seen in ordinary infective hepatitis, that disease, too, is usually a disease of children and adolescents, who seemed more or less immune to the post-vaccination condition in Brazil One of the most notable differences has been the absence of contact cases in places where there were cases of jaundice in the midst of many times their number of unvaccinated or non-icteric postinoculation men The cases which followed the use of measles convalescent serum fit into the same picture as the postvaccination cases except for the two possible contact cases and the much greater severity of the disease But here again the severity has varied widely in the different postvaccination incidents, and if the serum is to be incriminated one must realise that the measles children received several hundred times the dose given in yellow fever vaccine

The last two "outbreaks" tend to confirm the earlier view that the normal human serum used in production was responsible, and in Brazil, where fertile eggs are sufficiently plentiful to make it possible, the serum has been dispensed with and no cases have occurred in 164,000 people vaccinated with the new vaccine The vaccine produced in New York has also been modified, presumably along the same lines All the evidence clearly indicates that the lesion is not the work of the yellow fever virus Pathological material has not revealed any new specific lesion, the main feature being various degrees of subacute and acute necrosis beginning in the central zone of the liver lobule The condition has not yet been reproduced in animals

MASKED HYPERTHYROIDISM

FRANK hyperthyroidism is easy to diagnose, but it was realised as early as 1883 that cases do not always conform to type In that year MARIE pointed out that cases of Graves's disease did not necessarily have goitre or exophthalmos, and CHARCOT, a little later, described formes frustes in which struma, exophthalmos and even tachycardia were lacking These cases of atypical hyperthyroidism have periodically attracted attention, and cardiologists have for some time emphasised the importance of considering occult hyperthyroidism as a cause of cardiac failure with auricular fibrillation It is not only as a circulatory disorder that hyperthyroidism may be disguised, for cases presenting as gastro-intestinal disease have been described, while SHORR,[1] and MCEACHERN and ROSS,[2] have recently drawn attention to a group suggesting myasthenia gravis or progressive muscular atrophy Many cases of masked hyperthyroidism continue to pass unrecognised, and BREIDENBACH and APPELBAUM [3] of New York report 12 further examples

[1] Personel communication to Breidenbach and Appelbaum

[2] McEachern, D and Ross, W D *Brain*, 1942, 65, 181

[3] Breidenbach, L, and Appelbaum, E *Ann Surg* 1942, 115, 154

Most of their patients were women past middle age, and initially were misdiagnosed, the diagnoses varying between heart disease, a gastro-intestinal disturbance, diabetes mellitus, hypertension and tuberculosis, the commonest being some circulatory disorder. In all their cases exophthalmos and enlargement of the thyroid were absent or exceedingly slight, and the patients showed neither tremor nor sweating. Nervousness was uncommon. On the other hand, all their cases had lost weight and all complained of muscular weakness, so that even a diagnosis of malignancy was entertained. This important symptom of asthenia and fatiguability is outstanding in the rare group of cases of thyrotoxic myopathy described by McEACHERN and ROSS. In one of these the myogram showed a typical myasthenic response which became temporarily normal after injection of prostigmine and permanently so after thyroidectomy. This asthenia is also a cardinal symptom in the picture of myasthenia gravis and dermatomyositis, and these apparently diverse diseases have other similarities. They all show in the lymphocytic infiltration of muscles an identical histological picture, and, biochemically, an increased creatinuria, which only in cases of thyrotoxicosis and thyrotoxic myopathy can be controlled by thyroidectomy. The significance of this observation is not clear.

The picture of Graves's disease is a composite one with three main groups of symptoms—those associated with the nervous disorder, the group of eye changes, and the group related to hypermetabolism. Each group may occur independently of the others. The nervous disorder is often indistinguishable from an anxiety state unassociated with increased metabolism. Exophthalmos is often seen in a benign form, sometimes accompanying essential hypertension, though as EDEN and TROTTER[4] have lately recalled, lid-retraction is almost pathognomonic of Graves's disease. It is only the signs and symptoms of hypermetabolism that are diagnostic of hyperthyroidism and that thyroidectomy can be certain to relieve.

The cases of masked hyperthyroidism show muscular weakness with hypermetabolism, usually presenting as a form of cardiac failure. The reason for this deleterious effect of hyperthyroidism on the heart remains obscure. It is either some toxic action on the heart direct, or more probably the result of enforced overwork on an already damaged myocardium. It is therefore more often met with in the elderly. Hyperthyroidism plus infection seems particularly overwhelming to the heart muscle. Is this group of cases, where evidence of hyperthyroidism is partly lacking, more exactly described as hypermetabolism?[2] HINTON and his associates,[5] in examining the rôle of iodine in thyroid disease, assume that hypermetabolism may not only occur apart from Graves's disease but is often confused with it. Difficulties in investigation are partly due to the lack of any simple means of measuring the function of the thyroid other than by the indirect method of measuring the metabolic rate. If hypermetabolism is distinct from hyperthyroidism, the inferences drawn from this procedure are obviously fallacious. Since the thyroid is largely concerned with iodine metabolism, investigation of that function might throw direct light on thyroid disease, and it is largely the technical difficulties of blood iodine estimation that have prevented more work on these lines. HINTON and his colleagues have done a large number of blood-iodine estimations and in the great majority of their cases of recent exophthalmic goitre high values were encountered. Unfortunately they have done no measurements on cases of masked hyperthyroidism. They consider that high values in cases of non-thyroid disease always indicate undue exposure to iodine. Possibly if estimations were limited to the organic iodine fraction of the blood, a *fraction presumably representing the thyroid hormone,* results might be more accurate and the confusion that exists between hypermetabolism and hyperthyroidism would be dissipated. Till then the occurrence of masked hyperthyroidism must be borne in mind, more particularly because as a rule surgery can effect a cure.

INDUSTRIAL HEALTH IN 1941

SIR WILFRID GARRETT is still convinced that if maximum production is to be obtained the general requirements of the Factories Act must be observed. In his report[1] he assumes that accident prevention, proper ventilation and heating, and reasonable hours of work are essential to the war effort, although he has to spend a good deal of time in convincing other Government departments that this is so. His own department is giving much thought to the immediate well-being of the workers and personal relations in the larger factories. By the end of the year under review, with the help of advisers expert in domestic science, catering and nutrition, canteens had been provided in 6592 places subject to inspection by the Factory Department. These advisers spent their time visiting canteens and giving detailed advice on equipment, staffing, menu-planning and the nutritional problems of big-scale cookery. The department itself was kept busy at first with getting the canteens built and equipped, but now there is time to see that the meals are of the right quality and that the best use is made of the raw materials. Dr J C BRIDGE, senior medical inspector, ascribes the maintenance of the workers' health in large part to the canteens, although he is not quite happy about the vitality of workers in the heavy industries. No statistical evidence has been produced in favour of the wholesale distribution of synthetic vitamins, and Dr BRIDGE thinks the money spent on these would be better employed in cheapening canteen meals. In general, women have not suffered from the new factory jobs they have undertaken, but he is against employing women who have had children on work that requires much strain on the abdominal muscles. He has been struck by the way women unused to industrial life fit into a team which includes men, and how readily the men lend them a helping hand. The temporary increase in the hours of work of young persons has had no harmful results as far as direct evidence is available. Much good has come of the Rest Break Houses Scheme which provides tired workers with a holiday in the country at low cost. The scheme is not intended for convalescence after illness but for preventing a tired worker from becoming ill. Dr BRIDGE would like this organisation to be better known and adopted more widely. A similar scheme for civil defence workers, sponsored with great devotion by the war organisation of the Joint Red Cross, is commended on a later page by Lord HORDER to medical officers of health

[1] Annual Report of the Chief Inspector of [illegible] 1941 Cmd 6397, HMSO, 6d

Turning to specific industrial diseases we note that only 59 cases of lead poisoning were reported, the lowest figure since notification became obligatory There were more cases of aniline poisoning or so-called anilism, many of them among TNT workers In addition there were 41 cases (12 males, 29 females) of toxic jaundice caused by TNT, and of these 12 (3 males, 9 females) were fatal The high proportion of women may not be due as much to susceptibility as to the greater number exposed to risk of poisoning One woman died from liver damage set up by exposure to the dust or fume of chlorinated naphthalene wax There were 22 cases of anthrax with 3 deaths, against 37 and 5 in the previous year, a reduction probably due to the restricted import of infected material The only case of industrial phosphorus poisoning since 1919 was reported during the year Gassing accidents were 200 more with 10 more deaths than in 1940, the increase being greatest in CO poisoning Blast furnaces, the common source of such poisoning, were less guilty than usual but there were 56 more cases with 9 deaths from coke braziers, exhaust gases and similar risks SIR ERNEST GRAHAM-LITTLE has called the attention of the Commons to a rise in the number of cases of industrial dermatitis (as shown by a system of voluntary notification) from 2000 in 1938 to 5000 in 1940, the increase is not surprising in view of the numbers employed and the greater use of irritating material DR BRIDGE maintains that few workers should suffer were proper care taken of the skin He thinks that effective and supervised washing will prove to be the essential factor in prevention

TUBERCULOSIS IN EIRE

A LONG STANDING tradition has it that the Irish are particularly susceptible to tuberculosis, and the tradition is supported by two facts The first is that the tuberculosis death-rate in Eire is relatively high—123 4 per 100,000 in 1939 compared with 69 5 for England and Wales The second is that in Irish communities living abroad the death-rate from tuberculosis has been found to be significantly higher than in the rest of the population, this observation has been inadequately investigated Before accepting so vague and unanalysable an element as racial susceptibility, other points of comparison must be fully determined, such as social conditions and the frequency of primary infection in childhood and adolescence In the presentation of the American figures,[1] the possibility that economic differences were responsible was not eliminated BRADBURY's[2] figures for Tyneside are impressive, and environmental factors there were taken seriously into account, but the question of primary infection was not investigated

Turning then to the high tuberculosis mortality in Eire, the problem reveals itself as bristling with complexities To compare fairly, for instance, the death-rates in Eire and England, it is essential to know whether standards of living, of housing, medical habits of the people (readiness of the patient to consult), incidence of infection, and development of the medical and especially of the tuberculosis services are comparable in the two countries In a recent analysis, DILLON[3] has dealt with some of these factors The mortality figures show a high prevalence, and especially a well-marked slowing down in the rate of decline, as opposed to the acceleration of the decline which took place in other countries up to the outbreak of war Thus for a total of 19 other countries the mean decline of the death rate was 3 2% per year during the decade 1927–37, compared with 2 0% in the preceding 15 years In Eire the decline has, on the contrary, been strikingly less—1 5% each year in 1927–37 against 2 1% for the earlier period The result is that the tuberculosis death-rate in Eire was in 1937 higher than in all but one of the 19 other countries whose figures are available DILLON stresses two main points anti-tuberculosis services and economic conditions He finds that the decline has been very definite in those countries whose anti-tuberculosis services were extensively reorganised in the postwar years In Northern Ireland, where such reorganisation took place, the death-rate fell from 141 in 1927 to 97 7 in 1937 while in Eire it fell from the same high level (145) only to 123 4 But in Eire DILLON says, "the reorganisation has been deplorably insufficient, and modern diagnosis and treatment are available to a minority only " He describes at length the paucity of the services available in Eire for the tuberculous patient, and makes suggestions for their improvement His description of the existing services is amply confirmed by other contributors to the symposium in which his study appears The factor of economic conditions also looms large in the analysis of figures given During the period 1927–37 primary foodstuffs became dearer in Southern than in Northern Ireland There was also a considerable difference in the purchasing power of the unemployed families, the allowances to both insured and out-of-benefit workers in Northern Ireland were on a much higher scale than in the South In fact the relative excess of mortality in Eire appears to have been mainly experienced by the unemployed section of the population, since the mortality among insured males is less than half that of the general male population between the ages of 16 and 25 Economic distress, overcrowding, badly organised health services for those who are completely dependent on them, are sufficient in themselves to account for a high mortality-rate in tuberculosis

The incidence of tuberculous infection has been studied in small tuberculin surveys carried out in Dublin[4] and in a rural district [5] They seem to indicate, as do the figures of the Prophit Tuberculosis Survey in England,[6] that the incidence of infection in Irish children and adolescents is relatively low This results probably in a relatively high rate of primary infection among young adults and a high mortality The prevalence of tuberculous disease in Eire is difficult to determine, since notification there is compulsory only for cases with positive sputum The full extent of the problem has then yet to be assessed, but on the strength of the figures available there is clearly scope in Eire for a vigorous anti-tuberculosis campaign in case-finding, economic provision, and extension and development of the tuberculosis services While Eire has at her disposal a whole armament of effective measures still to be used in the anti-tuberculosis campaign, speculation about the hereditary factor must remain in the background

Annotations

SKIN PIGMENTATION AND RADIOSENSITIVITY

FAIR skin is known to react to sunlight more readily than dark, and this is true of both the early inflammatory response of sunburn and the later and graver, though rare, sequel of cancer There has, however, been no obvious reason to suspect that a lack of pigment would influence the cutaneous reactions to X or γ rays Harvey[1] of Edinburgh, however, in an informative review of the effects of irradiation on the skin, says that "Swarthy individuals appear not to be highly radiosensitive, just as they are not highly tar or paraffin sensitive" This suggestion is worthy of further inquiry, for if confirmed it will be of fundamental importance in radiotherapy Writers on experimental cancer do not seem to give a clear answer to the question whether neoplasia can be more readily induced by chemical carcinogens in albino than in coloured mice, and radiologists differ on the relative sensitivities of fair and dark patients to the more immediate reaction to X or γ rays Two circumstances might lead to an erroneous belief that the fair are more susceptible than the dark to carcinogenic agents First, tar workers become sensitised to the action of sunlight, sometimes to an advanced degree This increased sensitivity would probably be most pronounced in the fair, and it might be misinterpreted as due to the tar alone and not, as it possibly is, to the greater dose of ultraviolet radiations which the unpigmented skin has to accept Secondly, when we consider cancer, experiments leave little doubt that one factor may be added to another to increase the likelihood of ensuing neoplasia The carcinogenic effects of sunlight may be added to those of tar in causing cancer of the skin, in which event the fair would show a higher incidence of neoplasia than the dark Such an increased incidence would be most pronounced and perhaps confined to the parts exposed to sunlight, and it would be wrong to attribute the result to an exaggerated susceptibility of the fair to the carcinogenic action of tar The problem, however, is not to be solved by argument without accurate data

HOSPITAL REPORTS

IN England, hospital reports are mainly the prerogative of the London hospitals Some of us vexed our minds in the days of peace, and will do so again when those days return, over the raison d'etre of such publications, and the form they should take They may be divided into two broad categories those which contain original articles, and those which collect together the papers published elsewhere by members of the hospital staff Of the former type *Guy's Hospital Reports*, which started in the early years of the nineteenth century, are perhaps the best known example, though St Thomas's and St Bartholomew's publish similar types of reports The London and the Middlesex Hospitals issue collections of published papers, actual reprints being bound loosely within covers The *Brompton Hospital Reports* are intermediate in format and character, consisting mainly of papers already published, reset in the form of a book, but occasionally including papers which have not previously appeared, along with brief tabular summaries of aspects of the work of the hospital Sir Robert Hutchison[2] has drawn attention to the mass of medical journals which before the war were threatening to make life unbearable for the conscientious doctor, and it may be asked whether hospital reports justify their place in this gargantuan collection For the dissemination of knowledge it seems better to publish material in a journal which has a large circulation Moreover if the editors of reports have to spend much time in persuading their colleagues to write papers, and if these when written are mere pot boilers, then practice is falling short of principle Collections of papers which have appeared elsewhere, though they have not this weakness, may trouble the librarian, because he never knows whether to index them as a separate volume or as separate papers, but they do let the world know what work has been done in the hospital

Reports might serve a useful purpose in two forms either as statistical tables based on all the cases passing through the hospital during the year, and giving details of diagnosis, prognosis and results of treatment, like the old *St Thomas's Hospital Reports*, or as a series of papers based on cases which have been in the hospital—dealing, for example, with the prognosis of ulcerative colitis, or the comparative results of different forms of treatment of thyrotoxicosis, or the incidence of malnutrition in patients suffering from pneumonia These papers would be written largely by registrars or junior members of the staff, with the cooperation of the senior members, and would provide information not otherwise available They would also stimulate careful case recording and filing, and encourage junior members of the staff to carry out adequate investigation There have in the past been periods of lustre in this or that medical school when the genius loci has transcended its walls and become an inspiration to the whole of medical thought Records of such periods have a proper place in the archives of medicine

CAUSES OF BLINDNESS

IN 1935 there were 75,810 people on the Register of Blind Persons in England, Wales and Scotland, 70% of this number being over the age of 50 and 80% being unemployable This figure does not represent the whole of the blind population, for registration of the blind is not compulsory and is only undertaken when the sufferer seeks help, whether as a blind pension, increased public assistance, technical training, free travelling facilities, or wireless licence The standard of blindness chosen is that they shall be "too blind to perform work for which eyesight is essential," and in practice this is equivalent to a vision of less than 3/60 in each eye, or if the visual fields are constricted of not more than 6/60 in each eye A regional clinic for the certification of blind persons in Glasgow and south west Scotland was established in August, 1929, and a detailed review of the information collected has now been presented by Marshall and Seller[1] Before the establishment of this clinic, admission to the Register of Blind Persons was allowed on the evidence of a certificate from a registered medical practitioner, who had not necessarily any specialist ophthalmic knowledge The information gained from this register was too inaccurate to be of any use, and it was to put an end to this unsatisfactory state of affairs that the clinic was started The examiners, four ophthalmic surgeons, work in pairs Two sessions are held each week, at each of which about 12 cases are seen All data collected at these sessions are recorded and tabulated according to the Hollerith system In all, 3219 blind people were examined, and all relevant details recorded In assessing the importance of different causes it was found that a different result was obtained if the second eye was taken as the cause of blindness than if the first was chosen The results published are on the basis of the second eye, and thus if one eye is blind from myopia and the second eye is blinded by injury that person's blindness is classified under injury They found that 16 8% of all blindness was due to cataract and that this was the most important single cause This is unexpected, for if that is the only trouble it is eminently suitable for operation and restoration of useful vision The report goes on to say that of the 540 cases of cataract examined there was a prospect of restoration of useful vision in 306 cases (56 7%) Of the remaining 234 cases, 133 had received treatment which had failed to restore vision, while in a further 96 the treatment was incomplete It is remarkable that 306 people should have allowed themselves to become so blind as to seek for help from the state without, apparently, seeking expert medical advice One is also left wondering why treatment failed to restore vision in 133 cases If the cataract was removed and a retinal lesion prevented useful vision then the cataract was not the cause of blindness Perhaps these 133 cases represented operative failures, with perhaps a few in which congenital cataract had resulted in amblyopia A close second is myopia, with 526 cases (16 3%) The actual cause of blindness in this condition varies with the age of the patient—retinal detachment in the young, choroido retinal degeneration in the middle aged, and cataract in the elderly The sexes were equally represented, and there was not the preponderance of injury among the myopes that one might have expected, nor was myopia more common in one occupation than in another The majority of myopes attending the clinic had more than 10 D of myopia Venereal diseases took third place as a cause of blindness, accounting for 13 9% of the whole Of this number, 99 (3 0%) were due to ophthalmia neonatorum, and 348 cases (10 8%) to syphilis The Kahn reaction was carried out on at least two-thirds of the patients attending the clinic, and where positive was confirmed by the Wassermann Among the blind in this analysis 562 patients, or 17 4%, were syphilitic This is the incidence of syphilis in the blind population and not the number of cases blinded by syphilis The actual eye defects were chiefly interstitial keratitis in the young and optic atrophy in the old The incidence of ophthalmia neonatorum and congenital syphilis have fallen in Glasgow of late years in a remarkable fashion, the former from 5 45 per 1000 births in 1921 to 1 40 per 1000 in 1936, and the latter from 11 84 per 1000 in 1922 to 1 62 per 1000 in 1937 The remaining causes were chronic septicæmia—chiefly iridocyclitis—10 7%, glaucoma 8 7%, congenital anomalies 7 45%, and injuries 6 4% A fairer picture of the disability produced by the different causes of blindness is attained by estimating the "patient years" of blindness Cataract thus falls from 17% to 5% of the total and ophthalmia neonatorum rises from 3% to 10% Unlike in most continental countries, blind pensions are given here whether, in the opinion of the examiners, the blindness is curable or not The compilers of this report thought that this was one factor which accounted for the large number of people who, although advised that treatment might remove them from the blind category, did not in fact avail themselves of this advice

BLOOD-SUPPLY OF NERVES

It has often been assumed that the normal activity of the peripheral nerves is independent of their blood-supply, but the work of Lewis and his school has established close relationship between ischæmia and nerve function From the review by W E Adams[1] of the widely scattered and little known writings on this branch of anatomy it emerges that in every nerve there is an extensive intraneural plexus whose meshes extend into the endoneurium in relationship with the nerve-fibres A distinct macroscopic longitudinal arterial pathway is formed by primary anastomoses between the ascending and descending rami of successive nutrient arteries Such a blood-supply is fundamentally regional and follows a common pattern throughout the mammals The vessels have a well-developed muscular tunica media, from which it may be inferred that they are themselves subject to nervous control But as yet we know little concerning this, though sympathectomies have been widely practised on the empirical assumption that vasoconstriction is thereby inhibited Experimental devascularisation of nerves dates back to 1878, when Mayer found that the treated nerve lost its excitability in 15–30 minutes, and Okada claimed in 1905 that degeneration of the sciatic nerve can be produced by ligating the inferior gluteal artery It appears however that ischæmia need not be complete in order to produce significant effects on the transmission of the nerve impulse Such effects comprise widespread disturbances of sensibility and of motor activity The larger, rapidly conducting, fibres seem to be first affected, and the ischæmic paralysis is completed by the involvement of the slow-conducting fibres These considerations have an important bearing on such clinical conditions as the peripheral neuritis of arteriosclerosis, diabetes mellitus, and the rarer examples of periarteritis nodosa and amyloid disease which involve the nerves, also the circulatory disorders resulting from long exposure of the extremities to severe cold

ELECTROCARDIOGRAM IN TRAUMA OF THE HEART

Contusion of the chest may temporarily or permanently derange the heart, even though the clinical signs and symptoms of cardiac involvement are slight In the recognition of such complications the electrocardiogram is often helpful, but Barber[1] points out that the record should be obtained as soon as possible after the accident if temporary effects are to be studied The electrocardiographic changes seen consist principally of alterations in the T wave, a "coronary thrombosis" type of curve various grades of heart-block and certain arrhythmias Beck[2] noted prominent T waves as well as the typical changes of coronary thrombosis, findings which he also obtained in dogs after contusion of the myocardium Transient changes in the shape of the T wave have also been recorded by Kissane[3] and Warburg[4] and the latter has reported auricular fibrillation In dogs Kissane has produced varying grades of auriculoventricular heart-block, and Coffen[5] has reported its occurrence in man Anderson,[6] in reporting a case, describes inversion of the T wave and RT deviation, changes which had not altogether disappeared a year after the accident although the patient had made a complete clinical recovery In their experiments on blast Zuckerman and his co-workers[7] found only transitory changes in the electrocardiograms of rabbits which recovered, these consisting of alternation of the QRS complex, though in one animal the P–R interval was prolonged Among 33 patients admitted to hospital on account of a severe blow over the front of the chest or some crushing injury of the thorax, in all of whom examination was completed within 48 hours of the accident, Barber[1] found one case of partial heart-block, one with sinus bradycardia, one with slurring of the R waves, one with increased amplitude of the T wave, and 4 with inversion or flattening of the T wave These changes in trauma of the heart are presumably due to one or more of four mechanisms The contused area of myocardium, with or without hæmorrhage, will either affect conductivity in the myocardium in the same way as an infarct does, or will directly interfere with conductivity in the bundle of His If the damage involves the pericardium changes in the latter part of the ventricular complex will ensue The other possibility is that suggested by Schlomka[8]—that the trauma may cause

sufficient spasm of the coronary arteries to produce an infarct of the myocardium The practical implications are clear Every patient with a severe injury involving the thorax should have an electrocardiogram recorded as early as possible and certainly within 48 hours of the accident Even though the correlation between clinical and electrocardiographic evidence of cardiac damage in these cases is not very close, most cases with definite cardiac damage will show some electrocardiographic changes, and since the clinical signs of such damage are often masked by the more direct effects of the accident, evidence which permits of direct diagnosis of involvement of the heart will prove invaluable Any patient in whom such evidence is obtained should be treated, so far as the heart is concerned, on the same lines as a patient with coronary thrombosis In this way the mortality from rupture of the heart, which is liable to occur about a fortnight after the accident, will be reduced, and the risk of a cardiac aneurysm developing will be considerably diminished

MECHANISM OF CONVULSIVE THERAPY

THE last twenty years have brought a succession of physiotherapeutic methods for the treatment of mental disorders—insulin therapy by Meduna, cardiazol treatment by Sakel, electric shock therapy by Cerletti and Bini, and prefrontal leucotomy by Moniz There has not yet been time for any final assessment of their relative efficacy, but it seems that insulin is to be preferred for the treatment of recent cases of schizophrenia, convulsive therapy and particularly electric shock for the endogenous affective psychoses, and prefrontal leucotomy for obsessional and anxiety states and possibly for long-standing chronic schizophrenia All these methods rest on a more or less empirical basis and little is known about how they effect improvement, nor have they yet thrown much light on the nature of the pathological processes underlying the various psychotic syndromes Two papers have recently appeared bearing on this last problem Heilbrunn and Weil[1] found histological evidence of multiple small hæmorrhages within the brain and spinal cord and their meninges in rabbits subjected to electrical shock, and they raise the question whether similar damage occurs in man during electric convulsive therapy In discussing their paper Neymann rightly points out that the currents employed by Heilbrunn and Weil are proportionally much more intense than those used in the treatment of human beings, and that whereas more than half the animals showed subsequent paralysis of the hindlegs no case of serious paralysis in man has yet been recorded It is therefore doubtful whether the findings in these experiments have any bearing on the mode of action of electric shock therapy Levy, Serota and Grinker[2] investigated the electroencephalograms of 23 patients treated by convulsive therapy "Abnormalities" suggestive of disturbed cerebral function were found in 50% of the post-convulsive records, and in addition changes in intellectual function were found in 45% Both the electroencephalographic and the intellectual disturbances were only transitory, and disappeared sooner or later in all cases Furthermore, clinical improvement and recovery showed no direct correlation with these observed alterations in cerebral function It is not possible with our present knowledge to draw any definite conclusions from these findings, the electrophysiologists are extremely cautious in their interpretations of the abnormalities recorded by the electroencephalogram Recent work, as yet unpublished, shows that the occurrence of slow diffuse waves in any record is to a large extent a correlate of age, being extremely frequent in childhood and becoming increasingly rare with advancing age Two other factors of importance in determining the frequency of abnormal findings are CO_2 tension and the blood sugar, though many other factors play a minor part Convulsive therapy may act by temporarily damaging part of the cerebral cortex, or by disorganising its functions, so removing cortical inhibition Indirect support is given to this view by the beneficial effects resulting from section of the prefrontal tract by Moniz's operation, but it must as yet be regarded as purely hypothetical

INFANTILE CIRRHOSIS OF THE LIVER

CIRRHOSIS of the liver is rare in European infants but prevalent among Indians of all social grades in overcrowded and damp districts The familial incidence, A E Sundareson[1] suggests, may indicate the passage of a cirrhotogenic factor from the mother to the fœtus He has demonstrated experimentally that liver poisons such as carbon tetrachloride can diffuse through the placenta in the rat and produce changes in the liver of the fœtus without affecting the permeability of the placenta itself It is notable, however, that breast fed infants are unlikely to develop cirrhosis, which suggests that the condition is postgenital Krishna Rao[2] quotes the case of twins, one breast fed and one fed on cow's milk, the bottle-fed child developed cirrhosis and the other did not Rao describes the clinical and pathological findings in the condition and suggests two ætiological factors devitalisation of the liver by a gastro intestinal upset due to cow's milk, and a secondary *Bacillus coli* infection He claims to have grown *B coli* from the livers of 4 cases in which autopsies were done ½–10 hours after death In 20 cases of sudden death from other causes he was unable to demonstrate the bacillus in the liver Bacterial invasion of tissues after death is likely to be rapid in India, and these findings in so few cases must be regarded cautiously, although the associated leucocytosis and the polymorph infiltration of the liver found in infantile cirrhosis suggest an infection *B coli* have also been isolated from the urine of affected children, but may have no ætiological significance, they are found often enough in European children without cirrhosis Diet seems to play a part, 98% of cases are found in vegetarian families in which, after weaning, the child's staple food is rice A R Rich and J D Hamilton[3] claim to have produced cirrhosis in rabbits on a diet deficient in vitamin B, but their experiments are invalidated by the susceptibility of rabbits to coccidiosis, which favours the development of fibrotic changes D P Earle and J Victor[4] have induced cirrhosis in rats by feeding them with cystine and have shown that choline given at the same time prevents the cirrhotic changes Choline also prevents fatty infiltration of the liver, which according to modern workers precedes the development of cirrhosis Other workers have found diplococci in the liver in cases of Hanot's cirrhosis, and Weaver produced proliferation of the bile ducts after injecting guineapigs with *B coli* It seems probable, from the evidence, that more than two factors are at work in infantile cirrhosis Dried milk preparations have certainly done much to reduce the incidence in India

Dr William Lyle has been returned unopposed as one of the representatives in the Northern Ireland parliament of the Queen's University, Belfast

DIPHTHERIA IMMUNISATION —Of the 1440 local authorities in England and Wales 685 have reported to the Ministry of Health that up to the end of last June half or more of their children aged 5–15 had been protected But only 247 authorities were able to report that at least half the children in the age group 1–5 had been inoculated

HEALTH OF THE CIVIL DEFENCE WORKER

THE MOH'S OPPORTUNITY

LORD HORDER G C V O, F R C P
CHAIRMAN OF CIVIL DEFENCE WORKERS HEALTH DEPARTMENT

THE winter ahead of us, with its perhaps critical phase of the war, presents a new health problem of great importance—how to keep fit the large standing army on the Home Front which civil defence has mobilised. That this army must maintain its health level at all costs is obvious, but it must be recognised that, unlike the other arms of HM Forces, there is no coordinated or official system of medical oversight and welfare by which this may be done. The CD army, an "army of amateurs," was recruited without any routine medical check in the first instance and has been totally untrained for those extremes of mental and physical endurance that it has been called upon without warning, to bear during the Battle of Britain and ever since all over the British Isles. Despite these handicaps, after extremes of terror and horror, their service switched to endless waiting and with many fretful reorganisations, these men and women of middle age have proved themselves "good stuff" and worthy of all the support they can be given.

* * *

While in theory the health of the great regiment of CD workers remains the responsibility of the general practitioner, who is usually the panel doctor, the semi-regmented state of these citizens actually causes to fall upon the already overburdened MOH and his staff a great deal of this vital medical oversight. It was upon the MOH that much of the work of recruitment and initial training of a section of the CD workers devolved and it is the MOH who now has to face the psychological factor of tension in waiting allied to its paradoxical opposite, extreme boredom. I have long been an advocate for increases in the MOH's medical staff. Only in that way can he fulfil these important new functions. These include checking up the health of all CD personnel under his control. The officers in charge of personnel should know their men and women and should have their confidence. This puts them into the position of being able to report to the MOH on each individual as necessary. In the early stage of some disability or other this cooperation will not only assist the individual, it will save the service from wastage of time and money. Even more important, it will save the morale of the post from insidious disaffection and sometimes also from the contagion of malingering as the only relief from an intolerable situation. If the MOH, the key man, is not prepared to exercise this function, his colleague the controller and himself will be left inevitably to struggle with depleted posts and with general dissatisfaction amongst those whom he has not sufficiently cared for nor controlled.

Now is the time to take stock of the measures that are available to the controller on the advice of the MOH for the prevention of winter sickness amongst his personnel and here I can become constructive, and not merely admonitory, in my comments. It has been my privilege to be associated as its chairman since its start with one of the most progressive of the war-time activities of the War Organisation of the Red Cross and St John, the newest department of this great body, the Civil Defence Workers Health Department. The aim of this young and vigorous branch is to prevent illness, to avert breakdown and to assist CD personnel of all services and both sexes to be and to keep "fighting fit." To achieve this end two facilities are offered free to selected cases first, recuperative rest in rest-houses and in private hospitality, for men and women who can be saved by a brief, carefully arranged rest, secondly, and more important at this moment, convalescent treatment in homes run by the Red Cross and St John for men and women either after hospital treatment or if in the opinion of their doctors they would benefit from such treatment prior to succumbing to "illness" when it threatens them. This work has been going on steadily for some fifteen months it has spread all over England and Wales, the machinery is so simple, the cooperation with the authorities interested so complete and so easy that it has succeeded even beyond our own expectations wherever it has been set in action.

* * *

It is essential that medical officers, burdened as they are by so many cares, should realise that here is a service that will involve them personally in no new administration nor the scheme-making authorities in any expenditure, and that will militate against absenteeism and malingering as nothing yet has done. It does, however, entail the modern outlook, the preventive-medicine viewpoint, and it does entail a shouldering, by the MOH concerned, of his responsibility towards the personnel in his charge. His only additional duty is to acquaint himself with the facilities offered and to see that his officers make themselves cognisant of these facilities and make it easy for their men and women to avail themselves of them.

In a certain city in the Midlands, noted for its progressive viewpoint the use of this service of convalescent home accommodation was put to the director of this department very much better than we have yet put it for ourselves. An official declared that if it be necessary—as it most undoubtedly is—to rest and refit machinery, the same necessity exists to rest and refit the human beings whom we are running quite as hard as we run machines and with a great deal less care than we give to the machines. We "service" our machines because they cost money but we are apparently content to permit our human material to "overrun" until it crashes and then we are usually content to let it somehow refit itself during the 13 weeks that, at this stage of "disgruntled" ill health, it bitterly regards as due to it from an authority that did nothing to prevent the crash.

This department, with its careful check-up of each individual applicant, its allocation of each patient to suitable accommodation and its essential human and personal approach to the problem of each worker, constitutes a powerful ally to the MOH. In London (Region 5) this machinery has been perfected. The man sickening for a preventable ailment or the post-illness case is sent, with a leave permit and his own doctor's certificate, to 6, Cadogan Square, or, if he cannot come in person, his case is referred by letter with the necessary two papers. That is all. Thereafter the department's skilled staff takes over if the case can be dealt with suitably by the means at its command, he is at once allocated to a suitable convalescent home. The whole process takes some 48 hours normally, but cases can be got away in less, and there is no charge of any sort. That week, that fortnight, spent under skilled and careful supervision may, and nearly always does achieve one of two things. *the potential* patient is saved a serious illness if he has been taken as a preventive case, or, if he needs recuperation after an illness or injury, he returns fit for service in a very much shorter time than if he had returned to his post only to go sick again. Nor is the intangible, the psychological, side forgotten sick men do not get well if they worry, so the assistance board has seconded an officer to see, in confidence, each patient and make sure that that man or woman is, as far as possible, free from financial or private worry about pay or dependants.

* * *

There is another, very important point, and it is well to face it civil defence personnel are often disgruntled—"browned off" is a term often used of, and by, them. The very fact that they are taken into convalescent homes on an equality with HM Forces, that these men and women are treated as soldiers (which they are) and afforded facilities shared by sailors, soldiers and airmen (and women of the services) makes for esprit de corps and for a feeling of fellowship in the war effort that nothing else can give them at this time. This convalescent accommodation is given to civil defence by arrangement with the Ministry of Health, this work has not only the blessing but the active help of both the Ministry of Health and the Ministry of Home Security and also of all regional commissioners and other CD authorities concerned. The department uses accommodation in 33 convalescent homes in 8 regions of England and Wales and has some 13 rest-houses for recuperative rest. It is being used increasingly by progressive medical officers everywhere.

I end as I began, by pleading with medical officers who have the great responsibility for the Home Front this winter, that they look to all sources of help for the health of their depleted and middle-aged civil defence personnel. A good average level of health is the most potent factor in morale and, as far as the individuals *in ARP* services are concerned, the fact that their local authority does look to their welfare and does take the trouble to explore and make known such services as I have here described, *health* services and not *illness* services, may make the vital difference in their winter's work

A high sickness rate is avoidable A bad absentee record, a bad malingering record, a bad sickness curve is a personal reproach to the MOH concerned if he has not explored all the means of preventing these things that are now ready to his hand, and has not activated the controller to make the utmost use of them

In England Now

A Running Commentary by Peripatetic Correspondents

Sanderson is dead He had spent two and a half years in our hospital, first with surgical and then with pulmonary tubercle We see so few such cases that the PM was crowded , it made you wonder how the surgeons and physicians had kept life so long in his exsuccous corpse It made me think too of the only other adult I ever saw dead of tuberculosis She was a Navaho Indian, one of those fifty thousand pure-bred Indians who live in the hot dry summers and snow-cold winters of Arizona and New Mexico Just before she died they had a nine-day night chant for her The Indians came riding in on their brown horses, and the deer-eyed women cooked for them In the evenings and through the night the Singers went through the long songs of the Navaho

With dew about your feet may you walk,
With bright clouds above your head may you walk,
At dawn, in happiness may you walk,
In the beauty of evening may you walk,
In old age walking the beautiful trail

up to the final fourfold repetition of

In beauty it is finished

Outside, through the open door of the cup-shaped hogan, she could see the innumerable stars of the Arizona night Round her were all her friends, each one intent on thoughts of happiness and beauty for her, so that the thoughts might somehow make her feel well The gods came to visit her—Dawn-boy and Pollen-girl, Nayemezgani the Slayer of Enemy Monsters By day she saw the sunlight on the red and golden rocks Soon after the Singing, she died It seems that civilisation has taught us to postpone death , but both life and death are enfeebled in the process

* * *

To any doctor of my seniority who finds doctoring has lost its charm I can recommend the experience that has come my way in the course of war service As the resident surgeon at an EMS hospital with no houseman, I have resumed the rôle of casualty house-surgeon in which I started professional life 35 years ago In that period there has been sandwiched a slab of active service in the old war between slices of general practice During the nine months of the blitz we admitted from the surrounding densely populated area a large number of air-raid casualties by day and particularly by night, which involved a great deal of somewhat elementary surgery in intensive doses , on the whole the results were satisfactory Since the raids stopped the hospital has become the rendezvous of the local outpatients, who find it too expensive and time-consuming to go to the nearest large general teaching hospital, whereas there is not nearly so long to wait for attention here Having a small X-ray machine, it has been possible to deal with fractures Including those seen in raid cases there have been some 180, of which the most numerous were Colles', ribs, skull, humerus and tibia, in that order, though we have had examples of some of the rarer kinds such as scapula, scaphoid of hand and foot, cuneiform, and transverse process of lumbar vertebræ Like all hospitals we have seen innumerable cases of scabies, and have been fortunate in being able to refer them for treatment to a centre established by the progressive and efficient local authority, which incidentally uses part of the hospital premises for its diphtheria-inoculation clinic Another skin condition that seems to give rise to much lay apprehension is the local œdema produced by mosquito bites, the patient's fear being that the swelling indicates serious blood-poisoning , a little lead lotion and a lot of reassurance rapidly cures both bite and fear Minor burns seem to do best if the raw lesion is sprinkled with sulphanilamide powder under a dressing of sterile soft paraffin When healthy granulations are established, scarlet red ointment rapidly epithelialises the s with a minimum of scarring

The local dogs seem to be very irritable or else the children tease them indiscreetly, and the traditional fear of hydrophobia leads to the bringing in of the most trivial of scratches caused by their teeth There was one dog that recognised the uniform but not the sex of a very indignant postwoman Only one case gave rise to any surgical anxiety and that cleared up when treated as an ordinary septic wound Two popular diversions among the hobbledehoys of the neighbourhood are hair growing and stone-throwing The combination gives rise to awkward moments when a patch of scalp has to be shaved to get at and treat the triradiate, "Isle-of-Man," lacerations that occur when the aim is good enough to score a direct hit The workers at the near-by shell factory have a habit of getting their feet in the way of rolling shell cases which are of the larger calibres, and there are in consequence many bruised feet, some with fractures of metatarsal or phalanges

One serious reflection emerges from seeing many children at all hours of the day and night with little or nothing the matter with them but about whom the mother is scared, through ignorance A favourite diagnosis of the grandmother is convulsions, arrived at by noticing for the first time the natural phenomenon of eye-rolling under the closed lids during sleep There is no doubt that housecraft and mothercraft should be essential subjects for inclusion in the instruction at elementary and indeed all schools for adolescent girls From the angle of the improvement of the health of the coming nation these subjects seem much more important than shorthand or typewriting I commend this thought to those who are planning the curriculum for the extra years when the school age is extended

* * *

English manners have long been a mystery to the foreigner André Maurois, for example, says that in France it is ill-mannered to let a conversation die, whereas in England if you say nothing for two or three years people begin to think what a nice quiet fellow that Frenchman is All the same, as manners go ours are good, even if on absolute as well as relative grounds they can fairly be called mysterious The best example of our national manners I have ever seen was displayed under my nose last Saturday, and I am proud to say I contributed my quota to the whole The carriage was full, the train had begun to move, when the door opened and in leapt three spirited WAAFs The largest made straight for the opposite door of the carriage and tried to open it The train was now moving at 20–30 m p h (full out on our line) and the soldier sitting in the corner said with some (but not much) astonishment "Do you want to open the door?" "Yes," replied the WAAF in firm North Country accents, "Ah do" Nobody said a word We watched with keen but silent interest as the soldier drew back the stiff latch for her and pushed the door open "Oh," said the WAAF, unshaken "I thought it were a corridor train You can shut it up again" Silently the soldier shut the door , and my national manners which had stood up so well to the strain suddenly deserted me "That was uncommonly obliging of you," I said to the soldier "Well," he answered reasonably, "I thought perhaps she wanted to commit suicide"

* * *

Among casualties admitted to a South Coast hospital during a recent air-raid was a man with an injured thigh There was what looked like a wound of entry beneath which a sharp-pointed object could be felt When the injury occurred the raiders had dropped all their bombs on a neighbouring town and were speeding home with their guns blazing The object therefore was not a bomb fragment and was thought probably to be part of a fractured femur X rays however disclosed an unexploded aeroplane-cannon shell 8 by 2 cm with the blunt end lying deeply and the apex tapering to a fine point The wound was dressed and the limb splinted The Bomb Disposal Unit was consulted and the officer in charge visited the hospital and saw the radiograms The shell he identified as of the armour-piercing variety which explodes on impact, and there were dark hints of a subvariety whose explosion is delayed Removal was an obvious necessity, danger or no danger Naturally the patient was left in blissful ignorance The others in full knowledge of the facts got to work without fuss or hesitation. There was none of the Gallic theatrical technique adopted, as quoted in the *Lancet* of Oct. 24 (p. 501) from the *Siecle Médical*, for extraction of a mere explosive bullet. Within half an hour of leaving the ward the patient was back in bed. As the Chairman said two days later at the hospital's annual bazaar, "safely and successfully our surgeon had performed the most delicate and the most dangerous operation of his career." When the operation was nearing completion the face of an assistant surgeon was seen at the theatre door. Asked what the dickens he wanted he replied, "Only to know what my prospects are of promotion to the senior staff." The Chairman informed his audience that the tenets of his profession forbade him to disclose the surgeon's name. Subsequently, having incorrectly been himself designated in the press a surgeon, he has received embarrassing congratulations on his courage and skill, and on his surpassing modesty in not disclosing his own name.

* * *

"Foosh!" said the Surgeon, throwing the latest *Lancet* indignantly on the sofa, "'In England Now,' why not 'In Britain Now'?" "Well," said the Physician mildly, "it's mainly about England, you know. Aren't you Scotch a little too touchy about this?" Despite his mild manner the Physician was well aware that he was dangling a red rag, and our shaggy Highland bull responded as ever to the challenge. He seemed to have realised, however, that his usual explosive tactics were being drawn out for the tonic effect they always had on our little community, and adopted a new line. "Please, do not misunderstand me. I like the English, I admire the English, but I'm not an Englishman, and am quite content not to be taken for one. I am British, and very proud of it. This is a matter on which we feel deeply. There are many differences between the two peoples, whether you like it or not. I am reminded how in my Alma Mater there was a laureation of a distinguished Virginian scientist. The University organist used to play some appropriate tune when each honorary graduand was led up to the Chancellor, and this time he chose an American tune all right, but it was 'Marching Through Georgia,' and it took a deal of explanation later to convince him of his gaffe. Fortunately the Virginian professor, like most Scots, had sufficient sense of humour to appreciate the situation, but the lesson I am trying to drive home is the failure of the organist, and of you people in parallel case, to appreciate that there *is* a situation." The Physician felt it was up to him to return the ball. "But what have you to complain about really? After all, you chaps come down here from your native fastnesses and take all the best ..." "Jobs, I know!" interrupted the Surgeon. "Now that is where you English show how much cleverer you are than we. You trail out the hoary tale of the Scot who only met the 'heids o' the departments,' and hypnotise the unsophisticated Caledonian into believing that he *does* get the best jobs. The fact is that Scots get plenty of the second-best jobs, not because they are as clever as the English but because they are accustomed to work harder, and all the real plums you keep to yourselves, very sensibly, I must admit. Scotland is a poor country, and when any of her sons manages to get a post at £1000 a year he is convinced that he has reached the dizzy pinnacles of real wealth, and is completely satisfied with his position. The true trouble about the Scots is that they are not ambitious enough and are too modest." From this knock-out blow the Physician bravely tried to rally, after being down for at least nine seconds. "But take for example, Sir ..." "No, there is no use citing a few exceptional individuals to prove a general case," said the Scot. "The fact remains my people are too modest, lacking in ambition, and not nearly as clever as you who are able to hold better jobs with far less effort. We have our good points, but we don't blow our own trumpet enough." This stopped the Physician completely, but the Obstetrician gently interjected, "That is because it is not a *British* habit." The Surgeon looked up. "Thanks," he said, "that's better. But I wish that the *Lancet* would have 'In Britain Now.'"

"I will write to the Editor about it," said the Obstetrician.

* * *

Dicta from donors: "I absolutely insist that my blood be used for the Air Force only."—"I hope my blood is not going to be made into that plasma stuff."

MEDICINE AND THE LAW

Fatal Dose of Paraldehyde

AN inquest at Swindon last month investigated another fatal case of overdose of an anæsthetic before operation. The patient, a boy suffering from catarrh, was sent into hospital. X-ray examination indicated a risk of deafness; an operation for widening the nasal passage was advised. The assistant medical officer wrote out clear directions for the sister; the anæsthetic was to be half a drachm of paraldehyde per stone body-weight plus half a drachm. The sister, a state-registered nurse who had qualified in 1929, retired on her marriage in 1934, and returned to nursing in 1940, was described as careful and competent. Unfortunately she read "ounces" for "drachms." It seemed that she had no previous experience of administering paraldehyde. There was evidence that she had been worried at the time by bad news of the illness of her husband and had applied for leave to go to him, but was asked to wait a few days as the hospital was so short of trained nurses.

The anæsthetic was given and the operation was skilfully performed. The patient was brought back from the theatre at 1 P.M. His failure to recover consciousness, and other symptoms, led to the discovery of the mistake. All possible remedies were applied. After telephone messages to the Royal Infirmary at Bristol an iron lung was procured. It could not arrive till 9 P.M.; when it came there were difficulties in fixing it; it had not been used before and the leads were not correct. Eventually the boy was placed in the iron lung, but his heart stopped beating at about 10.30. In answer to questions the county pathologist (who carried out the post-mortem examination) expressed the opinion that, if an iron lung had been available as soon as it was realised that a heavy overdose had been given, the boy might have been kept alive. The boy's father complained that replies to inquiries made while the patient was lying gravely ill were evasive and that he had not been sent for to see his son on his deathbed. The coroner drew attention to the need for doctors to give clear directions about dosage, to the desirability of relatives being given every opportunity in such cases, and to the hope that some day iron lungs would be provided for all hospitals. He returned a verdict of death from misadventure.

Medicine or Drink?

The recent decision about Hall's Wine (Nairne v. Stephen Smith & Co., see *Times*, Oct. 15) illustrates the drafting difficulties encountered in framing the Pharmacy and Medicines Act 1941. Besides abolishing the medicine duties and prohibiting the advertisement of remedies for Bright's disease, diabetes, epilepsy, tuberculosis and other specified illnesses the statute at last required the disclosure, both qualitative and quantitative, of the composition of medicines, while restricting the sale of medicines by unauthorised persons. This reform was in part delayed by apprehensions of the awkwardness of defining what is a "medicine." Would the statutory definition, for instance, cover or exclude cold cream or beef-tea or lime-juice or the so-called tonic wines? The draftsman, who had simultaneously to maintain a second front against intermittent pressure from the herbalists, eventually had recourse to the phrase "substance recommended as a medicine." This phrase he defined in section 17 as a substance which is referred to on the wrapper, container, label or accompanying document or in any placard or advertisement

> "in terms which are calculated to lead to the use of the substance for the prevention or treatment of any ailment, infirmity or injury affecting the human body, not being terms which give a definite indication that the substance is intended to be used as ... a food or drink and not as ... a medicine."

Asked to define an elephant, a little boy once confessed his inability but announced that he knew one when he saw it. The law occasionally declines to define its elephants; it refused to define the crucial word "uniform" in 1936, when passing the Public Order Act to control the displays of blackshirts, greenshirts and redshirts, and threw upon the magistrate the responsibility for recognising uniform when he saw it. Normally Parliament feels obliged to attempt explanatory definitions even though the resultant language be elephantine

Thus the definition clause in section 17 of the Pharmacy and Medicines Act left the court the question whether Hall's Wine was or was not a "substance recommended as a medicine", if it was so recommended, did it nevertheless still escape the requirement of the disclosure of its composition on the ground that it was intended to be used as a drink? And if it was so intended, was there a "definite indication" of the intention?

The litigation was in form a domestic quarrel The plaintiffs were shareholders in the defendant company (Stephen Smith and Co) which is the proprietor of Hall's Wine They asked the judge to declare that Hall's Wine was "a substance recommended as a medicine" within section 17 and to grant an injunction restraining the company from selling it without exhibiting the "appropriate "designation" and the "appropriate quantitative particulars" required by section 11 The company told the court that it did not desire to have the article classified as a medicine, the act, it argued, did not insist upon any specific statement that a drink was only a drink and not a medicine, it merely required a "definite indication", the word "wine" by itself definitely indicated a drink and not a medicine The Pharmaceutical Society, which has a statutory duty to enforce section 11, was also a party to the proceedings Its counsel explained that the act was passed to enable the public to know what it was buying Hall's Wine was recommended on its label or wrapper as a "tonic beverage" ("the leading tonic beverage for giving new life in all run-down conditions"), it was claimed to possess "approved tonic and nutritive elements" ("for fifty years doctors have recommended Hall's Wine for its assistance in convalescence after serious illness") "Tonic," observed the Pharmaceutical Society, is declared by the Oxford dictionary to be a well-known medical term, "tonic beverage" suggested something more than a mere drink, the rest of the label clearly implied something medicinal

Mr Justice Atkinson accepted this contention He was prepared to regard "run-down conditions" as an "ailment" within the statutory definition, the label meant that the "substance" should be used to treat an ailment Hall's Wine was therefore within the first part of the definition, but was it exempted from the act as being a drink? He ruled that it was not, he found no "definite indication" that it was to be taken as a drink and not as a medicine He granted an injunction in the terms asked for by the plaintiffs but suspended its operation for 28 days or pending steps to be taken for an appeal

SCLERODERMIFORM SARCOID

THE term sarcoid is applied to a group of neoplasms of the skin or subcutaneous tissue, in appearance resembling connective tissue and of low malignancy They *may be single or multiple* Their ætiology is unknown, but it is thought that they may be related to tuberculosis, syphilis or other chronic infection The following case, reported by A Fonseca (*Amatus Lusitanus, Lisbon,* 1942, **1**, 558) is an example of the multiple subcutaneous form A bricklayer aged 37 complained of nodules on the face, arms and trunk, present for about a year He had been treated in the past for gonorrhœa and for syphilis, the last antisyphilitic injections having been given, despite a negative Wassermann, 2 years previously during an acute respiratory affection He looked healthy and no evidence of organic disease was found on routine examination The nodules lay in the subcutaneous tissue, were of uniformly hard consistence and movable over the deeper tissues, and were neither painful nor tender No signs of inflammation or œdema were present X-ray examination showed no abnormality of the cranial or facial bones, peribronchitis and moniliform bronchiectasis were present in both lungs, suggesting a syphilitic condition The Mantoux, Kahn and Wassermann reactions were negative Biopsy showed a diffuse infiltration of the subcutaneous fatty tissue by connective tissue cells, lymphocytes and epithelioid cells, with much fibrous tissue The small blood-vessels were compressed and the lumen almost obliterated In some parts the arrangement was follicular, somewhat resembling a tuberculous nodule The overlying skin was unaffected

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

Miss Horsbrugh, in reply to a question reported a large increase in the number of nurses in service But sanatorium wards in some places can still not be opened and there is a restriction of cases admissible to infectious diseases hospitals It is not only a question of pay but of conditions and while many trained nurses have come back to the profession there are others doing munition work or office work It would be advisable to check the conditions of service in some of the smaller institutions where women complain of being treated as substitute domestic servants instead of being given opportunities of training And the Services are of course attractive to adventurous young people The Minister of Health was also subjected to a light bombardment on the supply of doctors for pensions appeal tribunals, and a question from Sir Ernest Graham-Little drew a statement of policy on not appointing a nutrition council as recently advocated because the Minister considered existing agencies were sufficient As soon as the House had gone into Committee of Supply to consider a vote of another £1000 million for war purposes the chairman of committee was asked for a ruling whether the question of pensions appeal tribunals could be deleted The answer was no But this and the previous questioning are only part of a preparatory barrage to an attack which will develop later in the month of November

The Minister of Pensions was also attacked on the refusal of Service pensions for technical reasons Mr Vernon Bartlett, who knows a good deal about publicity, said that he wondered if the Minister was not the worst enemy the Minister of Information had in this country *because there is not a town and hardly a village where* some pension case is not a cause of rankling discontent Almost the whole debate was on this key and the Minister is getting an unfortunate name for stinginess despite his habit of "stating emphatically" that he is doing his job *properly* Unhappily the medical staff of the Ministry get criticised for actions for which they have no responsibility

The last day of the last series of sittings, however, included a discussion on industrial rehabilitation which showed the *medical profession* in a more sympathetic light The work done at Mansfield to which I have made previous reference was described by Mr Bernard Taylor, the miner MP for that division, and the Parliamentary Secretary to the Minister of Labour gave a wide significance to the debate when he included all accidents and diseases leading to disability Mr Tomlinson also stressed the importance of the social and industrial expert's work in connexion with rehabilitation The facts were of course the same before the war as they are *now, but the evaluation of man-power* was different It is now so precious that much can be done by consent that before would have caused violent controversy Mr Tomlinson urged us to use all the brains and ingenuity we have to devise machinery and working conditions to prevent accident and disease

It is significant that the last debate on this closing day was on the spiritual side of the war Lord Halifax, Ambassador to the USA, and Sir Samuel Hoare, Ambassador to Spain, had spoken of the issues of the war as "the establishment of Christian civilisation and Christian brotherhood" Lord Winterton, a member of the Church of England, but with a far-reaching knowledge of the Moslem world, and Mr Sorensen, the pastor of a Christian congregation, both wanted this definition widened Lord Winterton spoke of the need to appeal to world religious and moral opinion and not to any one creed or religion Mr Sorensen pointed out that among the United Nations fighting Hitlerism there are three non-Christians to every Christian and wanted us not to label all the virtues Christian William Hickey, otherwise Mr Tom Driberg, MP, supported Lord Winterton and the Under-Secretary of the Foreign Office endeavoured with some difficulty to speak clearly on matters of such deep concern but agreed that whatever we are, Christians, Moslems, Jews, Atheists or Rationalists—because Russia comes in—"we are *fighting for* the same things and

FROM THE PRESS GALLERY

Industrial Rehabilitation

AT present the injured workman only receives compensation for loss of earning and nothing towards the cost of refitting himself to take his place as an economic unit in society In opening the debate on Oct 22 in the Commons Mr R J TAYLOR urged that this rehabilitation was rightly the responsibility of the nation He paid a tribute to the work done at the Mansfield centre, specially commending the absence of hospital atmosphere Mr BERNARD TAYLOR, who proudly claimed to come from the home and hub of rehabilitation, said that the foundation for recovery was laid at the fracture clinic but at the rehabilitation centre healing became an art which expressed itself in broken men made fit to re-enter industry It was important he held to remove the feeling of insecurity from the minds of the men, to limit the size of the centre to about 60 patients, and to insist that it be residential Mr DAVID ADAMS welcomed rehabilitation as a new science which would be a heritage to industry. Mr GEORGE GRIFFITHS, a Labour MP contrasted the emptiness of the opposite benches with their fullness during the debate on wages Mr G TOMLINSON, who *replied for the Ministry of Labour* widened *the scope of* the discussion to include all diseases which led to disability and the many accidents which occurred outside industry A skeleton service already existed in the Emergency Hospitals Scheme Many orthopædic centres had been established in England and Scotland with workshops and with facilities for massage, physical training and occupation therapy Other hospitals had been earmarked for fracture cases and the Ministry of Pensions was doing wonderful work at Roehampton The Minister of Labour had only introduced his interim scheme in October of last year and it might be that a greater scheme would emerge from it After physical rehabilitation came training and resettlement, and the effect on the patient of the first interview in hospital which held out the prospect of return to some kind of work was striking At first the scheme had been confined to training people for the war effort but it now covered all types of industry Up to the end of August over 41,000 people had been interviewed, mostly with war injuries, but some with prewar disablements About 29 000 had found work, but he would not like to say that all had been placed in positions where their injuries were taken into consideration, and at the end of the war some might have to be retrained Of the 600 blind people interviewed 200 had been found jobs—many in engineering shops—not previously regarded as suitable for the sightless Two centres, at Leatherhead and Exeter, previously supported by voluntary contribution, had been taken over, where very badly disabled people were trained or treated Grants were also being made to undertakings employing the severely disabled Mr Tomlinson ended by urging that we should not lose sight of the need to prevent accidents while taking every step to make rehabilitation a reality

QUESTION TIME

A Nutrition Council

SIR ERNEST GRAHAM LITTLE asked the Parliamentary Secretary to the Ministry of Food whether he would consider the desirability of setting in motion the formation of a nutrition council, consisting of clinicians, laboratory workers and medical officers of health, as urged from many authoritative quarters —Mr E BROWN, Minister of Health, replied I have read with interest the recent expressions of opinion about possible developments in the realm of nutrition, and have had an opportunity of discussing them with my colleagues I am grateful for this opportunity of making clear the position of the Government in this matter Though the advocates of the establishment of a nutrition council appear to differ somewhat among themselves in regard both to methods and to objects, I am in a position to say that the main purposes which they appear to have in view are already secured by existing arrangements Technical investigation and research are adequately provided for through the Medical Research Council, the Agricultural Research Council and the Department of Scientific and Industrial Research A great volume of work is continuously in progress under the auspices of these bodies, and the first named comprises amongst its members and officers a number of scientists outside the medical profession, and from the outset much valuable research on nutritional problems has been conducted on its behalf The application to current problems of the results of scientific investigation is primarily the responsibility of the health departments, to whom the Ministry of Food and the agricultural departments look for guidance in nutritional matters when framing their programmes of production import and distribution of foodstuffs Coördination of the policies of the various ministries concerned is fully provided for by appropriate interdepartmental machinery The Allied Governments last year appointed an Inter Allied Committee to prepare estimates of post war relief requirements, and I understand that this committee has already arranged for a subcommittee of Allied nutrition experts to examine the estimates from the nutritional standpoint

Advisers to the Food Ministry

Mr W MABANE, replying to Sir E Graham Little said that the scientific adviser s division of the Ministry of Food consists of the scientific adviser, the deputy scientific adviser and seven scientific assistants, one of whom is on loan to the British Food Mission in North America Liaison between this division and the scientific committee on food policy is maintained by the attendance of the ministry s scientific adviser by invitation as *an observer* when required at meetings of the committee The scientific committee on food policy consists of ten members who are experts in science, agriculture or economics. The chairman of the committee is Sir *Henry Dale* The last meeting of the committee took place on Feb 4, 1942

Discharged RAMC Doctors

SIR JAMES GRIGG informed Major J MILNER that about 800 qualified medical men have left the Army during the present war —Major MILNER Is it not the fact that many of these medical men were quite suitable for utilisation in other capacities in the Army, and that they are all qualified medical men who have been removed from the Army, or have received their discharge, or something of that sort ?—Sir J GRIGG More than half of them have been invalided out

Doctors for Pensions Appeal Tribunals

Major MILNER asked the Minister of Health whether he could, if required, provide or make available a maximum of 50 *medical men* for the staffing of pensions appeal tribunals, either permanently or on the understanding that they could be released on short notice if urgently required for other purposes —Miss HORSBRUGH The Minister is advised that the pressure on the services of medical men is so severe at the present time that it would be difficult to supply those suitably qualified for this work in the numbers indicated It must be remembered that any new obligation imposed upon the medical profession in war conditions would prejudicially affect other services —Major MILNER May we take it that though it is difficult, it is not impossible ?—Sir FRANCIS FREMANTLE Is proper attention being given to the possibility of employing men who are discharged from high positions in different Services, who are men of great experience and could be used for this kind of work ?—Miss HORSBRUGH Yes —Dr GUEST Are not a certain number of medical men in the Services retired on account of age, or on account of having held high rank for a certain period and are there not enough of these people fully to fill all the requirements of pensions appeal tribunal purposes ? Will the hon. lady take it from me that I know positively of, and that I can give her a list of people who would fill all these places ?—Miss HORSBRUGH I should be delighted to have that list

Shortage of Nurses

Mr R DE LA BERE asked the Minister of Health whether he was now in a position to make a statement regarding the Government's proposals for securing an increased supply of trained nurses , and the Government's proposals for ensuring a better standard of livelihood for those so engaged —Miss HORSBRUGH replied Proposals for securing a better distribution of certain nurses, after discussion with the Minister of Labour and National Service, have now been put to representatives of the nurses and of their employers The Rushcliffe committee is considering the salaries of nurses —Mr DE LA BERE This has been going on for a very long time, but the nurses' standard of pay has not improved, and nurses are not becoming more numerous Something ought to be done now it is no good referring the matter to committees we want some practical action —Miss HORSBRUGH The number of nurses has increased very satisfactorily, though I am not entirely satisfied that we could not at this time be training another 2000 or 3000 women who wish to become trained nurses in the future We could also do with another 10,000 nurses throughout the country There has also been an interim increase in salaries pending the result of this committee of inquiry.

Mr F MESSER Is it not a fact that the increase is mainly in student nurses and there are many trained nurses who will not come back into the profession because they are better paid outside ?—Miss HORSBRUGH No, there has been an increase in trained nurses as well as in student nurses I think at present nearly all the trained nurses in the country are working If there are any who can be released from other jobs I shall be glad to hear of them —Mr DE LA BÈRE The pay is quite inadequate —Dr SUMMERSKILL In spite of the increase is it not a fact that we have not been able to open certain sanatoria because of the shortage of nurses ?—Miss HORSBRUGH Yes, but we are arranging for a better distribution of nurses We have to have a ratio of trained nurses and nursing auxiliaries One of the difficulties has been to get the right distribution.

Maternity Accommodation in London

Dr SUMMERSKILL asked the Minister whether, in view of the inadequate accommodation for maternity cases in London, he proposed to take any action in the matter —Mr E BROWN replied The accommodation for London mothers includes in addition to the beds available in London those available at some 100 emergency maternity homes which were established in the reception areas The adequacy of the provision in London has recently been under discussion between officers of my department and of the London County Council Additional beds are being provided but the number which can be brought into use depends primarily on the number of trained staff who can be made available I have framed proposals with a view to ensuring that more of the women qualifying as midwives will undertake to practise as midwives, and after discussion with the Minister of Labour I am in consultation with representatives of employers and employed on this question —Dr SUMMERSKILL Is the Minister aware that unless some action is taken in this matter the scarcity will be reflected in maternal mortality figures next year ?—Mr BROWN I am quite aware of the importance of the matter —Mr MESSER Is the Minister aware that the Central Midwives Board has issued a report in which it is stated that there is no shortage of midwives, but that the midwives are not doing the work ?—Mr BROWN That is the real problem A number of trained and qualified women are not doing the work

Industrial Dermatitis

The number of cases of industrial dermatitis in 1941 and 1940 were 7291 and 4744, respectively A total for this year is not available (Mr E BEVIN replying to Mr D N PRITT)

Service Men and Tuberculosis

Of the total number of men invalided out of the armed forces from the outbreak of war until the end of September last, 5 8% were discharged on account of tuberculosis, and of the claims made in respect of this disability rather more than 70% have been allowed (Sir W WOMERSLEY replying to Mr W H MAINWARING)

In answer to a further question Mr BEVIN stated that, according to sample statistics taken earlier this year, about 1% of recruits examined under the National Service Acts are rejected on account of pulmonary tuberculosis

Compulsory Notification of Venereal Disease

Mr P G BARSTOW asked the Minister of Health whether he proposed to take steps to compel compulsory notification of venereal disease, having regard to the increase of these diseases throughout the country —Mr BROWN replied I am considering what action can most appropriately be taken to check the spread of venereal disease but, at the present time, I doubt whether the particular suggestion made is best calculated to secure this object

Lieut -Colonel A P HENEAGE Has the Minister's attention been called to the difficulty of dealing with carriers of venereal disease, and will he consider strengthening the existing powers ?—Mr BROWN I am aware of the difficulties, and I have under urgent consideration the most effective methods of dealing with them —Lieut -Colonel HENEAGE Will the Minister say how long these inquiries will take, in view of the situation at the ports, and will he treat this problem as a plague and cease to surround it with mystery and laissez faire ?

Mr BROWN I am not talking about inquiries I am talking about urgent consideration, which means, of course, that I am thinking about action

Quota of Medical Students

Sir ERNEST GRAHAM-LITTLE asked the Minister upon what expert advice and upon what basis he carried out his allocation of quotas of admission of students to individual medical schools , and whether he made, or was prepared to make, such quota conditional on the acceptance by the school concerned of a certain proportion of women students —Mr E BROWN replied By arrangement with the Minister of Labour the quotas for male medical students at each medical school are based normally on the average yearly admissions over the three years 1936–39 A variation to suit local conditions is allowed on the advice of the chief medical officer of my department after considering the representations of the school authorities Quotas for women students are similarly fixed on the basis of the average admissions for the three years 1937–40 Where the number of male applicants falls short of the quota for men, no objection is raised to the admission of women to make up the deficiency if the school so desires I have no authority to take the course suggested in the second part of the question, which raises a separate issue of policy now under consideration by the Committee on Medical Schools

Calling Up the 18's

The Minister of Labour informed the House of Commons that on Oct 22 His Majesty had signed a further Proclamation as a result of which men who had reached the age of 18 up to that date would be liable to be called up under the National Service Acts Mr Bevin proposed to register on Nov 7 those who had reached the age of 18 between July 1 and Sept 30, they would be medically examined later in the month and called up as required, and many might expect to join in December He would consider what adjustments might be necessary in the national interest as regarded apprentices and students The reduction in the age of calling up did not affect the minimum age, namely 19, at which men called up to the army were posted for service abroad

---

"NIGHT WORK"

John Stuart Arey gives no key to his identity on the title page of his book (Eyre & Spottiswoode, 9s), though it seems certain from what he writes that he is a doctor or medical student, and possible that he is Welsh He tells the story of a night in hospital in 1940, a night in which two bombs and several incendiaries struck the hospital with the result, as the announcers say, that some damage was done and some lives lost His hospital and his characters, he asserts, are fictitional , but doctors and nurses and patients reading his book will know that there (and there only) he is talking rubbish We know this hospital, these people, the casual jokes, the routine which relentlessly brings order out of disaster We have worked or been treated there It was easy for him, perhaps, backed by our powerful associations, to evoke it all, even to the antiseptic smell agreeable to doctors, detestable to patients, which haunts the threshold of a hospital , but it was not at all easy to tell a violently dramatic story without ever forcing the drama on the reader's notice His purely objective style would be cold but for his insight into the characters he draws Only two seem alien to him Ackerly, the offensive little Lancastrian, and Whitley, the surgeon, whom Ackerly beautifully described as "full of gas and glory" It is as though Arey is puzzled to discover the human weaknesses over which these two had built their defences of aggression or complacence , and he cannot forgive them With the rest he is comprehending and at home, and takes his reader with him There is, for example, the old man at the beginning whom the nurse had wakened from a nightmare "But he was annoyed, and so he lay and groaned At times he belched, a windy, grieving sound " There are the rescue squad, digging out the medical registrar "Half an hour later the leader went into the tunnel himself, shifted a single piece of wood and sawed through another He looked back along the passage 'He'll come out now,' he said, conversationally " The book is built of short paragraphs flawlessly and inevitably placed To put it down half read is to have it tugging at the mind

Letters to the Editor

SULPHAPYRIDINE ANURIA

SIR,—This complication of chemotherapy is now widely recognised but it would appear that the principles of its treatment are sometimes incompletely understood Since recording my experience up to March 1941 (*Lancet*, 1941, ii, 272), I have met with further examples of hæmaturia and now have records of three patients successfully treated for anuria by ureteric catheterisation and lavage I would like to emphasise the following points

1 Anuria may develop in any adult receiving more than 5 g sulphapyridine daily if the amount of fluid retained is permitted to fall below 3000 c cm a day

2 Fluids must be pressed to *prevent* hæmaturia and anuria Once anuria has developed a high fluid intake is contra-indicated until the ureteric obstruction has been relieved by catheterisation This will be obvious to anyone who has studied the cystoscopic appearances at operation The intravenous administration of large quantities of fluid without first relieving the mechanical obstruction only increases the hydronephrosis and may lead to overloading of the circulatory system The latter is illustrated by the cases reported in your issue of Sept 26 Thus the case described by Carson and Smith (p 359) showed, at autopsy, œdema of the lower lobes and pleural effusion on both sides, while the case successfully treated by Benson and Percival (p 360) presented moist crepitations at the bases of both lungs before ureteric catheterisation

3 I believe, therefore, that ureteric catheterisation and lavage should be carried out not later than 12 hours from the onset of anuria It can be performed by a competent surgeon under local anæsthesia without detriment to the patient and will frequently prove a life-saving measure

It is now over nine months since a case of anuria developed in my department, in which an average of 250 g sulphapyridine is consumed daily I attribute this to the regime in force whereby each patient attends the four-hourly tablet parade with a pint mug of water in one hand and a specimen of his urine in the other Only if the urine is seen to be free from macroscopic blood are the tablets and water consumed there and then

S M LAIRD

ADEQUATE TREATMENT OF GONORRHŒA

SIR,—May I appeal to all practitioners to help the campaign against venereal diseases by using sulphonamides for the treatment of gonorrhœa in such ways as to make the patients non-infectious as quickly as possible, and to run the least possible risk of creating sulphonamide-resistant strains of gonococci ? From all parts of the country complaints are being received by the Ministry of Health that many practitioners start treating for gonorrhœa without first taking specimens for confirmation of the diagnosis, and give sulphonamides in quite inadequate dosage Failure to take specimens makes it very difficult whenever the symptoms have not abated or have relapsed, to decide if the original infection was or was not gonococcal—because gonococci may have been merely driven to ground by the remedy Inadequate dosage may abate the symptoms without eradicating the infection , thus by creating in the patient's mind the impression that he is cured it conduces to the spread of the disease

The evidence that it is possible to create sulphonamide-resistance in gonococci by under-dosage is strong and every effort should be made to avoid it because the spread of such strains throughout the country would take our antigonorrhœal measures back to the pre-sulphonamide era A timid dosage with sulphapyridine may perhaps be understandable when the infection is not life-endangering and the patient is ambulatory because of the toxic effects of this remedy but there is no reason for giving inadequate doses of sulphathiazole , and this drug is now available in sufficient amounts for the eradication of gonorrhœa from the community There is now good evidence that administration of 5 g of sulphathiazole on 2 successive days eradicates the disease, in males at least, in over 90% of cases , and 4 days treatment on the same lines affords still better results In neither case does such a dosage give rise to any undue proportion of toxic effects provided that the patient is made to drink plenty of water during chemotherapy

It requires only slight imagination to see the possibilities of this treatment from the point of view of the public health, if only all members of the profession will collaborate in exploiting it properly

L W HARRISON,
Adviser in Venereal Disease to the Ministry of Health

WOUNDS AND FLAVINES

SIR,—We have clinical evidence which confounds the impression formed during the last war and from recent experimental work (quoted in your leader of Oct 10) that healing is, or is likely to be, delayed through employment of the flavines Our evidence, which comes from the study of the healing of infected burns of 2nd and 3rd degree treated with proflavine sulphate, supplements the observations of Mitchell and Buttle that, " in 79 cases with bone, joint and soft tissue injuries no appreciable delay in healing has occurred "

Proflavine sulphate 0 4% in isotonic solution buffered to a pH of 6 2 in the water phase of an oil-in-water emulsion (see our paper in *Lancet*, 1942, i 347) does not impair the rate of healing of 2nd and 3rd degree burns, even when this flavine is applied continuously for 2–4 weeks or more, being renewed weekly We ascertained that from this depôt-dressing the concentration of proflavine constantly bathing the superficial granulations was 0 2%—half the maximum concentration in the depôt Infected 2nd degree burns of the area of a sheet of foolscap paper (650 sq cm) have been noted to heal in 14–21 days from the cessation of infection, or as in some cases, 20–36 days from the date of injury Areas of 3rd degree burning have taken longer, in proportion to the greater degree of damage All cases treated with proflavine sulphate have healed within what are to be regarded as " normal limits "—that is, within average times ascertained from parallel observations and measurements in comparable, non-infected cases of burns treated by tannic-acid and gentian-violet coagulation methods One example will illustrate this point

Injury —2nd degree burn of foot and leg (pail of boiling water)

Initial treatment —Compresses, 10% tannic acid and 1/1000 acriflavine

CASE A	CASE B
Stoker, aged 20	SBA (R) aged 19
Infected 5 days	Non infected
Treated Sat aq sod sulph , 2 days Proflavine emulsion, 19 days	Tan satisfactory throughout
Epithelialised by 26th day	Tan separated 30th day
Area burned 431 sq cm	Area burned 367 sq cm
Overall rate of healing (injury to epithelialisation)	Overall rate of healing (injury to separation of tan)
0 85 sq mm per mm circum per day	0 815 sq mm per mm circum per day

It will be recalled that Carrel and Hartmann (*J exp Med* 1916, 24, 429) noted that the rate of healing is proportional to the area involved—the larger the wound the greater the rate of cicatrisation Thus in some 2nd degree burns 650 sq cm or more in area we have found the healing edge advances inwards at the rate of 0 5 cm per day, the whole being healed in about 14–21 days—truly a remarkable " normal " rate of healing Now, if proflavine sulphate 0 2% were to exert an inhibitory action on fibroblastic activity and on epithelialisation in vivo, surely the best opportunity to observe this would be in the healing of such large areas where the rate is greatest Our series of measurements shows that this inhibition does not occur We have also observed that proflavine sulphate 0 2% has no inhibitory influence on the fibroblastic activity in exuberant granulations resulting from the hyperosmotic action of urea 5% In 3rd degree burns and " wounds " resulting from the excision of carbuncles, treated with proflavine-urea emulsions, no impairment of any kind has been noted

The solubility of proflavine sulphate in serum at 37° C is approximately 0 3%, the same as in saline (higher concentrations in serum produce flocculation) , this is a measure of the concentration probably obtaining in the soft tissues in the cases described by Mitchell and Buttle Our experience has been with the lesser concentration of 0 2%, but it seems reasonable to conclude from our complementary observations with actual measurements that in-vivo proflavine sulphate has no inhibitory action on fibroblastic activity and epithelialisation in the healing process

J F HEGGIE,
Aberdeen and Wakefield R M HEGGIE

CHALK IN BREAD

SIR —In the *Lancet* of June 27 I was surprised to see that Dr I Harris has quoted a letter from me, published in your columns on Nov 8 last year, in support of his contention that the addition of calcium to bread is not only unnecessary but actually harmful Dr Harris has completely misunderstood the purport of my letter All I wanted to point out was a simple scientific fact—namely that it is not possible to assess the Ca requirements of people from simple balance experiments unless the previous dietary history is known, since, for example with habitual low intakes, Ca balance may be attained at very low levels I did not mean to imply that this was normal or desirable In fact, of the cases I quoted from Owen, Irving and Lyall (*Acta med scand* 1940, **103**, 235) which were in balance on very low intakes, more than half had osteoporosis, as detected by X ray I deplore the implication that I consider that the Ca requirement of the adult is "very slight" In common with those qualified to judge, I consider that the Ca requirement of the normal adult individual is 0 8–1 g per day, and I support everything that Mr Bacharach says in the preceding letter with respect to the steps necessary in war-time to attain this intake

Department of Physiology,
University of Cape Town J T IRVING

FATE OF TRANSFUSED PLASMA

SIR,—The conception, put forward by Madden and Whipple and accepted by Beattie, that after transfusion plasma leaves the circulation and that plasma-proteins are stored in tissue cells, would seem acceptable only if osmotic forces are in play and the capillary walls permit the passage of protein If the plasma transfused is of the same osmotic pressure as the circulating blood, it is difficult to understand how even water can leave the blood-stream if the capillary wall is impermeable to protein—a conception dinned into us for years and years—how can protein pass ? Neither Madden and Whipple in their classic paper (1940), nor Whipple in his subsequent lecture (1942), nor Beattie either in his April paper (1942) or in his present one (*Lancet*, 1942, ii, 446) refer to these difficulties Perhaps Professor Beattie could enlighten us

Rugby R H PARAMORE

INSTRUCTION IN VACCINATION

SIR,—Now that medical students have to qualify much sooner than in peace-time, in order to play their part in the war-effort, it is more than ever necessary to excise redundant parts of the curriculum Most students, we are sure, feel that the six classes demanded by the official regulations in vaccinations are more than sufficient for the requisite training—and we think that some members of the staff would agree about this Surely two classes would be enough and the remainder of the time would be more profitably employed

BMA House A D BANGHAM,
Secretary, British Medical Students' Association

Obituary

DOUGLAS JAMES STIRLING ARMSTRONG

M B, B SC GLASG , D P H , MAJOR R A M C

WHEN the time comes for the story of the defence of Malta to be told the name of Douglas Armstrong, who lately died there, will have an honourable place He was the son of Dr W H Stirling Armstrong of Glasgow and graduated from Glasgow University in 1938 He joined the RAMC as a volunteer soon after the outbreak of war, and his appointment in January, 1941, as commanding officer of a field hygiene unit made him, at the age of 25, consultant and adviser in hygiene to the military garrison of Malta During the next eighteen months till his death, there were periods when, by enemy action, light, ventilation, water and sanitary facilities in large parts of the command were completely abolished Despite these tremendous difficulties, the hygiene of the garrison remained at the highest possible level

A G H , an RNVR colleague, recalls Armstrong's equanimity and perseverance when his headquarters were hit for the third time and almost completely destroyed, and how imperturbably he set about the work of reorganisation swiftly and efficiently To everything Armstrong did during these hectic eighteen months he added distinction and individuality, whether in painting water-colours of post-mortem lung-blast appearances, or investigating epidemic jaundice—a disease which may have caused his death

FRANK ROBINSON

M D MANC , D P H

Dr Frank Robinson, who died on Oct 5, was Cambridgeshire's first full-time medical officer He succeeded Sims Woodhead who had held the office in a consultative capacity during his tenure of the chair of pathology, and Robinson maintained this fruitful association of public-health and university work by acting as lecturer in sanitary law and administration in the university till the DPH courses at Cambridge were abandoned He had qualified in 1891 from Owens College, and as medical officer in one of Liverpool's poor-law institutions had early gained expert knowledge of both smallpox and typhus fever, the thesis for which he was awarded the MD in 1895 being a clinical study of 220 cases of smallpox From Liverpool he went to India as a plague medical officer to take his part in Haffkine's inoculation campaign On his return to England Robinson became assistant MO for the West Riding of Yorkshire and he held this post until he went to Cambridge where he was to work for twenty-six years Here he saw many changes in the public-health services, and had to administer many new developments, his successor testifies that at the end of his period of office Robinson left a smoothly working service which presented few difficulties But his interests extended far beyond his daily activities He presided over the Cambridge Rotary Club and served on many bodies doing voluntary medical work He was keenly interested in all the arts and was a musical performer of ability His collection of pottery was noteworthy, while his pioneer work for the Cambridge and county folk museum happily filled much of the leisure which retirement brought But the war had lately reharnessed him He was indefatigable as joint secretary of the local medical war committee and had lately been appointed by the Ministry of Health a consultant for the diagnosis of doubtful cases of typhus

GEORGE WASHINGTON BRAZIER-CREAGH

COLONEL AMS (RETD)

Colonel G W Brazier-Creagh, CB, CMG, died in London on Oct 10 in his eighty-fifth year He was named after his father George Washington Brazier-Creagh of Buttevant, and Creagh Castle, co Cork, and educated at Trinity College, Dublin, where he took his medical licence in 1880 A year later he was commissioned surgeon and shortly after his promotion to major in 1893 he conducted missions to Persia, where he made extensive explorations of little-known regions in Eastern Persia and Baluchistan and made possible the development of the Seistan-Nushki trade route For these services he was thanked by the government of India and for his work on the Punjab Frontier expedition he was awarded the medal with clasp At the end of 1898 he was seconded for extra-regimental service under the Pekin Syndicate which he accompanied through North China The South African war brought him to that country and he took part in the relief of Ladysmith and in such famous actions as Colenso, Spion Kop, Tugela Heights and

Pieters Hill Later he served in the Transvaal and on the Zulu frontier of Natal He was created CMG, awarded the Queen's medal with six clasps, and the King's medal with two clasps A colleague remembers how as a true horse-loving Irishman during the Natal operation in 1900 he sent a clear-the-line message announcing the winner of the Grand National, justifying this unorthodox urgency by saying it would cheer the troops He was made a lieut -colonel in 1901 and retired ten years later but served again in France all through the last war, when he was four times mentioned in dispatches and created CB

Notes and News

HEALTH OF AN ISLAND BASTION

DURING 1941 nearly half of Ceylon's six million inhabitants were treated for malaria—61,853 as inpatients and 2 860 890 at outdoor dispensaries—and 7113 of the 113 003 deaths that year were attributed to this disease Special mosquito surveys were undertaken for local authorities, but owing to the difficulty of obtaining equipment it was not possible to set up the proposed field laboratory Leprosy is another of Ceylon s problems which is being tackled with understanding and efficiency The old name of " leper asylum " has been changed by law to " leprosy hospital " and at the end of the year there were 1098 cases segregated in the island's two institutions A further 1213 cases attended the twenty-four clinics some for observation and some for treatment During the year 248 fresh cases were discovered, 10 among the children in the 112 schools which were inspected The nutrition division of the Bacteriological Institute has been seeking to meet wartime deficiencies and has had good results from red-palm oil and shark-liver oil as a substitute for cod-liver oil The war has not been allowed to interrupt the expansion of the maternity and child-welfare service for which there is a growing demand among the people Fifty additional midwives have been appointed for the country districts, and 24 new health centres and 5 maternity homes have been opened During the year 104 000 expectant mothers 116,000 infants and 108 000 preschool children came under the care of the service The quarantine department has an important place in Ceylon's preventive health services There are two camps in South India through which immigrants pass and where in 1941 for instance, nearly the whole of 3584 incoming estate labourers were treated for hookworm and vaccinated At Colombo the port authorities also vaccinated over 28 000 people many as a precaution against the one case of smallpox found aboard a ship which called at the port Of the outgoing passengers 258 were vaccinated at their own request

DENTAL EDUCATION AND THE STUDENT

BRITISH dental students have followed up their memorandum on the nation's dental services[1] with a study of the future of dentistry, of which part 1, on dental education, has now appeared[2] The joint planning committee of dental students, which is responsible for both publications, has now become a subcommittee of the British Dental Students' Association, founded last April The recommendations in the new memo represent the views of most of the dental students in the country, and follow lines which might be anticipated from the information in the first memo Students wish to see established a basic qualification in dentistry of uniform standard in all the dental schools of the kingdom , this they consider should be the degree of bachelor of dental surgery They suggest that present holders of the LDS should be allowed to enter for the BDS examination without further preliminary training Fees, they consider, should be the same at all schools and there should be plenty of state scholarships to encourage more young people to take up dentistry Schools should be provided with adequate full-time salaried staff and enough part-time instructors to provide about one demonstrator to six students Honorary staff should hold postgraduate qualifications and the hospital administrative body should be augmented by a committee on which house-surgeons and students would be represented They suggest that hours of work could be more vigorously enforced in most schools, and like medical students they find they learn more from clinical demonstrations and discussions than from any other method of teaching They are severe about the efforts of their lecturers, and suggest that lecturing should be the task of members of the salaried staff who have been trained to do it The suggestions that students should compile a case-book of the patients they have treated during training, and that there should be an interchange of final year students for three-month periods between schools both deserve serious attention They have drawn up one curriculum lasting 5½–6 years and another lasting 5 years, and make some suggestions about examinations which seem wise , for example, they propose that the practical examination in conservative dentistry should be held in two three-hour sessions, with several patients, in an attempt to eliminate luck as a factor They offer some general advice on the training of dental nurses among which is the rather vague proposal that they "should be instructed in the rudiments of nitrous oxide anæsthesia", and some much more concrete proposals that all medical students should be required to attend lectures and a practical course in giving nitrous oxide nasally and lectures on dental surgery, particularly on the relation of dental diseases to general health, and of systemic diseases to the mouth and teeth , on the ætiology, diagnosis and results of maleruption of teeth and on the diagnosis of caries, parodontal disease, alveolar abscess and other dental disorders

VIRTUE IN POTATOES

FOUR tons of potatoes have the calorie value of a ton of wheat This year, when home-grown potatoes look like being plentiful we shall have to see how far they can replace imported wheat Potatoes are an economical crop for though they have a greater water content than wheat they yield half as much again in calories per acre Lately their iron and vitamin content has received plenty of attention It has been found that a pound of potatoes provides 330 calories and 100 international units of vitamin B_1 (in each case as much as 5 oz of bread) as well as 3 mg of iron If the potatoes are freshly lifted a pound also contains 135 mg of vitamin C Thus from a pound a day—and surely an Englishman can manage as much as that, seeing an Irishman eats 2 lb —a man will get 11% of his total caloric requirements, 25% of his iron 20% of his vitamin B_1 and (provided the potatoes are freshly lifted) about twice as much vitamin C as he needs , even taking an average sample the vitamin C content of a pound of potatoes is equivalent to 3 oz of orange juice The vitamin-B complex is particularly well represented in potato Thus in addition to B_1 a pound contains riboflavin up to 11% and nicotinic acid up to 36% of the day's needs as much B_6 and folic acid as a pound of national bread and as much pantothenic acid as a pint of milk The average composition of potatoes has lately been given by the Ministry of Health as follows

Water 78%, protein 1 2%, carbohydrate 16 2% Every 100 g is equivalent to 70 calories, and contains on an average calcium 8 mg , iron 0 7 mg , vitamin C, when freshly lifted 30 mg , before Christmas 12 mg , after Christmas 6 mg , vitamin B_1 40 IU , riboflavin 0 07 mg , nicotinic acid 1 4 mg The following are tentative values vitamin B_6 0 15 mg , pantothenic acid 0 3 mg and folic acid 0 12 mg

Those who wish to make the most of the vitamin-C content should therefore eat as many potatoes as they can between now and Christmas

CAPPING THE MILK BOTTLE

THE war has made it necessary to find a substitute for aluminium caps for milk bottles and Mr R Kerr, Ph D in the Tin Research Institute's publication No 113 describes his investigation into the effect on milk of a tin-zinc alloy (92% tin), tinned lead foil and tinned copper foil Undesirable contamination arose when milk bottles were capped with tinned lead foil, as the foil interacts into the cream layer, but satisfactory results were obtained with tinned copper and tin-zinc alloy foils The production of thin copper foil coated with tin is, however, uneconomic in war-time, and as the physical properties of the tin-zinc alloy were satisfactory, and it could be readily made with the standard equipment, a 100% substitution was effected It was used until the need for tin economy arose as a result of the war in the Far East

University of Oxford

In a congregation held on Oct 15 the following degrees were conferred

DM —*M W C Oldfield
BM —M G Ellis, W E Hunt, D S Goldfoot, *L J Bussell, *W H H Andrews, and *R E B Tagart

* In absence

University of Cambridge

Prof H Roy Dean, FRS, has been elected representative of the university on the General Medical Council for the next five years

Royal College of Surgeons of Edinburgh

At a meeting of the college held on Oct 21, with Mr J W Struthers, the president, in the chair, the following were admitted to the fellowship

W R Black, MB EDIN D G W Clyne, BM OXFD , P G L Essex Lopresti, MRCS T B FitzGerald, MB BIRM , R A Fleming, MB DURH , Leon Gillis, MB WITWATERSRAND , Edward Gledhill MD LEEDS , J E V Jones, MB CAMB , A N Reid, MB EDIN , E L Salingar MB LPOOL Max Sugar, MD VIENNA, LRCPE , and Harry Winter, MD TORONTO

Socialist Medical Association

On Saturday, Nov 7, Prof H Levy, D Sc, will address this society on 100 years of socialist theory On Nov 21, Mr W C W Nixon will speak on nutrition Both meetings will be held at the Conway Hall, Red Lion Square, London, WC1, at 2 30 PM

Medical Superintendents Society

A meeting of the main executive committee of this society will be held at the Station Hotel, Derby, on Saturday, Nov 7, at 11 AM

Biochemical Society

A meeting of this society will be held in the department of organic chemistry of the Imperial College of Science and Technology, South Kensington, London, on Saturday, Nov 7, at 11 AM

Royal Institution of Great Britain

Prof W V Mayneord, D Sc, will give a Friday evening discourse on Nov 6 at 5 PM He will speak on the measurement of radiation for medical purposes On Dec 18, at the same hour, Prof J W Munro, D Sc, will discuss the place of research in the control of injurious insects Both meetings will be held at the institute, 21, Albemarle Street, London, W1

Basic Principles of Hospital Admission

Addressing the Cambridge University Medical Society on Oct 21, the Minister of Health reviewed the large scale experiment in hospital organisation provided by the emergency scheme The main lessons of this experiment, said Mr Brown, are that the patient should go to the hospital best suited to his needs, not necessarily to that to which he may have subscribed through a contributory scheme, and not necessarily that with which his own doctor has some connexion, or that in which a bed is first found for him To this end the hospitals in an area of suitable size should work as a whole, and hospital finance must be so arranged that it will not hamper the patient's transfer to another hospital as his condition changes The areas must be of suitable size so that the patient shall not be taken unnecessarily far from his home, and both voluntary and municipal hospitals must serve the area in equal partnership

Royal Society of Medicine

There will be a general meeting of the fellows of this society on Tuesday, Nov 3, at 4 PM On Nov 4, at 2 30 PM, Mrs Lilian Lindsay, LDS, will read a paper to the section of history of medicine on medical polemics from Hunter to Owen, and on the same day, at the same hour, the section of surgery will hold a discussion on hernia which will be opened by Major General Max Page and Brigadier Harold Edwards On Nov 6, at 10 30 AM, at the section of otology, Mr W Stirk Adams, Mr James Crooks and Major R R S Strang will open a discussion on chronic middle ear suppuration in children At 2 15 PM on the same day Mr V E Negus will give his presidential address to the section of laryngology He will speak on the mechanism of swallowing, and afterwards Sir Arthur Hurst will open a discussion on neurological disorders of the mechanism At 2 30 PM on the same day Dr A W Matthew, president of the section of anæsthetics, will give his address to the section on progress in anæsthesia

Royal Society of Tropical Medicine and Hygiene

A meeting of this society will be held at 26, Portland Place, London, W 1, on Wednesday, Nov 4, at 4 PM, when Colonel N Hamilton Fairley, FRS, will read a paper by Colonel J S K Boyd and himself on bacillary dysentery and its modern treatment with special reference to sulphaguanidine

Manchester Medical Society

A meeting of this society will be held at 4 PM on Wednesday, Nov 4, at the medical school of the university, Manchester, when Sir Charles Wilson, PRCP, will deliver an address on morale in leadership All graduates and students of medicine are invited to attend

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Infectious Disease in England and Wales

WEEK ENDED OCT 17

Notifications —The following cases of infectious disease were notified during the week smallpox, 0 , scarlet fever, 2703 , whooping-cough, 907 , diphtheria, 971 , paratyphoid, 6 , typhoid, 6 , measles (excluding rubella), 5796 , pneumonia (primary or influenzal), 608 , puerperal pyrexia, 133 , cerebrospinal fever, 59 , polio myelitis, 24 , polio-encephalitis, 1 , encephalitis lethargica, 2 , typhus fever, 1 (at Bournemouth) , dysentery, 165 , ophthalmia neonatorum, 92 No case of cholera or plague was notified during the week

Deaths —In 126 great towns there were 1 (0) deaths from enteric fever , 3 (0) from scarlet fever, 2 (0) from measles, 5 (0) from whooping-cough, 15 (1) from diphtheria, 55 (7) from diarrhœa and enteritis under two years, and 17 (1) from influenza The figures in parentheses are those for London itself

Sheffield reported the fatal case of enteric fever Birmingham had 7 deaths from diarrhœa, Manchester 5

The number of stillbirths notified during the week was 202 (corresponding to a rate of 32 per thousand total births), including 18 in London

SMALLPOX IN FIFE

Up to Oct 23 notification of 28 cases of smallpox with 7 deaths had been received from the village of Methilhill or its near vicinity There is still no proof that the outbreak has any connexion with the Glasgow epidemic

Births, Marriages and Deaths

BIRTHS

ASHCROFT —On Oct 20, at Ripley Court, Surrey, the wife of Major D Walker Ashcroft, RAMC—a son
BEILBY —On Oct 19, in Edinburgh, the wife of Dr J H Beilby, of Bedale—a daughter
HORTON —On Sept 28, in Leeds, the wife of Surgeon Lieutenant Denys Horton, RNVR—a son
SANDON —On Oct 20, at Molesey, the wife of Dr Raoul Sandon —a son
SECKER WALKER —On Oct 19, at Farnborough, Hants, the wife of Dr G Secker Walker—a son
SYMMERS —On Oct 15 in Edinburgh the wife of Surgeon Lieutenant W St Clair Symmers, RNVR—a son

MARRIAGES

FRASER—HAGGIE —On Oct 22, at Dorchester Oxon, Thomas Alexander Fraser, MB, to Emily Elizabeth Haggie
LEE—PEARSON —On Oct 24, at Hampton Middlesex, Edward Lee, MB, to Joan Doris Pearson

DEATHS

HORNE —On Oct 21 at Warwick, Charles Eric Vernon Horne, MB EDIN , aged 44
MOYES —On Oct 23, at Warkworth, Robert Esmond Moyes, MD EDIN , aged 58
ROBERTS —On Oct 19 Arthur Roberts, TD FRCSL, late of Reading, and Bath, aged 81

Appointments

BATTY, C G, MD CAMB asst clin pathologist for Aberdeen
DFLORY G E , MSC LOND biochemist in the department of pathology of Preston Royal Infirmary
SCHAPIRA, DAVID MD VIENNA RMO at West Lane Isolation Hospital, Middlesbrough
SOMERSET V E , MRCS examining factory surgeon for Wem, Salop

SYNCOPE IN BLOOD DONORS

FAITH C POLES, M B LOND
CAPTAIN RAMC

MURIEL BOYCOTT, M B LOND
LATELY LIEUTENANT RAMC

(*Army Blood Transfusion Service*)

To an organisation which bleeds 100,000 voluntary blood donors a year, the prevention of faints is of considerable importance Of the first 10,000 donors bled by us only about 2 8% fainted, but even a small minority wastes the time and space at the disposal of the operator, and has a disproportionately large influence against recruiting Moreover, on two occasions a donor has injured himself by fainting after return to work, and such accidents must be avoided Our investigation was undertaken to discover, first whether any particular type of donor is likely to faint, and secondly whether prophylaxis is feasible

FAINTING REACTIONS

In the Army Blood Transfusion Service all donors are admitted into a waiting-room, and are asked for particulars of any recent illness or history of anæmia; nervous donors, who often produce large numbers of symptoms, are reassured by the medical officer All donors are kept waiting as short a time as possible, usually under 10 min The girl in charge of the waiting-room brings the donor into the operating-room, and leaves him lying on a couch in charge of the VAD The nurse explains the procedure to all new donors, while preparing the arm for the medical officer, who comes to each couch when the nurse is ready Local anæsthetic is injected, the needle is put into the vein and anchored with strapping The same nurse remains with, and talks to, the donor throughout, and donors can see and talk to each other At the end of the bleeding the nurse withdraws the needle, sees that the vein is adequately controlled by a gauze pad, and prepares her equipment for the next donor, before she allows the previous donor to sit up and walk to the rest-room Here he lies on a stretcher for 15 min, and has a cup of tea and a biscuit, he sits up for a further 5 min before his arm is dressed, and is then allowed to leave

The term "faint" has been applied to anyone who either loses consciousness, or who can obviously neither sit nor stand without doing so "Immediate faints" include those people who faint during or immediately after bleeding "Delayed faints" are those who faint when preparing to leave after their rest or on return to their work This paper takes no account of the small proportion of donors (perhaps 0 05%) who faint when only a negligible amount of blood has been removed, their reaction, which is certainly not due to loss of blood, is probably of emotional origin

In 116 faints encountered in bleeding a series of 4306 donors, the time of onset varied considerably, 6% fainted before 400 c cm of blood were removed, 57% after 400–440 c cm, and 4% during the rest period, 19% fainted when sitting up for the last 5 min rest and a further 14% were reported as fainting after return to work This last percentage is too low, since not all such faints are reported, particularly when the reaction is delayed several hours, but it is a most important group, both in causing accidents to donors and in discouraging others from volunteering

Some or all of the following clinical manifestations are shown by donors who faint Pallor is the most constant sign, being present in 9 people out of 10, the face is pale, the lips greyish, and in severe faints the hands also are affected Sweating is almost as common as pallor, it is not confined to the blush area but occurs all over the body The blood-pressure is low and may be unrecordable, the pulse-rate is slowed to 30–40 min or may be impalpable at the wrist Breathing is slow and shallow, although it may temporarily be rapid in association with the general restlessness at the beginning of the reaction Hyperventilation has never been observed before a faint About 1 person in every 4 loses consciousness; in some cases this may only be momentary, in others the period of unconsciousness may be longer and is sometimes accompanied by epileptiform convulsions, deviation of the head to one side, fixed dilated pupils and stertorous breathing The commonest prodromal symptoms are a generalised feeling of heat, nausea or epigastric discomfort Vomiting is not very common and when it occurs recovery is often rapid, in contrast, recovery is delayed by convulsions Incontinence of urine was noted in a few cases, and some people have also complained of severe cramp Facial pallor is not a reliable guide to the condition of the donor. It is usually, though not always, evident before the blood-pressure reaches its minimum, but sometimes the colour remains good for several seconds after the pulse has become impalpable at the wrist The return of normal colour does not necessarily run parallel with the recovery of the blood-pressure Most people are still pale when their blood-pressure has risen to a reasonable level, while a few regain their normal colour some time before their blood-pressure is high enough to permit their discharge Table I gives some indication of the time taken by the blood-pressure to return to normal, all readings were taken with the donor supine The systolic pressure may still be less than 100 mm Hg after an hour, and may take 2 hours to return to normal

TABLE I—TIME TAKEN FOR BLOOD PRESSURE TO RETURN TO NORMAL AFTER FAINTING

The systolic blood pressure may still be less than 100 mm Hg after 1 hour and may take 2 hours to return to normal

Age and sex	Blood pressure (mm Hg)							
	Before bleeding	Immed	Time after bleeding (min)					
			5	15	30	50	60	90
48M	125/	90/ (faint)			84/unr		94/68	
24M	172/98	138/72 (faint)	76/50	100/64	118/64		118/64	
24 F	115/			unr (faint)	83/66	88/66	96/67	96/74
19 F	108/	unr (faint)		88/60	90/66		95/66	108/66
30 F	124/	88/	unr (faint)	90/77	88/28	106/48		108/
56M	126/	(faint)	44/unr (faint)	94/62	98/58	122/72	120/70	

unr = unrecordable

POSSIBLE CONTRIBUTORY FACTORS

The factors most likely to predispose to syncope have been studied The numbers analysed are small but they may serve as a pointer to further investigations

Heat and humidity—No significant increase was observed in the summer months: from April to September, 5732 donors were bled and 166 fainted (2 9%); from October to March, 4991 were bled and 144 fainted (2 8%). On one occasion 54 donors were bled in a stuffy room in which the temperature rose to 110° F. and no-one fainted The humidity of the air in bleeding centres was estimated on many occasions and was also found to have no apparent relation to the number of faints Fainting has several times been observed in individual donors who were overheated by exertion

Sex and age—In a series of 4306 donors specially studied there were 1516 men and 2790 women Of the men 44 (2 9%) fainted and of the women 73 (2 7%). This difference between the sexes is not significant On the other hand there is a significant difference between the mean age of the fainters and non-fainters of both sexes

	Mean age in years		
	Fainters	Non fainters	SE of difference
Men	34 5	42 7	1 4
Women	32 9	46 6	1 6

The age-distribution in the two sexes is shown in fig 1 It will be seen that in some age-groups there is a big difference in the faint rate between the two sexes but the numbers of each group are too small for definite conclusions Greenbury (1942), however, in his analysis of the incidence of fainting in 5897 donors bled by the North-West London Blood Depot, found that women were more likely to faint than men, especially those in the 18–25 years age-group

Rate of taking blood—Variations in the rate of withdrawal from 2½ to 15 min had no apparent effect when the amount withdrawn was 540 c cm or less

Amount of blood taken—The effect of removing larger amounts of blood in a series of young factory workers is seen in the following comparison of donors bled consecutively during 2 months by the same medical officers

Amount removed	No of donors	Fainted
440 c cm	346	13 (3 8%)
540 c cm	410	35 (8 5%)

The youth of these factory workers is at least a contributory factor in this series Unfortunately it is rather a small group on which to base conclusions, but the difference is significant

Nervousness cannot always be a major cause of syncope in the group under discussion since many donors first faint at the second or third time they are bled Two medical officers fainted, one after giving the 6th and the other after giving the 15th pint of blood, at intervals of 3 months or more The faint-rate however is higher among donors bled for the first time

	No of donors	Fainted
First bleeding	4127	96 (2·3%)
Second or subsequent bleeding	3269	49 (1 5%)

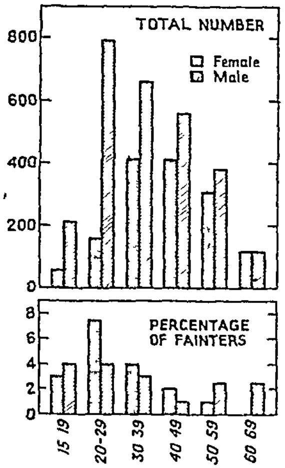

Fig 1 —Age and sex distribution of total donors and proportion of fainters in each group

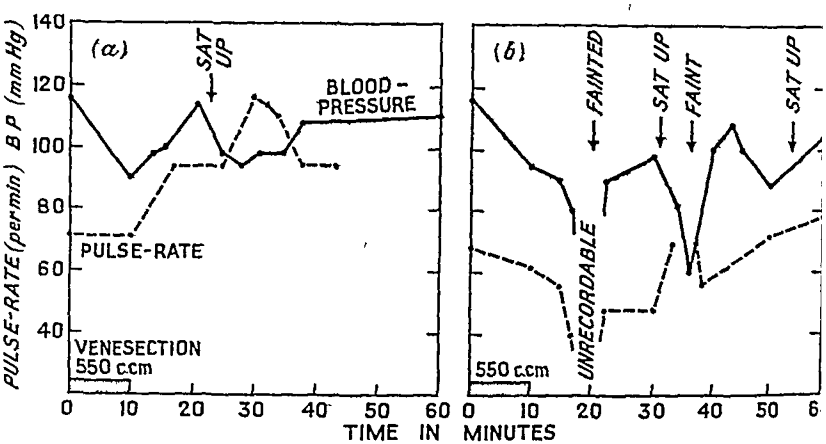

Fig 4 —Blood pressure and pulse-rate changes in the same subject after removal of 550 c cm of blood on t separate occasions (a) Skin-vessels normal, (b) skin vessels dilated by heat

Anæmia was apparently not a contributory factor Estimations done at the time of bleeding showed that the hæmoglobin in 145 non-fainting donors averaged 105% (80–132%) and in 35 fainting donors averaged 104% (71–135%) The hæmoglobin was estimated by the Sahli method and expressed on the Haldane scale Venous blood was used

Blood-volume —The surface area (SA) of the body, which is a rough guide to blood-volume, was found to be significantly lower for fainters than for non-fainters—i e, 2 0 and 2 6 times the SE of difference (Du Bois formula)

	Men		Women	
	No	Mean SA	No	Mean SA
Non-fainters	70	1 84 sq m	77	1 67 sq m
Fainters	38	1 78 „	68	1 61 „

Body form —Our observations suggest that fainting is evenly distributed among all types of body form and that there is no significant difference between the obesity factors for the men and women who fainted and for those who did not Of 147 non-fainters 58% were of the asthenic type, in comparison with 61% of 142 fainters

TABLE II—TIMES SINCE LAST MEAL IN 4436 DONORS AND 116 FAINTERS

—	Time (hours)										
	½	1	1½	2	2½	3	3½	4	4½	5	6
All donors	253	412	582	768	882	687	401	279	90	70	57
Fainters	4	7	14	15	25	18	14	3	2	7	7
Faints %	1 6	1 7	2 4	1 95	2 8	2 6	3 5	1 1	2 2	10 0	12 2
	Mean 2 3								Mean 7 4		

Fatigue seems important Air-raid wardens and others who have been unaffected on previous occasions have fainted when bled after a night on duty Fatigue may cause a depression of the normal blood-pressure, one person's pressure which was 102/68 mm Hg at lunch time was 80/48 mm Hg at the end of an arduous day work in summer

Time from last meal —If this is 4½ hours or longer t number of faints is significantly increased, from 2 3% 7 4% (table II) From ½ to 4 hours there is no significa variation in the distribution of the faints

Poor fluid reserves —It was thought that diminuti of the tissue fluid reserves from which the blood-volur is replaced might be important, particularly in donor who work in foundries and smith shops Of a group 656 such people 19 (2 9%) fainted, whereas 721 in a co trol group of the same sex and similar age-distributio had a faint-rate of 1 5% Further investigation of th problem was undertaken and will be discussed later

A normal low blood-pressure —The initial blood-pre sure is no guide to the likelihood of fainting In 5 unselected donors the mean initial systolic pressure w 128 mm Hg, while in 84 who afterwards fainted the mea initial reading was 126 mm Hg We thought it possib that those people with a habitually low systolic pressu would stand bleeding badly Armstrong (1939) says th a systolic pressure below 100 mm Hg is pathologica but our own findings agree with Rook and Dawson (193 who say that a low systolic pressure in a healthy subje often indicates a stable and adaptable cardiovascul system This is illustrated by the blood-pressure recor of four donors

Donor	Initial (lying)	After bleeding (lying)	After rest (lying)	Sitting
1	90/	80/	88/	
2	100/	92/	94/	
3	102/68	88/48	96/62	
4	100/56	102/56	84/40 & 95/50	95/5

EFFECT OF BLEEDING ON BLOOD-PRESSURE

The effect of bleeding on blood-pressure was studied a series of 707 donors, including 64 with immediate a 20 with delayed faints The blood-pressure was record before and immediately after bleeding, and in half t people again after 15 min rest The rules laid down the British-American Commission (1939) were observed nearly as possible, although it was impossible to ensu the constant relation to meals recommended, and on 100 cases were given the advised 10–15 min prelimina rest to allow the blood-pressure to reach a stable lev Readings in nearly every case were taken from the fr arm On occasions when both arms were used no co rections have been made, as the difference on the tw sides has been shown to be small (Shock et al 1940), an 200 observations gave the personal error of the observ as ±2 5% We noted that when a person is keyed up anticipation of bleeding the blood-pressure does not fa the anticipated amount even if he is rested until a stable level is reached (fig. 2).

	No of subjects	Mean fall in BP (%)	SD
Rest preparatory to bleeding	99	3.5	5.75
Rest, unassociated with bleeding . .	61	7.25	6.1

In 101 donors first resting until the blood-pressure reached a stable level and then submitting to the withdrawal of 440 c.cm. of blood without fainting, the mean fall in blood-pressure noted immediately after bleeding was 7% (SD 11.2). The total change in blood-pressure is approximately the same whether the donor is given a planned preliminary rest of 10–20 min. before he is bled or whether he is bled in the routine way which usually entails lying down for 10 min. on the operation couch.

	Subjects	Mean fall in BP (%)	SD
Planned rest and bleeding	101	9.1	11.5
Routine rest and bleeding	606	10.3	12.85

Those donors who faint ½–6 hr. after they are bled have not shown an unusual fall in blood-pressure immediately after bleeding (fig. 3). In 20 such cases the mean fall was 8.5% (SD 6.23).

A low blood-pressure after bleeding was common to all the immediate faints and the 61 cases recorded showed a mean percentage fall of 30.5 with standard deviation of 11.3 (fig. 3). In 60 people the blood-pressure was followed during the actual removal of the blood. In most cases the fall was steady throughout; in some it became steeper after the 400 c.cm. mark had been reached and this fall was accentuated when the amount withdrawn was increased to 500 c.cm. or more. One donor however showed a fall in blood-pressure from 118/68 to 100/64 mm. Hg when 440 c.cm. was withdrawn, and this fall was increased by only 2.5%—from 118/80 to 97/70 mm. Hg—when on another occasion 1000 c.cm. was withdrawn. On both occasions the pulse-rate remained constant. A series of 21 people showed a mean fall of 7.4%, 8.7% and 13.0% after 300, 350 and 440 c.cm. of blood had been withdrawn.

In 377 donors a third reading of blood-pressure was taken; the systolic pressure in half the cases had returned to normal or was rising at the end of 15 min. rest, while in the other half it was still falling. Of 16 delayed faints reported to us 15 had shown a falling pressure after 15 min. rest. Three examples illustrate this; the blood-pressure (mm. Hg) was taken with the subjects lying down.

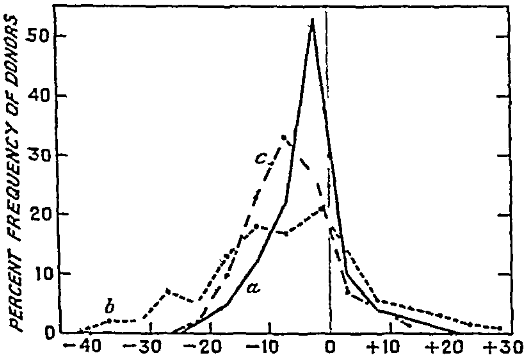

Fig. 2.—Changes in systolic blood pressure produced by 15 min. rest (a) as a preliminary to bleeding, (b) plus bleeding, and (c) unassociated with bleeding.

Before bleeding	After bleeding	After rest	Faint
135	132	104	On return to work
150	140	110	Later in street
118	102	100	On leaving

EFFECT OF BLEEDING ON PULSE-RATE

In 107 donors an attempt was made to correlate changes in pulse-rate and blood-pressure during the planned preliminary rest and during bleeding. In 53 cases the pulse-rate remained unaltered (within a range of ± 5), and in these people the blood-pressure fell slightly (mean drop 7.1%). In 21 cases the pulse-rate rose more than 5 beats per min. when the blood-pressure remained virtually unaltered (mean fall of 2.0%). The greatest fall in blood-pressure (mean fall of 14%) was accompanied by a decrease in pulse-rate of more than 10 beats per min. (27 cases), and all cases of syncope immediately after the giving of blood showed this bradycardia. This slowing of the pulse was noted by Ebert and Stead (1941) in volunteers from whom large amounts (700–1200 c.cm.) of blood were withdrawn. We have been unable to discover whether the pulse-rate alters or the blood-pressure falls first. Cardiac slowing and a fall in blood-pressure appear to start simultaneously and run a parallel course, as in the following case, a patient aged 19:

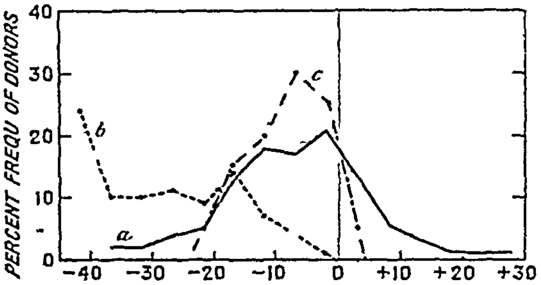

Fig. 3.—Differences in systolic blood pressure readings taken just before and 2 min. after removal of 440 c.cm. blood. (a) Donors who did not faint, (b) donors who fainted immediately after bleeding, and (c) donors who fainted on return to work.

	Before bleeding	After bleeding	After 2 min	 5 min	 10 min
BP (mm. Hg)	118/72	52/30	68/40	78/40	92/54
PR per min.	100	43	54	56	62

In a very few cases the blood-pressure fell before there was any change in pulse-rate. Slowing of the pulse is not such a constant finding in delayed faints. If the heart can prevent the drop in blood-pressure, which in this type of faint seems to be the primary change, by increasing its rate the donor may feel shaky without actually fainting (fig. 4), as the experience of the following patients shows:

Woman aged 20—

	Before bleeding	After bleeding	After rest	Sitting up		
BP (mm. Hg)	124/58	92/50	100/62	96/66	92/66	96/68
PR (per min.)	70/	70/	94/..	94/	116/	94/ Felt shaky, no faint

Same 6 months later—

BP	116/68	80/46	Unrec., fainted	104/60	90/60
PR	68/	57/	40/	64/	64/..

Man aged 19—

BP	118/72	52/30 fainted	108/58	88/58	50/? Felt faint
PR	100/.	40/	68/	80/ .	80/

This compensatory rise in pulse-rate is seen in fig. 4a.

EFFECT OF POSTURE ON BLOOD-PRESSURE

Although we realised that the efficiency of the cardiovascular system cannot be judged by the behaviour of the blood-pressure only (Schneider and Truesdell 1922) we thought it possible that delayed syncope occurred in those people in whom the systolic blood-pressure normally falls when they change from the recumbent to the erect position. In one girl, for example, the blood-pressure when recumbent was 120/76 mm. Hg and dropped to 110/70 when sitting up. She was bled and fainted on return to work. A follow-up of our delayed faints, however, showed that fainting was not confined to those normally showing an orthostatic fall in pressure; for a subject whose systolic blood-pressure normally rose on standing up might not always exhibit this rise after giving blood. In these people an orthostatic fall seems to be a temporary legacy of blood loss; for example, one woman showed a rise in blood-pressure on sitting up from 156/98 to 166/98 mm Hg in spite of which she fainted on return to work the first and second times she was bled , on the third occasion her blood-pressure (which was 156/86 before bleeding and 140/74 after bleeding) fell from 128/84 in the recumbent position to 122/84 and 116/70 when erect She was rested until her cardiovascular system (judged from the behaviour of the blood-pressure) was reacting normally to changes in posture, and she felt no ill effects from this bleeding

Ellis and Haynes (1936) draw a distinction between true orthostatic hypotension and poor adaptation to changes in posture In the former the fall in both systolic and diastolic pressure is immediate while in the latter a rise in diastolic accompanies a gradual fall in systolic pressure, the diastolic finally falling also Our cases of delayed syncope resemble in the main this latter type. The fall in systolic pressure is gradual, reaching a maximum in 5–10 min after sitting up (table III) and giving rise to symptoms when still measuring 80–90 mm Hg Fainting is as a rule accompanied by sweating and pallor but this is by no means invariable and several cases have been reported to us who maintained a good normal colour the whole time, in this way resembling cases of true orthostatic hypotension

TABLE III—ORTHOSTATIC FALL IN BLOOD-PRESSURE AFTER BLEEDING

The orthostatic fall in blood pressure is maximal after 5–10 min in the vertical position, and this fall can be produced in someone with a normal response when there is vasodilatation of the skin

Age and sex	Blood-pressure (mm Hg)								
	Before bleeding (lying)	Immediately after bleeding (lying)	After rest (lying)	Time after sitting up (min)					
				2	3	5	6–10	15	30
25 F	108/	74/	96/		82/		78/		
32 M	114/	100/	110/				92/ (felt faint)	96/	
56 F		44/	122/68				108/		120/74
30 F		72/	100/			90/	114/		
32 F	135/	120/	126/			112/	110/	116/	
25 M	132/	118/	120/	128/	120/		120/		132/
19 M	118/60	52/30	108/28	108/	88/58	50/?	(faint)		
Donor AB (normal)									
30 F	118/	88/	100/				108/		110/
Donor AB (skin vessels dilated)									
	124/60	92/50	114/62		94/66	92/66	96/66		

In most donors who felt faint on sitting up the diastolic pressure was found to be unaltered or slightly lower after the change in position, and after a few minutes it fell parallel with the systolic pressure, as in the following four cases

	Subject—A	B	C	D
Lying down	108/58	100/50	140/86	120/70
Sitting up	88/58	90/50	128/82	136/70–104/52

Those who did not feel faint on sitting up usually showed the small rise in diastolic pressure normally expected on assuming the erect position, as follows

	Subject—A	B	C	D
Lying down	98/50	100/60	108/70	104/70
Sitting up	108/68	132/64–128/70	120/78	110/72

We thought it possible that if the normal reflex constriction of the small skin vessels was completely or partially prevented by the application of heat (in these experiments the subjects were given a comfortably hot bath) the peripheral resistance would be reduced enough to cause an orthostatic fall in both systolic and diastolic pressures It was found however that heat alone in most cases is not sufficient to do this

	Subject—A	B	C
Lying down	128/62	112/70	104/68
Sitting up	135/62–130/72	114/70–108/70	100/72–100/68

If blood loss is also suffered there is a postural fall in systolic and diastolic pressures, and syncope may result presumably owing to a lowered peripheral resistance

	Subject—A	B	C
Lying down	126/82	102/62	94/60
Sitting up	112/78–110/78	70/42	78/54

FAINTING AND SHOCK

The most complex type of faint is that which occurs some hours after the donor is bled In these cases syncope is not the result of any one factor, but, as McDowall (1941) pointed out, the cumulative effect of many The cardiovascular system may compensate successfully for the initial reduction in blood-volume , but if then the effective circulating volume is further reduced by pooling of the blood in the small vessels of the skin or splanchnic area, this compensating mechanism is no longer adequate and circulatory failure results In many ways these faints resemble the vasovagal attacks described by Lewis (1932) but there is a longer time between the stimulus and the attack, and recovery is slower Similar cases were described by Ferris, Capps and Weiss (1935), who consider that a stimulus may produce primarily a fall in blood-pressure , cardiac slowing , or cerebral vasomotor changes In most of the immediate faints the changes in blood-pressure and cardiac rate happened so rapidly that it was impossible to say which came first In cases of delayed faints, on the other hand, the blood-pressure often fell while the pulse-rate remained normal Formerly it was thought that any great blood loss produced a rapid pulse-rate Recently Grant (1941), in his survey of air-raid casualties, has stressed the point that a low blood-pressure with a slow pulse may be found in cases of severe wounds and grave hæmorrhage Some of our most severe cases of syncope had a blood-pressure of under a 100 mm Hg after an hour's rest, accompanied by a thready pulse of normal rate All eventually recovered with warmth, fluids and raising the foot of the couch

PROPHYLACTIC MEASURES

The following procedure was tried in an endeavour to reduce the number of both immediate and delayed faints

Administration of normal saline—As Bazett (1941) has shown that there may be up to 18% reduction in the blood volume of a dehydrated man it was decided to try the effect of a litre of normal saline given 2–4 hours before bleeding to men from hot shops such as foundries and smith shops The faint-rate, which is high for such men (most of them are over 40), was reduced in a highly suggestive manner On these numbers, however, the difference does not quite reach the level of significance when exact methods of fitting are employed

	Donors	Faints
With saline	487	4 (0 8%)
Without saline	654	19 (2 9%)

A rate of 2 9 is high for men with a mean age of 43 5

In spite of the reduction in the number of faints the mean fall in blood-pressure for the series receiving saline was not significantly different from the control series These results agree with those of Van Liere and his colleagues (1940) who found that administration of fluids by mouth immediately after blood loss was of no assistance in restoring blood-pressure Bock and Robertson (1919), however, by forcing up to 5 litres of fluid, succeeded in raising the blood-pressure in wound shock, a method impracticable to us Two investigations were undertaken to find out whether the decrease in the faint rate was due to a more rapid and complete restoration of blood-volume

The level of the hæmoglobin in ten men who work 6 hours a day in a shed containing furnaces at 1200° F was observed at intervals for 4 days after bleeding In one man full dilution had taken place at the end of an hour, in one at the end of 2 hours, in three at the end of 5 hours, in three at the end of 24 hours, while in the remaining two men dilution had started in 1 hour and 5 hours but was not complete at the end of 48 or 96 hours These rates of dilution are comparable with those found by Whitby (personal communication) and

Wallace and Sharpey-Schafer (1941) in normally hydrated men

The rate of dilution of the hæmoglobin was followed in four normally hydrated people and in the same people bled (at a later date) 2–4 hours after they had drunk a litre of normal saline Only one man diluted quicker after saline On the first occasion dilution was not complete at the end of 24 hours while after saline full dilution had taken place in ¼ hour, this was followed by partial concentration with complete dilution again in 5 hours Similar results were obtained by Ebert, Stead and Gibson (1941) in two of three cases who received a litre of normal saline intravenously after removal of 18–20% of the blood-volume, the third showed a more rapid and lasting dilution

It seems probable, therefore, that the decrease in faint-rate is not due to a rapid replacement of the blood-volume

Prophylactic glucose —As there is a significant increase in the number of faints if the time from the donor's last meal is over 4 hours it seemed possible that a low blood-sugar might be a contributory factor Blood-sugar estimations have been done on twelve fainters and twelve controls of the same age and with the same interval after a similar meal In all cases the blood-sugar was within normal limits, the mean value for the fainters was slightly lower than for the controls Glucose, 50 g, has been given prophylactically before bleeding to 800 people Alternate donors arriving at the centres received glucose, the others were given a saccharine drink. The faint-rate for those who had had glucose was not reduced

Procedure adopted —In the last 2772 donors bled by one of us the following procedure has been adopted Donors were not rejected because of a previous history of fainting, associated or unassociated with bleeding, provided it is not accompanied by any organic disease They were referred if it was considered that they were excessively fatigued, and were fed with tea and biscuits before as well as after the blood was taken if their last meal had been taken more than 4 hours previously Only 440 c cm of blood was withdrawn and if the donor was under 7 st in weight this was reduced to 350 or 400 c cm Donors from hot workshops were given a litre of normal saline before they were bled Whenever possible a series of blood-pressure readings were taken on all donors who had fainted on return to work after a previous blood-letting If the systolic pressure fell as a result of bleeding or during the rest period and continued to fall on sitting up the donor was given further rest, even if feeling perfectly fit at that time

CONCLUSIONS

Fainting after the removal of blood affects both sexes and different builds of people equally, but is more common in the young The incidence is raised by increasing the amount of blood withdrawn from 440 to 540 c cm, but not by increasing the speed of withdrawal, by bleeding tired and hungry people, but not by bleeding in a moderately hot and humid atmosphere Fatigue is difficult to assess, and now, when many men and women in industry are working longer hours than they have ever done before, it is difficult to decide who is and who is not fit to give blood It seems, however, that a man who is used to night work can be bled when he comes off his shift without any ill effects, while to bleed an air-raid warden after an unaccustomed night up will often cause fainting Seltsovsky (1940) also considered that hunger and fatigue were the two most important causes of fainting in blood donors

Loss of 440 c cm of blood leaves 97% of blood donors apparently unaffected, and if any fall of blood-pressure occurs it is small This fall cannot be reduced by rest before bleeding, since emotional tension prevents the systolic pressure from assuming its usual stable level The donors who show the biggest drop in blood-pressure show also slowing of the pulse-rate In those who faint at the end of bleeding the onset of symptoms is almost always associated with a fall in blood-pressure and pulse-rate An orthostatic fall in blood-pressure may be a temporary phenomenon due to blood loss It is maximal 5–10 min after the donor gets up and accounts for one group of delayed faints

The most dangerous type of faint is that which occurs ½–6 hours after bleeding when the donor is back at his work or out in the street Prevention of such faints is of great importance A number of these donors have been found to have a transient orthostatic hypotension after being bled, and when this can be detected the subsequent faint can probably be prevented by giving the donor additional rest

Glucose, 40 g, given prophylactically to donors was without effect on the faint-rate, but for men from hot workshops the rate was suggestively (though on the numbers observed not quite significantly) reduced by giving them a litre of normal saline some hours before bleeding By following the procedure described the general faint-rate has been reduced to 1 75% (a fall of more than a third in the last 2772 donors bled)

We wish to thank members of the Army Blood Transfusion Service who have helped us to collect facts and given advice, and Dr J A Fraser Roberts for help with the statistical analyses

MIGRATION OF FOREIGN BODIES

LAMBERT ROGERS, FRCS, FACS
SURGEON CAPTAIN RNVR, PROFESSOR OF SURGERY IN THE UNIVERSITY OF WALES, SURGICAL CONSULTANT TO THE RN AND EMS

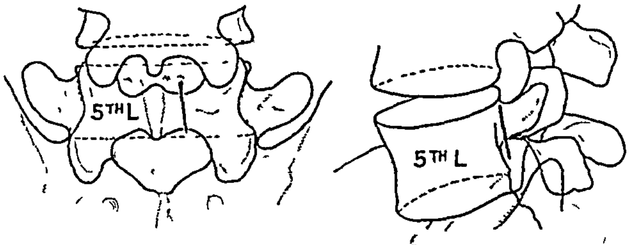
THIS curious case of delayed symptoms from a needle in the theca of a soldier who was unaware of its presence raises again the question whether migration of foreign bodies such as pins and needles does take place as is popularly believed

A gunner, aged 21, who had been four years in the Army, reported sick because of pain in the lower part of his back and legs He was given some palliative treatment and returned to duty, but as he continued to complain of persistence of the pain, X-ray films were obtained of the lower part of the spine To everyone's astonishment, including that of the patient himself, these revealed the eye-end of part of a sewing needle lying inside the spinal canal, behind the body of the fifth lumbar vertebra (see figure) Inquiry elicited the fact that when he was 4 years old he had rolled on the floor and a sewing needle had entered his back and broken off Two attempts to remove the embedded part, made at the time at his local hospital, had failed Inquiry at the hospital showed that these took place on Aug 23, 1926, but unfortunately the X ray films had not been kept and the hospital record merely stated "FB present" His chief symptom now was pain in the lower part of the back and thighs, induced particularly when sitting and flexing the head Occasionally the pain seemed "to shoot through the spine" and in the two months before he was admitted to hospital he had lost 2 st in weight The only objective findings were exalted sensation over the lower lumbar and sacral dermatomes and diminished motor power in the glutei, the right being estimated at 60%, the left 80% The knee- and ankle-jerks were exaggerated

Operation —On Feb 16 with the patient under nitrous oxide, oxygen and ether, laminectomy (L4 and L5) was performed, the dura opened and the cauda equina exposed The piece of needle was seen lying among the elements of the cauda to the right of the midline and covered by a thin film of arachnoid It was encrusted with rust and old blood-clot, and easily removed The patient made a good recovery and was discharged to duty symptom-free

Were the symptoms in this case the result of migration and recent change in the position of the needle, or of a mild inflammatory reaction consequent upon some slow chemical changes ? The deposit of rust and old blood-clot and the localised arachnoiditis suggest the latter explanation There is a widely held belief, however, even among members of our profession, that foreign bodies such as pins and needles may travel considerable distances in the tissues, and this is worthy of examination Gould and Pyle (1897) state that the wanderings of pins and needles in the body are well known and relate that on Nov 15, 1802, the celebrated Lettsom spoke of an old lady who sat on a needle while riding in a hackney coach ; the needle passed from the injured leg to the other one, where it was extracted Since drawing attention to this question earlier this year (Rogers 1942), the following cases have come to my notice

A woman, aged 70, while eating suddenly felt a sharp prick in her throat and thought she had swallowed a needle She was rushed to hospital, but laryngoscopy failed to reveal it Sixteen days after the accident a foreign body was palpated beneath the skin over the anterior border of the sternomastoid and under local analgesia a piece of moderately stiff, bent wire 2 9 cm in length was removed There was no associated cellulitis or infection (Duhan 1940, Graham 1941)



Anteroposterior and lateral views of eye end of piece of sewing needle in spinal canal

Three months after introducing a piece of slippery elm into her vagina a woman aged 31 was readmitted to hospital with a brawny mass about the size of a cricket ball in the left upper quadrant of the epigastrium From this about 10 oz of pus were evacuated along with the piece of wood 4 in long She made a good recovery (Ross and McLellan 1942)

A needle localised by X rays on the plantar surface of the foot was found at operation on the following day to be visible under the skin between the big and second toes of the foot (Dr W H Gregory's case)

A hypodermic needle broke off when an injection was being given about 2 in above the elbow A small incision was immediately made at the site but the fragment could not be found Two hours later an X ray film showed the fragment lying over the deltoid It had moved approximately 10 in in 2 hours time (Dr J M Walker's case)

The eye end of a darning needle entered between the sole and the upper of the shoe of a doctor's wife aged 40, and broke off, a piece of the needle penetrating the sole of the foot, 4 weeks later she felt pain in the inner side of the thigh of the same leg and later the same day removed a small piece of needle which she was able to pick out herself (Mr John Patrick's case)

A girl aged 16 was brought to hospital by her mother because "a needle was sticking out of her tummy" Examination showed the blackened end of a needle projecting just above and to the left of the umbilicus It was firmly embedded in the abdominal wall and local infiltration with novocain and much pulling were necessary before it could be extracted The mother stated that her daughter had swallowed the needle when a child of 2½ (Dr J D R Murray's case)

Other cases related to me are too vague to be here included Some instances of unexplained foreign bodies found after death are reported an unexplained needle in lung (Rusby 1942), a darning needle surrounded by dense fibrous tissue in the centre of the right lobe of the liver, discovered at autopsy (Dr J M Walker), a needle 3½ cm long discovered in the saphenous vein of an old woman in the dissecting-room and so covered with rust and eroded that it broke into pieces on being withdrawn from the vein, to the wall of which it was adherent (Mr S K Wright of Manchester)

DISCUSSION

The travelling of projectiles or fragments of such which have penetrated vessels and become emboli can be readily understood and has been amply discussed by Sir John Bland-Sutton (1919) An example of this type which has recently come to my notice may be quoted A radium needle which had been implanted in a mass of glands in the left posterior triangle of the neck was successfully removed from the right branch of the pulmonary artery by Mr Harold Upcott of Hull The needle had evidently traversed the left innominate vein, superior vena cava, right auricle and ventricle The reported migration of pins and needles, independently of the blood-stream, however, is not as easy to understand There can be no doubt that many such foreign bodies remain at their site of lodgment for long periods, Dr James Brailsford tells me he has seen cases in which needle fragments have been retained at one site for 20 years or more and, like myself, he is sceptical about many reported cases of migration The few which are noted here, however, seem sufficiently definite to accept as evidence that such migration can occur occasionally It is permissible to conclude that foreign bodies such as pins and needles may remain fixed at their site of lodgment, rarely travel as emboli in blood-vessels, and rarely travel either through the subcutaneous tissues or along fascial or intermuscular planes, for varying distances Migration in general seems to be towards the trunk (i e, in a proximal or centripetal direction) and towards the surface As Sir John Bland Sutton remarked, "Missiles often attain more curious places by accident than they could obtain by design"

I am indebted to these friends and colleagues who have kindly written to me about the cases to which reference has here been made

THE state of the capillary walls is of wide interest in connexion with the hæmorrhagic diseases and certain vitamin deficiencies In particular the work of Wolbach and Howe (1926) and more recently of Hunt (1941) has emphasised the importance of changes in and around the smaller blood-vessels in scurvy and the prescorbutic state, and there is evidence that significant alterations in the properties of capillary walls occur as the result of deficiency of vitamin P in man (Armentano et al 1936, Scarborough 1939) and in the guineapig (Bacharach et al 1942a and b)

The wall of a capillary will rupture if sufficient force is applied to it, in the case of a skin capillary the small hæmorrhage or petechia can be observed with the naked eye Stress can be applied to skin capillaries by two methods and the capillary fragility (or resistance) measured in two ways Procedures employing the "positive-pressure principle" make use of the fact that, during venous occlusion intracapillary pressure rises in tissues distal to the point of occlusion, this rise may be sufficient to rupture skin capillaries, and the capillary resistance may then be assessed in terms of the number of petechiæ counted in a given area after the circulation has been restored In methods based on the "negative-pressure principle" the capillaries are ruptured by means of suction applied to their walls through the skin, and the capillary resistance is usually measured in terms of the suction (mm Hg negative pressure) required to produce one or more petechiæ in the area under examination

It has usually been assumed that the methods based on these two principles give directly comparable results since they measure the same function—the resistance of the capillary walls to stress There are, however, reasons for doubting this *assumption* With negative-pressure methods, for example, the amount of suction acting on the capillary walls might be expected to depend to some extent on the thickness and elasticity of the skin, and in practice this is found to be the case Further, since the end-point in negative-pressure methods is the appearance of a single petechia or at most three or four, it may be objected that only the very weakest vessels are being investigated and this in only a very restricted area Results with the positive-pressure methods may be considered more representative of the capillary population as a whole, since a much greater number of capillaries are subjected to stress and the area over which petechiæ are counted can be larger There is still another important difference in the two methods, for with positive pressure the circulation through the capillaries is interfered with for periods up to 15 minutes, whereas the negative pressure is permitted to act for only 30–60 seconds Positive-pressure methods thus involve some degree of capillary anoxæmia, and furthermore the pressure to which the capillary walls are subjected is unknown and is not necessarily the same in all areas below the occluding band Lastly, there is no evidence that quantitative assessment of the fragility of the surface capillaries gives any indication as to the capillary fragility in the deeper tissues, nor has it ever been shown that capillary fragility is related to capillary permeability

Bell, Lazarus and Munro (1940), employing a positive-pressure method developed originally by Gothlin (1931), in an investigation on 310 apparently healthy medical students, were unable to show any effect of vitamin-P preparations in increasing capillary resistance Scarborough (1939, 1940), using chiefly a negative-pressure method described by him (1941), has obtained evidence in persons suffering from spontaneous, conditioned and induced vitamin deficiency states that vitamin-P preparations can increase capillary resistance which falls, or is found to be low, as the result of the lack of this material in the food The discrepancy between these observations may be due to the different types of clinical material used, but before making this assumption we thought it wise to make a direct comparison between the two methods on the same subjects

Two other groups of workers have compared the capillary fragility or resistance as determined by various positive- and negative-pressure methods In 130 children Brock and Malcus (1934) found a rough correlation between the results obtained by two methods but the findings were not treated statistically O'Hara and Hauck (1936) compared the two methods in 4 adults who were tested repeatedly over 10–14 weeks, Gothlin's method was used for the positive-pressure and the method of Dalldorf and Russell (1935) for the negative-pressure readings No correlation was found between the results obtained by the two methods

METHODS AND CLINICAL MATERIAL

The positive-pressure method of Gothlin (1931) was used exactly as described by Bell, Lazarus and Munro (1940) Petechial counts were made in a 6 cm circle in the antecubital fossa without the aid of a magnifier by two independent observers on both arms held about two feet from a 300 watt lamp The mean of the four observations was used for the statistical calculations The negative-pressure method was that described by Scarborough (1941) in which suction is applied for half a minute The capillary resistance was determined in three standard areas on the forearm, usually the right Area 1 and area 3 lay just below the antecubital fossa, while area 5 was at the wrist The results from each area have been used separately in the calculations which follow

Both methods were applied at the same session to 142 apparently healthy second-year medical students between the ages of 18 and 23 The capillary resistance was first determined by the negative-pressure method and immediately afterwards by the positive-pressure method

RESULTS

The results of the investigation are set out in table I In some individuals a very high negative pressure (500 mm Hg) produced no petechiæ, in others the critical pressure was accidentally over-shot so that several petechiæ were produced These results were discarded and accordingly the groups in table I always contain less than 142 The mean values are interesting since they were obtained with healthy young people and may be taken as standards of reference for the two methods There is a statistically significant but low degree of correlation between the results of the two methods in areas 1 (lateral side of the proximal forearm) and 3 (medial side of proximal forearm), the correlation in area 5 (distal forearm) is not significant With correlations of the low order obtained (0 29) it is not possible, with any degree of accuracy, to predict a negative-pressure reading from a given positive-pressure reading or vice versa If the data are treated as a grouped series according to the positive-pressure readings (or alternatively the negative-pressure readings) as in table II, the low correlation becomes more apparent

TABLE I—CORRELATION BETWEEN POSITIVE AND NEGATIVE-PRESSURE METHODS OF DETERMINING CAPILLARY RESISTANCE

—	No of cases	Mean	Standard deviation	r	Standard error (of r)	Significance
Pos pres (no of petechiæ)	113	4 0	3 5	− 0 22	0 094	+
Neg pres, area 1 (mm Hg)		283 8	63 8			
Pos pres (no of petechiæ)	103	4 1	3 7	− 0 29	0 099	+
Neg pres, area 3 (mm Hg)		340 1	78 1			
Pos pres (no of petechiæ)	92	4 3	3 8	− 0 15	0 105	−
Neg pres area 5 (mm Hg)		454 1	71 9			

Each of the tests is consistent within itself Scarborough, in some unpublished work, has shown that there is a correlation of + 0 80 to + 0 89 between the negative-pressure readings in similar areas on the right and left arms In the series reported here the correlation between readings in areas 1 and 3 is + 0 89 and between those of areas 3 and 5 + 0 77 Bell, Lazarus and Munro (1940) showed that the correlation between the findings on two arms tested simultaneously by Gothlin's method was + 0 66 and that between the findings in the antecubital fossa and an area further down the forearm was + 0 92

TABLE II—RESULTS CONSIDERED IN THE FORM OF A GROUPED SERIES

Positive pressure Readings			*Negative pressure Readings*		
Pos pressure (no of petechiæ)	Neg pressure (mm Hg) Mean of corresponding readings		Neg pressure, areas 1 & 3 (mm Hg suction)	Pos pressure (no of petechiæ) Mean of corresponding readings	
	Area 1	Area 3		Area 1	Area 3
0–1 75	279 4	367 2	Up to 200	4 75	3 33
2–3 75	302 7	345 2	225–300	3 91	4 66
4–7 75	278 3	342 6	325–400	2 95	3 57
8 and over	246 4	333 6	Over 400	1 20	2 93

CONCLUSIONS

It is evident from the low correlation that the results obtained in this group of 142 apparently healthy medical students by a positive- and negative-pressure method are not comparable The problem as to which of the two methods is to be preferred is not brought nearer solution by this work, nor does it throw any light on the relative importance of vitamins C and P in increasing the resistance of capillary walls There seems to be a belief that the solution of the latter problem lies along chemical lines Chemical procedures, however, give little information beyond that concerning input and output, and are as a rule unable to decide how and how much a subject is affected by his altered or deficient diet Such considerations will continue to apply even if—in addition to those already available for ascorbic acid—effective chemical methods are devised for determining the concentration of vitamin P in organic fluids Some physiological method of detecting deviation from the normal is essential, with the present available knowledge tests of capillary fragility seem, in our opinion, to offer the best approach

SUMMARY

The capillary strength was tested in 142 healthy students by negative- and positive-pressure methods

The results obtained by the two methods gave a correlation which, though significant, was low

The tests were consistent within themselves, but, because of the low correlation between them, the results given by the two methods are not comparable

Certain expenses of this work were defrayed by a grant from the Rankin Medical Research Fund of the University of Glasgow

VITAMIN-C NUTRITION

IN THE ROYAL NAVY AND IN A SECTION OF THE CIVILIAN POPULATION DURING WAR-TIME*

GERALDINE Z L McNEE
M SC LOND

JAMES REID
M B GLASG, M R C P

(*Gardiner Institute of Medicine, University of Glasgow*)

THE occurrence of sore and bleeding gums in naval ratings and trawler crews engaged on naval duty attracted official notice in 1940, chiefly because these men were being clinically labelled scurvy, or subclinical scurvy, without adequate investigation At the time the question of a diminution in vitamin C in war-time diets was being much discussed, and the authorities resolved to investigate the state of vitamin-C nutrition in the Royal Navy The investigation was carried out chiefly by assessing the tissue reserves of ascorbic acid, using the saturation test of Harris and Abbasy (1937) but other methods are also discussed It was clearly desirable to contrast the results in naval ratings with those of the civilian population, and a group of men of similar age and social status fully engaged in war-work in a large motor-engineering works provided this control We were also fortunate in being able to collect 9 cases of fully developed scurvy in the wards of the Western Infirmary, Glasgow, during the time the naval investigation was in progress Observations on these patients amplified and checked our work on the naval ratings and healthy civilians It is not considered that the 9 examples of genuine scurvy in adults, seen within a period of 1½ years, represent any increase due to war conditions They were collected to aid our work, and would ordinarily have been treated in a number of different hospitals

DETAILS OF OBSERVATIONS

In the two groups, 392 ratings, comprising representatives of the crews of destroyers, corvettes, trawler mine-sweepers, depôt ships and submarines, and 176 male civilians were examined in the spring and autumn of 1941

General Dietetic Inquiry—Careful inquiry into the dietetic habits of the two groups was made, and each man appeared to be taking an average well-balanced diet in which the vitamin C was derived chiefly from potatoes and vegetables Attempts to calculate the vitamin C content of individual diets for comparison with the results of the saturation test were soon abandoned, since, as Ungley (in another part of this investigation) and others have shown, it is impossible without complete control of the man and accurate weighing and testing of the diet to know the actual vitamin-C content of the food as cooked and eaten

Clinical Observations—All the naval ratings and civilians appeared to be in good health Particular attention was paid to the state of the mouth and gums in 118 naval ratings, among whom we were fortunate in being able to include men of different nationalities There were 72 British, 12 Canadian, 16 Royal Indian Navy, 12 French, and 6 Polish ratings In 6 men (5 British and 1 Pole) swollen and painful gums which bled easily on pressure were detected at an examination in late autumn The teeth of the British and French ratings were moderately satisfactory, but dental attention was required in a number of them. In the Canadians and Poles dental fillings were numerous, but the teeth were in good condition The teeth and gums of the men of the Royal Indian Navy may fairly be described as perfect

Saturation Test—The method of Harris and Abbasy (1937) was applied to all the 392 naval ratings and 141 civilian engineers, which involved a series of over 1000 individual tests in the spring and autumn of 1941

The test dose chosen was 700 mg of pure ascorbic acid, dissolved in water This was taken by mouth, and urine was collected from the end of the third to the end of the sixth hour (standard three hour period) The volume of urine excreted in the standard time was measured and 9 c cm of urine was immediately added to 1 c cm of glacial acetic acid in a test-tube The ascorbic acid content of the sample was estimated by titration with the dye 2,6-dichlorophenolindophenol The test dose was repeated daily until " saturation " was indicated by a sharp rise in the urinary excretion of ascorbic acid, and the amount of ascorbic acid required was taken to be inversely proportional to the original tissue reserves of vitamin C The results of the tests were interpreted as follows

Urinary output of ascorbic acid in standard three hour period (mg)	Degree of saturation of tissues
More than 50	Complete saturation
20–50	Almost complete , full saturation with next dose
5–20	Saturation approaching , complete in one or two doses
Less than 5	Incomplete saturation , no measure of tissue reserves possible

The complete results are shown in table I, which has been condensed to save space It is shown that a progressive increase in the percentage of men saturated occurs after each successive test dose and that less ascorbic acid is required (about 700 mg) for saturation in the autumn than in the spring Three test doses (2 1 g) and four test doses (2 8 g) were required to saturate the majority (60–70%) of naval ratings and civilians respectively in the autumn, as compared with five test doses (3 5 g) for both groups in the spring In both the naval ratings and civilian engineers there was a wide variation in the number of test doses required for saturation, but on the average the sailors required one test dose (700 mg) less than the civilians in the autumn, while in the spring there was no significant difference between the two groups None of the men observed any improvement in their physical condition after saturation and no relation could be established between the number of test doses required for saturation and age, body-weight, type of work or time at sea No difference was observed between representatives of the crews of depôt ships, destroyers, corvettes and submarines A sufficient number of complete results was not obtained with the crews of trawler mine-sweepers who did not take kindly to the delay required for testing on reaching port On the evidence available, however, they were a little below the naval ratings

The lower reserves of ascorbic acid observed in the spring in both groups is considered to be due mainly to the progressive deterioration in the ascorbic acid content of potatoes occurring throughout the winter and spring (Olliver 1940)

Of the 6 sailors found to have sore and bleeding gums in November, 1941, 1 was saturated and 2 almost

* This is one part of an investigation undertaken in 1940 at the request of Surgeon Vice Admiral Sir Percival Nicholls, Medical Director-General of the Navy and aided by a special financial grant from the Board of Admiralty The work was carried out by observers in three areas of Scotland in which local circumstances provided different lines of approach to the same problem—the occurrence of sore and bleeding gums in men of the Royal Navy and auxiliary vessels In one area a comparison of the state of vitamin-C nutrition in sailors and civilians was undertaken, and is reported here In a second area, observations and experiments in men with sore and bleeding gums were made under controlled conditions in the wards of a Naval hospital and diets were carefully checked in men actually serving in small ships In a third area the frequent presence in port of many small vessels of the trawler minesweeper class made possible extensive dietetic surveys It is expected that the other parts of the investigation will be published in due course

* N = naval ratings, C = civilian engineers

saturated after one test dose of ascorbic acid The remaining 3 required three test doses before saturation was attained The ratings of the Royal Indian Navy whose teeth and gums were perfect required more ascorbic acid for saturation since none of them was saturated after three test doses Oral hygiene among these men was excellent They used their own method of cleaning teeth and gums by first chewing the end of a twig and then using the chewed end as a tooth and gum brush

Capillary Resistance Test —This test has been claimed to be of value in the diagnosis of vitamin-C deficiency by Öhnell (1928), Göthlin (1933), Stocking (1933), Daldorf (1933), Bell, Lazarus and Munro (1940), but has been condemned as unsatisfactory by Greene (1934), Abt, Farmer and Epstein (1936) In the present investigation the capillary resistance test has been compared with the saturation test in a series of 59 healthy adults The tests were all carried out in the laboratory and not " in the field," so that only 24 naval ratings are included The remaining 35 comprised doctors, medical students, laboratory technicians, hospital workmen and porters

TABLE II—CAPILLARY RESISTANCE TEST

Method	No of men	No of petechiæ			
		Antecubital fossa		Wrist	
		Range	Mean	Range	Mean
Positive pressure	Saturated, 9	0– 9	3 0	0–3	0 3
	Unsaturated, 29	0–14	2 9	0–3	0 4
Negative-pressure	Saturated, 17	0–100	26	0–2	0 4
	Unsaturated, 42	0–100	22	0–5	0 8

Two methods of carrying out the test have been employed—the positive- and negative pressure methods In the positive pressure method a sphygmomanometer cuff, placed round the arm above the elbow, is maintained at a pressure of 80 mm Hg for 5 minutes and then released In the negative pressure method a suction chamber is applied to a standard area of skin for one minute, the suction exerted being 100 mm Hg below atmospheric pressure The standard areas selected were (*a*) the centre of the antecubital fossa, and (*b*) one inch above the anterior aspect of the wrist A circle, one inch in diameter, was stamped on the skin at these sites, and after the test the number of petechiæ within the circle were counted with the aid of a lens in good light The two methods—positive and negative pressure—were generally carried out simultaneously on the right and left arm of each individual

From the results shown in table II the range and mean number of petechiæ were, for all practical purposes, similar in saturated and unsaturated alike Consequently no relation could be established between the capillary resistance test, assessed by the positive- and negative-pressure methods, and the tissue reserves of ascorbic acid estimated by the saturation test

Nine Patients Suffering from Scurvy —In these patients the only constant clinical manifestations of the scorbutic state were perifollicular hæmorrhages and extensive purpuric hæmorrhage in the lower limbs Perifollicular hyperkeratosis of the skin, especially of the legs, often referred to in scurvy, was present in the majority; but we are not convinced that this is an essential feature of scurvy. The possibility of its relation to persistent uncleanly habits cannot in our opinion be ruled out, and all 9 patients had been very neglectful in their personal hygiene We also wish to emphasise strongly that spongy and bleeding gums are not essential for a diagnosis of scurvy, and they did not occur in our edentulous patients All 9 patients had taken grossly defective diets, potatoes and vegetables being practically absent for a minimum period of four months before the onset of symptoms The capillary resistance test (positive-pressure method) was abnormal in only one out of 5 cases examined All 9 patients were rapidly cured by administration of ascorbic acid

DISCUSSION

It is generally agreed that potatoes and vegetables are the basic sources of vitamin C in this country In peace-time this was supplemented in some sections of the community by the regular consumption of citrous fruits In war-time this has been impossible, and a deterioration in the response to the saturation test in these groups has been observed by Francis and Wormall (1942) The whole population is thus now reduced to a more uniform and level state of vitamin-C nutrition, derived from the two main basic sources The occurrence of scurvy in healthy adults is unknown when potatoes and vegetables are eaten daily, and so long as the supplies of these foods are adequately maintained and consumed in sailors and civilians, scurvy cannot occur in epidemic form In the present investigation a state of vitamin-C nutrition far short of saturation was found to be compatible with good health, and no improvement in physical well-being was observed after saturation There is good evidence that vitamin C plays an important part in the healing of wounds, and that in such circumstances high tissue-reserves of ascorbic acid are beneficial (Lund and Crandon 1941) We suggest, and hope later to provide supporting evidence, that vitamin C may be chiefly concerned with reparative processes in the body and that scurvy appears only when the tissue reserves have become so depleted as to be unable to cope with ordinary wear and tear

Our results seem to show that in adults, both in the Royal Navy and among civilian workers, the levels of vitamin-C nutrition are adequate for good health, and we conclude that the causation of sore and bleeding gums in ratings of the Royal Navy is not vitamin-C deficiency.

SUMMARY

The majority of 392 Royal Naval ratings and 176 civilian engineers, whose main sources of vitamin C were potatoes and vegetables, required respectively three and four test doses of 700 mg ascorbic acid for saturation in autumn, as compared with five test doses for each in spring

Six naval ratings showed sore and bleeding gums out of 118 tested, but we were unable to associate this with vitamin-C deficiency The ratings of the Royal Indian Navy had lower tissue-reserves of vitamin C, yet their teeth and gums were perfect It is considered that good oral hygiene was of major importance in maintaining the healthy state of their teeth and gums

The capillary resistance test was found to be of no value in assessing the state of vitamin-C nutrition No relation could be established between the number of petechiæ induced and the results of the saturation test Moreover the test was positive only in one of 5 patients with fully developed scurvy

We conclude that in healthy adults, relying almost entirely on potatoes and vegetables for vitamin C, a state far short of saturation is the rule, and that provided the present standard of diet is maintained no outbreak of scurvy is likely to appear

It is suggested that, in adults at least (we are not considering growing children), vitamin C is mainly concerned with tissue repair, and that in health and ordinary circumstances of service and work the maintenance requirements of this vitamin are small but have not yet been accurately determined

We wish to thank Temporary Surgeon Rear-Admiral J W McNee, consulting physician to the Royal Navy, who controlled the different parts of the investigation, for advice and criticism We are indebted to officers and men of the Royal Navy and to Albion Motors Ltd for their cooperation, and to the physicians of the Western Infirmary, Glasgow, for access to patients suffering from scurvy.

EPILEPSY*

ANTHONY FEILING, MD CAMB, FRCP
PHYSICIAN TO ST GEORGE'S HOSPITAL AND THE MAIDA VALE HOSPITAL FOR NERVOUS DISEASES

A LARGE number of electroencephalographic studies have been made on epileptic patients for some years past This method of studying the brain arises from the work of Berger (Jena) who in 1929 published record of changes of electrical potential in the human brain Later Adrian and Matthews and Grey Walter in this country confirmed his observations, Adrian demonstrating that the alterations in electrical potential arose in the normal subject from an area in the occipital lobes connected with vision The recording of very small electrical changes is now possible In most people, with electrodes applied to the intact scalp, the only part of the brain from which recognisable waves can be elicited is the occipitoparietal visual association area and then only as a rule when the eyes are closed

The Electroencephalogram

This normal rhythm of electrical discharge is called the alpha rhythm and has a frequency of about 10 waves per second, the frequency being remarkably constant for the individual In many organic pathological lesions of the brain the rhythm and form of the waves are materially altered, so-called delta waves appear, with a frequency of less than about 7 per sec, and these often have a larger amplitude than the normal alpha waves By recording waves simultaneously from several places the focus of origin of the abnormal waves can often be discovered and a lesion thereby localised

In epilepsy two distinct EEG abnormalities must be noted first, in many patients, an abnormal rhythm may be constantly present between attacks (a resting or interparoxysmal abnormal rhythm), secondly, in all patients during convulsion or other type of epileptic seizure, there is in addition another form of abnormal rhythm characteristic of the particular type of seizure taking place A resting or interparoxysmal abnormal rhythm is found in a large proportion of epileptic subjects, but unfortunately from the point of view of diagnosis not in all those who are on clinical grounds undoubted cases of genuine epilepsy The proportion has been variously estimated Golla and Grey Walter place it at about 50%, Williams at about 60% Earlier American estimations placed the proportion much higher, thus Jasper and Kershman reported abnormalities in over 95%, while Lennox Gibbs and Gibbs found that only about 8% of their patients with overt seizures had normal EEGs Such discrepancies are in part accounted for by differences in standards taken as normal This is a new method and time is required before all workers reach agreement on a norm The resting or continuous abnormality consists of a delta type of wave, larger and proceeding at a slower rate than the normal alpha rhythm In cases of major epilepsy or grand mal it has been shown that these abnormal discharges arise most often from a focus in the middle part of the superior and middle frontal convolutions In petit mal the focus is often postcentral, while in pyknolepsy in children it appears to be in the occipital poles

In many patients, especially those whose attacks are mostly minor, the amplitude of these resting delta waves can be much increased by overbreathing; in some cases after hyperventilation of the lungs apparently normal waves may take on abnormal forms A lowered blood sugar has also been shown to increase the size of abnormal rhythms (Golla and Walter) The age of the patient seems to affect the incidence of this resting abnormality Golla and Walter state that few patients over the age of 40 will be found to exhibit it, but a high proportion of patients below the age of 20 do so An increase in the size of these delta waves in a known epileptic subject indicates that an attack will develop in the near future, in fact attacks have been accurately foretold, even in the absence of any subjective warning or premonition on the part of the patient The abnormal EEG records obtained during actual epileptic seizures vary, particular varieties being characteristic of grand mal, petit mal and psychical attacks In grand mal the waves are much increased in frequency, from the normal of about 10 per sec up to 25 or 30, are generally of larger size than normal and often show a spike, in petit mal there is a peculiar mixed rhythm, consisting of some slow waves with a rounded or flattened top and of other spiky-topped waves moving at a faster rate, psychical attacks are characterised by a smooth and slow discharge Thus in major epilepsy the cortical discharges seem to be abnormally rapid and in psychical attacks abnormally slow, while in petit mal there is an alternating fast and slow discharge Putnam and Merritt have been able to correlate the bouts of periodic dullness in some epileptic patients with the presence of an abnormal rhythm consisting of slow square-topped waves similar to those found as part of the picture in petit mal attacks

Bromides and phenobarbitone given intravenously while records are being taken produce a decrease in the rate of the cortical discharges, hence on this evidence they should be in theory as valuable in the treatment of major epilepsy as they are in practice The same drugs slow still further the rate of discharge in psychical attacks, while in petit mal their effect is uncertain, here again the experimental findings agree with clinical experience On the other hand, the resting abnormality found in about 50% of epileptic patients is but little affected by sedative drugs Golla and Walter, however, state that it is sometimes abolished by disodium diphenylhydantoinate, which in these cases also controls the attacks What contribution can be made by the EEG towards the diagnosis in a doubtful case of supposed epilepsy? First, a normal record in a patient during a period of freedom from an attack does not exclude the diagnosis of epilepsy Secondly, an abnormal EEG, either in the resting phase or obtained by overbreathing in a patient liable to recurrent attacks of uncertain nature, in whom no definite signs of an organic lesion of the brain are forthcoming, affords strong presumptive evidence that the attacks are epileptic, even if no account of them can be provided by an eyewitness Thirdly, the nature—whether epileptic or hysterical—of a fit or attacks may be determined by a record taken during the actual attack

Williams has reported on the EEG records in cases of acute head injuries and in the chronic states following them In the immediate post-traumatic period the epileptic type of dysrhythmia is seen but seems to have no prognostic significance in regard to the development of epilepsy later, and only indicates the presence of cerebral tissue which is abnormal as a result of the injury In cases where traumatic epilepsy did develop, the pattern of the EEG was similar in all respects to that obtained in idiopathic grand mal epilepsy, and it does not seem possible to predict, by EEG studies made during recovery from the injury, the development later of traumatic epilepsy Grey Walter states that the type of EEG peculiar to ordinary petit mal is not produced by injuries.

---

* Extracts from three Lettsomian lectures delivered at the Medical Society of London in July, 1942 The lecturer dealt also with fits associated with other organic disorders, and with clinical varieties of the idiopathic disease, its periodicity, postconvulsive phenomena diagnosis and treatment. The lectures will be published in full in the *Transactions* of the Medical Society

In view of the recognised hereditary factor in epilepsy investigations were indicated of the apparently healthy relatives of epileptic patients, and on healthy people in none of whose relatives epilepsy was known to exist. Critchley and Williams noted some time ago that in two pairs of identical twins the EEGs were pathognomonic of epilepsy, though in each pair only one member had epilepsy. Lowenbach investigated 37 relations (none of whom had ever shown clinical epilepsy) of 11 epileptic patients and found that 17 had abnormal EEGs. Lennox, Gibbs and Gibbs took records of 183 persons closely related to 94 epileptic subjects, of these only 2.2% had shown epileptic seizures. Of the 183, 60% had abnormal EEGs, or as these writers term it cerebral dysrhythmias. Compared with these a control group of 100 persons chosen from families believed to be free from epilepsy showed abnormal records in only 10%. Lennox and his colleagues also investigated both parents of 55 epileptic patients and in 35 instances found the records of both parents to be abnormal, while in as many as 95% the EEG of one parent was abnormal, in only 5% were the records of both parents normal. These workers also found dysrhythmias similar to those in the parents of epileptic patients in children with behaviour disorders and in many schizophrenic patients. Thus in addition to people who show both clinical epilepsy and resting cerebral dysrhythmias, a much larger group display the EEG abnormality only. In the series studied by Lennox and his colleagues, the cases of abnormal EEG without clinical evidence of epilepsy outnumbered the overt cases of epilepsy by 20 to 1.

More work is required before this cerebral dysrhythmia can be accepted as specific to epilepsy, but enough has been discovered to suggest that such dysrhythmia indicates a genetic fit-disposing character (Golla and Walter). Thus the existence of a hereditary or constitutional factor in epilepsy receives strong support from all these investigations. This work seems to afford some help in the always difficult task of advising on the questions of marriage and parenthood in epileptic patients. It is clear that if an epileptic patient marries he should select a spouse with a normal EEG, the offspring of such a union are much less likely to have epilepsy than the offspring of parents who both show cerebral dysrhythmias, even although neither has had clinical epilepsy. From their studies in America Lennox and his colleagues estimate that people with epileptic predisposition, as evidenced by cerebral dysrhythmia, constitute about 10% of the community. We might therefore look forward to a normal EEG being required as an essential condition before marriage, just as a negative WR is already so required in some communities.

Critchley asks what factors will convert an epileptic predisposition into clinical epilepsy. This question is bound up with that of the symptomatic epilepsy seen in cerebral disease, and with traumatic epilepsy. The answer can only be suggested in cases where there is pre-existing knowledge of the EEG of the patient. Again, if the EEG proves to be abnormal in a healthy person, is prophylactic treatment with any of the usual sedative drugs likely to be of value? On this point our present knowledge is not yet sufficient to justify a definite answer.

Visceral Variants

Abnormal visceral sensations are a well-recognised form of aura in many cases of major epilepsy. One of the commonest auræ is a peculiar almost indescribable epigastric sensation; other common varieties are a choking feeling, like suffocation, a tightness in the chest, palpitations, sometimes nausea. Such abnormal sensations may sometimes constitute the sole content of an attack, but in others the morbid sensations may be followed by objective manifestations affecting chiefly the heart, the vasomotor system and sometimes the respiratory system. The most striking example of this epileptic variant—for I unhesitatingly place it in that category—is the condition described by Gowers (1907) under the name of the vasovagal attack. Unfortunately the term vasovagal syncope has been more recently applied by Lewis to what have been called for years "fainting fits," and some slight confusion in nomenclature has been caused. I must make it quite clear that the following remarks apply to the type of attack described by Gowers and later by Ryle.

Both writers refer to the type of case earlier described by Nothnagel as angina vaso-motoria. The condition is in my own experience decidedly rare and it is surprising that Ryle has encountered as many as 93 cases. Attacks affect both sexes, but unlike ordinary epilepsy seem to be unusual below the age of about 25, most patients are over the age of 30. I have yet to encounter a case in childhood, or adolescence, although epilepsy in other forms is so common in those periods of life. It is very probable, as Ryle suggests, that many of these attacks have in the past been erroneously regarded as heart attacks, and on their first appearance possibly even as examples of coronary thrombosis. The patient has any or all of the following symptoms: a peculiar and severe sense of prostration, shows immobility, extreme subjective and objective coldness, the limbs exhibiting a marble-like chill, a sense of constriction in the chest with difficulty in breathing, sometimes pain, seldom very severe and often better described as a discomfort substernally and sometimes in the arms as well, resembling in distribution the pain of a true angina pectoris, pallor of the face; change in the pulse, which generally becomes slow (as low as 50 or 40) but which occasionally definitely accelerates, shallow and rapid respirations, occasionally mild tetany, almost certainly due to the hyperventilation. To this picture must be added what Ryle considers one of the striking symptoms, an anguor animi—the sensation of impending death, terrifying to the patient and so intense in many patients that it persists in every succeeding attack, although experience has denied the reality of the threat. Passage of a large amount of dilute urine often follows an attack.

It is not surprising that the first, at any rate, of such attacks should be regarded by a medical observer as a serious heart attack or be thus classified by a doctor consulted later by the patient. The more benign nature of the condition can as a rule only be established by its repetition without other ill effects. Although the periodic incidence of these attacks without evidence of any organic disease might in itself suggest an epileptic foundation, there is other evidence to support this connexion, which also tends to confirm the hypothesis that this vasovagal syndrome is due to a "low level" epileptic discharge arising in medullary centres.

Gowers observed the combination of vasovagal attacks and epilepsy in 2 patients, and its connexion with migraine in other cases. Ryle refers to a case in which a vasovagal attack was always followed later in the same day by a true epileptic seizure. He also quotes Symonds who observed 2 patients with attacks of the vasovagal type, including the anguor animi, of whom one presented signs of a tumour of the medulla oblongata and the other was a case of neurosyphilis in which autopsy disclosed miliary gummata of the medulla.

Kinnier Wilson proposed the term periventricular epilepsy for a type of disorder localised chiefly in neurosympathetic ganglia round the ventricles, mainly the third and fourth. He pointed out that though such attacks, including the vasovagal type, last as a rule longer than those of ordinary epilepsy, they may be quite brief, and that the onset, usually slower than that of most cases of epilepsy, may at times be quite sudden. That this type of attack—vasovagal or medullary epilepsy—may be associated with other and more common types is exemplified by a case now under my observation.

A big strong man now aged 33 suffered from the age of 14 from occasional attacks of what appear from the description to have been typical petit mal. In the last year however his attacks have become more frequent and of a different kind. These are slow in their development, he wakes in the morning feeling depressed and low, after some hours—usually about midday or in the early afternoon—the attack comes on with an uncomfortable sense of constriction in the chest, sometimes amounting to real pain, and a feeling of suffocation. He feels chilly and his hands become cold. He has time to lie down before he loses consciousness for a very short period, in which however he is seen sometimes to become stiff for a moment, there are never any convulsive movements. On recovering consciousness he has a headache, and is collapsed with icy cold hands and feet and a feeling of complete prostration He also has amnesia for all that has happened from the onset of the attack A doctor called in to see him after two of these attacks felt sure that he must have had a severe heart attack, for his pulse was almost imperceptible and the extremities icy cold In spite of this his general health is excellent and a recent complete physical examination supported by X-ray examinations of the skull and heart, a cardiogram, examinations of the blood and cerebro spinal fluid, and a blood sugar estimation have all failed to reveal any organic basis for the attacks The frequency of the attacks has been lessened by full doses of phenobarbitone

Traumatic Epilepsy

Besides being important in war-time, traumatic epilepsy is common in civilian practice, chiefly as a result of motor accidents

AFTER GUNSHOT INJURY

Figures of the incidence of epilepsy following gunshot wounds of the head are available from the last war, in 1920 the records of the Ministry of Pensions showed that out of 18,000 cases of such wounds 4 5% had developed epilepsy. In France Behague found epilepsy in 12 1% of 3523 cases These figures, however, do not distinguish between the incidence of epilepsy in wounds with, and wounds without, perforation of the dura mater Other statistics of the incidence of epilepsy after gunshot wounds of the head giving information on this point are those of Rawling, Steinthal and Nagel, and Credner and Wagstaffe All these observers are agreed in finding a greater incidence of epilepsy with wounds penetrating the dura mater

Thus Rawling reported in a series of 452 cases of gunshot wounds of the head of all types an incidence of epilepsy in 25%, and in 228 cases with penetration of the dura an incidence of epilepsy in 32 8% Steinthal and Nagel found an incidence of 28 9% in a total of 639 cases, and an incidence of 31 6% in 348 cases with penetration of the dura Credner gives an incidence of 38 2% in a total of 1990 cases, and of 49 5% in 1234 cases with dural penetration Wagstaffe's figures were an incidence of 9 8% in a total of 377 cases, and an incidence of 18 7%—nearly double—in 176 cases with dural penetration

Ascroft has recently published his findings in 317 patients receiving pensions for gunshot wounds of the head, the series excludes those who died as a result of their head injuries within 4 years, and those who received blunt injuries of the head and wounds of the cerebellum The series therefore comprises only the more severe types and contains a large proportion with wounds penetrating the dura mater He summarises his findings as follows

Of the 317 cases 107 (34%,) developed epilepsy Up to the end of the year 1940, 14 (4 4%) of the patients had died One and probably 2 others died of complications of the brain wound, the remaining 11 of intercurrent conditions In cases in which the dura had been penetrated fits were twice as frequent (45%) as in the scalp and skull wounds in which the dura was intact (23%) Scalp wounds due to missiles are more likely to be followed by epilepsy than are scalp wounds due to blunt injury There was no evidence that removal of metallic foreign bodies from the brain diminished the liability to epilepsy Prolonged wound sepsis, as indicated by delayed healing, favours the subsequent onset of epilepsy, both in cases in which the dura has been penetrated and in those in which the integrity of the dura has been preserved Epilepsy is more common after wounds affecting the sensoro motor cortex than after wounds of the polar region of the cerebral hemisphere The presence or absence of concussion (as judged by immediate unconsciousness) after gunshot wound does not influence the subsequent liability to epilepsy The first fit may occur within a few hours after injury, or may be delayed at least as long as 20 years Epilepsy begins more often in the first 2 weeks and thereafter the liability to epilepsy progressively diminishes In 30 of the 96 cases in which the course of the epilepsy is known fits ceased some years before the patient was last examined This subsidence of epilepsy occurred most often in cases in which fits began in the first fortnight after injury, less frequently when fits began within the first 2 years and never when the first fit occurred more than 2 years after the injury

Ascroft's investigation confirms the general opinion that epilepsy is more likely to develop after wounds penetrating the dura, but it is noteworthy that epilepsy developed in as many as 23% of cases in which the dura was not penetrated The types of epileptic attack included major convulsions without any obvious focal onset, attacks with a definitely focal onset in 31% of the cases and attacks of petit mal Accurate information about the date of onset of the epilepsy in relation to the date of wounding is given for only 84 of his cases In 56 of these epilepsy appeared within the first year, and in 19 of the 56 in the first month, of the remaining 28 patients, 10 developed fits in the second year, 4 in the third year, 4 in the fourth, 1 in the fifth, 6 between the sixth and tenth years, 1 between the eleventh and fifteenth years and 2 between the sixteenth and twentieth years after the original injury The site of the injury to the brain appears to have less influence upon the development of epilepsy than might have been expected, for though it is more common after wounds of the sensori motor cortex it may follow injury of any part of the brain, excluding the cerebellum, which rarely gives rise to epilepsy Ascroft's findings may be compared with those in 343 craniocerebral injuries, reviewed by Wolf, in German soldiers surgically treated in the war of 1914–18 In 1941 traumatic epilepsy was found to be present in about 23 3 of these patients, 120 of whom had had perforating bone wounds

IN CIVILIANS

The incidence of epilepsy after injuries in civilian life presents a brighter picture, chiefly no doubt because most of these are closed and not penetrating wounds, but again statistics vary considerably

Thus Brun in 221 cases of civilian head injuries found an incidence of epilepsy in 8% Schou found 4 5% in 200 cases, while Feinberg in an analysis of 47,130 cases of head injuries reported to an insurance company between the years 1919 and 1933 discovered only 50 cases of traumatic epilepsy (about 8 cases in 1000) Rowbotham's recently published figures on the incidence of traumatic epilepsy after "blunt" head injuries in peace time reflect, I think, the nearest approach to present day normal figures in these cases Of a series of 430, 11 developed epilepsy (2 5%) In every case the injury had been received not less than 5 years before the inquiry was made The incidence of traumatic epilepsy is definitely less after civilian injuries than after the injuries of war, and if fits (probably due to extradural, subdural or subarachnoid hæmorrhage) developing within a few days of closed civilian injuries be excluded, the incidence of traumatic epilepsy becomes still lower The type of epilepsy developing after closed injuries of civil life is most often the major generalised convulsion

Thus Symonds found that of 28 cases, 24 exhibited generalised attacks, the attacks were at first of the minor type in 11 cases and became of a major type later I too have noted this tendency to progress from a minor to the generalised major convulsion in several cases In Rowbotham's cases 2 out of 11 patients showed attacks of the petit mal type only Fits with a strictly focal onset and a typical spread of the Jacksonian type are not common after closed injuries, but when seen they may be brought about by a contrecoup lesion A man recently under my care sustained a fracture of the skull in the right frontal region with a temporary *left* hemiplegia, 5 years later he developed typical attacks of Jacksonian epilepsy beginning always in the right hand Occasionally the attacks became generalised with loss of consciousness Since the attacks were not controlled with sedatives operation was carried out and the left motor cortex explored A cystic condition with cortical atrophy was discovered, clearly the result of an old severe contrecoup injury at the time of the original injury to the right side of the skull

Nevertheless, traumatic epilepsy may follow closed injuries of civilian life whether there has been a fracture of the skull, or not In 3906 cases of fractured skull collected by Feinberg, epilepsy developed in 19 (about 0 5%), in 16,762 cases without fracture of the skull he found epilepsy in 24 cases (about 0 125%) It thus seems that the chances of the development of traumatic epilepsy are increased by skull fracture The time of onset of epilepsy after the injury—the latent interval—appears to be much the same with the closed as with the penetrating injuries, if we exclude the uncommon cases in which fits begin a few days after the injury In most cases fits appear during the first year, after about 18 months the liability seems to diminish rapidly

It is not easy to decide exactly what factor or factors really determine the origin of the epilepsy With fits appearing within a week or so of the injury hæmorrhage of some kind, whether extradural subdural or subarachnoid, must be the chief factor in closed injuries In penetrating injuries hæmorrhage may of course again play a part but the factor of infection has also been taken into consideration In late epilepsy a direct injury to the surface of the brain producing cicatricial changes with a neuroglial scar is the type of lesion most often found Why, then, should only a small proportion of cases develop epilepsy ? The answer to this question may be found in some constitutional factor—possibly a hereditary cerebral dysrhythmia

In cases where epileptic fits develop within a few days or weeks of injury, medicinal treatment should always be employed, whether surgical treatment is to be instituted or not The indications for operation in these early cases must be based on all the clinical features, for epileptic attacks alone are seldom sufficient reason for surgical exploration unless they are persistent and their nature points to a focal origin, such as local bleeding or suppuration or localised compression of the cerebral cortex In epilepsy developing later—which is commoner—the same general rule holds good medical treatment should be tried first and should be practised on exactly the same lines as already laid down for idiopathic epilepsy Many—and I am one—consider that all cases of severe head injury should be given a course of prophylactic treatment by sedatives even if no symptoms of epilepsy have appeared Unfortunately the EEG does not help us to decide which cases ought to receive prophylactic treatment, because cases of head injury with a definite cerebral lesion often show an abnormal EEG, which cannot be distinguished from that found in patients with ordinary epilepsy of the grand mal type , but if a patient shows such an abnormal EEG long after clinical evidence of an injury has disappeared, there is all the more reason to go on with prophylactic sedative treatment In most cases the lesions responsible for late epilepsy is a neuroglial scar which must be localised and completely removed with as little new surgical trauma as possible , only those cases are likely to benefit from operation in which the site of such a scar can be located, either from the nature of the fits or from the EEG or from ventriculography If a successful operation seems possible it should not be delayed too long, since if fits are repeated over a long period it becomes more difficult to get rid of them Dott considers that even with carefully selected cases operation is unlikely to benefit more than about half

EHRLICH'S DIAZO REACTION AND SULPHAPYRIDINE

JOSEPH MORROW KENNEDY, M B BELF, D P H
MEDICAL SUPERINTENDENT OF LODGE MOOR HOSPITAL, SHEFFIELD, LECTURER ON INFECTIOUS DISEASES AT SHEFFIELD UNIVERSITY

I CAN find no reference in any of the English journals to the presence of a positive Ehrlich's diazo reaction in the urine of patients receiving sulphapyridine , but since the introduction of sulphapyridine treatment we have found the test useless for diagnosis and prognosis of infectious diseases Observations made on 50 consecutive patients at Lodge Moor Hospital suffering from various diseases and all treated with sulphapyridine showed a positive reaction in every case, even where only a small dose of the drug was administered

The reaction depends on the fact that if sulphanilic acid is acted on by nitrous acid diazosulphobenzol is formed, which unites with certain aromatic compounds present in the urine to form aniline colours What these compounds are remains unknown. The reaction with sulphapyridine apparently cannot be due to the sulphapyridine itself or to its acetylated form, for sulphapyridine is an σ-substituted pyridine derivative, and only β-substituted derivatives would be expected to give a diazo reaction It is more probably caused by some derivative of the drug, or of a substance produced in the body during the detoxification of such a derivative The reaction is invariably obtained in the urine even after small doses

When given to patients, neither sulphanilamide nor sulphaguanidine gave a positive reaction , and the reaction was also negative when sulphapyridine was dissolved directly in the urine The diazo test, though it has lost its original value, has become useful for deciding whether the patient has been given sulphapyridine before admission to hospital

The solutions used were saturated solution of sulphanilic acid in 5% hydrochloric acid , 0 5% solution of sodium nitrite , and strong liquid ammonia If, on the addition of these, the urine became dark red and the froth crimson the reaction was held to be positive , if the urine became just red and the froth was unchanged the reaction was held to be doubtful , no colour change, of course, meant a negative reaction

The reaction is usually positive within 12–18 hours of administration of the drug, but may vary within fairly wide limits which do not seem to be associated with the size of the dose , thus in one case in the series of 50 it was positive within 9 hours, when the patient had received 2 g , in another it was positive in 12 hours after 0 75 g , and in a third it only became positive after 3 days when a total of 8 g had been given The reaction remains positive while the patient is under treatment with sulphapyridine, and persists for 2 or 3 days afterwards In one case—the only one in which the drug was given intravenously instead of by mouth—it persisted for 5 days

Ehrlich's aldehyde reaction has been recorded as a method for the estimation of sulphanilamide by Werner [1] Ehrlich's diazo reaction is simple, and might perhaps form the basis of a method for determining the rate of excretion of sulphapyridine in the urine

CASE OF LATERAL SINUS THROMBOSIS

A. G TRESIDDER, C I E, M S LOND
MAJOR, RAMC , EAR, NOSE AND THROAT SPECIALIST AT A MILITARY HOSPITAL

WE now possess a good knowledge of the conditions in which the sulphonamides will prove of value, but they are still being given in a haphazard manner to cases in which there can be no justification for their use In particular, they are still being used in diseases of the middle ear and their complications when they should either not be given at all or only after appropriate surgical measures have been adopted One of these conditions is thrombosis of the lateral sinus, and the following case is an example

On Aug 18, 1941, a gunner, aged 36, came to my outpatient department with the history that his illness began six days previously with severe deep seated pain in the left ear and a generalised headache He had been given a course of sulphapyridine, after which the earache quickly disappeared and the headache lessened

When I saw him there was no complaint of headache or earache, but there was a profuse offensive discharge from the left ear He said he had had a discharging ear for many years Examination showed a swelling of the whole deep meatus, particularly of the superior and posterior deep meatal walls, so that only a portion of the tympanic membrane was visible , this was reddened and showed a pulsating perforation There was no tenderness over the mastoid process The temperature was 100 4° F , and the pulse rate 96 per min There was well marked deafness, the conversational voice being heard only within 6 in

He was admitted to hospital and exploration of the mastoid was advised, but he declined surgical treatment on the grounds that the pain in the ear had disappeared and the headache was only slight and occasional On the second day after admission he had a rigor, and the temperature rose to 104 4° F , the pulse to 128 per min The patient looked ill, and the tongue was dry and covered with a brownish fur A tentative diagnosis of lateral sinus thrombosis was made, and operation was urgently advised, but the patient persisted in refusing to have an operation, arguing that the treatment which he had already received had greatly improved his condition, and that now all he required was rest On Aug 21 there was a second rigor and his temperature rose to 103 4° F A blood-culture taken on this date was sterile. During the next two days the temperature did not rise above 99° F and there was no pain or mastoid tenderness, but the clinical signs in the deep meatus remained as described above From the 24th to the 30th there was only an occasional rise of temperature, and no more rigors Major D L Greig, RAMC, radiologist to the tion He also has amnesia for all that has happened from the onset of the attack A doctor called in to see him after two of these attacks felt sure that he must have had a severe heart attack, for his pulse was almost imperceptible and the extremities icy cold In spite of this his general health is excellent and a recent complete physical examination supported by X ray examinations of the skull and heart, a cardiogram, examinations of the blood and cerebro spinal fluid, and a blood sugar estimation have all failed to reveal any organic basis for the attacks The frequency of the attacks has been *lessened by full doses of phenobarbitone*

Traumatic Epilepsy

Besides being important in war-time, traumatic epilepsy is common in civilian practice, chiefly as a result of motor accidents

AFTER GUNSHOT INJURY

Figures of the incidence of epilepsy following gunshot wounds of the head are available from the last war, in 1920 the records of the Ministry of Pensions showed that out of 18,000 cases of such wounds 4 5% had developed epilepsy. In France Behague found epilepsy in 12 1% of 3523 cases These figures, however, do not distinguish between the incidence of epilepsy in wounds with, and wounds without, perforation of the dura mater Other statistics of the incidence of epilepsy after gunshot wounds of the head giving information on this point are those of Rawling, Steinthal and Nagel, and Credner and Wagstaffe All these observers are agreed in finding a greater incidence of epilepsy with wounds penetrating the dura mater

Thus Rawling reported *in a series of 452 cases of gunshot* wounds of the head of all types an incidence of epilepsy in 25%, and in 228 cases with penetration of the dura an incidence of epilepsy in 32 8% Steinthal and Nagel found an incidence of 28 9% in a total of 639 cases, and an incidence of 31 6% in 348 cases with penetration of the dura Credner gives an incidence of 38 2% in a total of 1990 cases, and of 49 5% in 1234 cases with dural penetration Wagstaffe's figures were an incidence of 9 8% in a total of 377 cases, and an incidence of 18 7%—nearly double—in 176 cases with dural penetration

Ascroft has recently published his findings in 317 patients receiving pensions for gunshot wounds of the head, the series excludes those who died as a result of their head injuries within 4 years, and those who received blunt injuries of the head and wounds of the cerebellum The series therefore comprises only the more severe types and contains a large proportion with wounds penetrating the dura mater He summarises his findings as follows

Of the 317 cases 107 (34%,) developed epilepsy Up to the end of the year 1940, 14 (4 4%) of the patients had died One and probably 2 others died of complications of the brain wound, the remaining 11 of intercurrent conditions In cases in which the dura had been penetrated fits were twice as frequent (45%) as in the scalp and skull wounds in which the dura was intact (23%) Scalp wounds due to missiles are more likely to be followed by epilepsy than are scalp wounds due to blunt injury There was no evidence that removal of metallic foreign bodies from the brain diminished the liability to epilepsy Prolonged wound sepsis, as indicated by delayed healing, favours the subsequent onset of epilepsy, both in cases in which the dura has been penetrated and in those in which the integrity of the dura has been preserved Epilepsy is more common after wounds affecting the sensoro motor cortex than after wounds of the polar region of the cerebral hemisphere The presence or absence of concussion (as judged by immediate unconsciousness) after gunshot wound does not influence the subsequent liability to epilepsy The first fit may occur within a few hours after injury, or may be delayed at least as long as 20 years Epilepsy begins more often in the first 2 weeks and thereafter the liability to epilepsy progressively diminishes In 30 of the 96 cases in which the course of the epilepsy is known fits ceased some years before the patient was last examined This subsidence of epilepsy occurred most often in cases in which fits began in the first fortnight after injury, less frequently when fits began within the first 2 years and never when the first fit occurred more than 2 years after the injury

Ascroft's investigation confirms the general opinion that epilepsy is more likely to develop after wounds penetrating the dura, but it is noteworthy that epilepsy developed in as many as 23% of cases in which the dura was not penetrated The types of epileptic attack included major convulsions without any obvious focal onset, attacks with a definitely focal onset in 31% of the cases and attacks of petit mal Accurate information about the date of onset of the epilepsy in relation to the date of wounding is given for only 84 of his cases In 56 of these epilepsy appeared within the first year, and in 19 of the 56 in the first month, of the remaining 28 patients, 10 developed fits in the second year, 4 in the third year, 4 in the fourth, 1 in the fifth, 6 between the sixth and tenth years, 1 between the eleventh and fifteenth years and 2 between the sixteenth and twentieth years after the original injury The site of the injury to the brain appears to have less influence upon the development of epilepsy than might have been expected, for though it is more common after wounds of the sensori motor cortex it may follow injury of any part of the brain, excluding the cerebellum, which rarely gives rise to epilepsy. Ascroft's findings may be compared with those in 343 craniocerebral injuries, reviewed by Wolf, in German soldiers surgically treated in the war of 1914–18 In 1941 traumatic epilepsy was found to be present in about 23 3 of these patients, 120 of whom had had perforating bone wounds

IN CIVILIANS

The incidence of epilepsy after injuries in civilian life presents a brighter picture, chiefly no doubt because most of these are closed and not penetrating wounds, but again statistics vary considerably

Thus Brun in 221 cases of civilian head injuries found an incidence of epilepsy in 8% Schou found 4 5% in 200 cases, while Feinberg in an analysis of 47,130 cases of head injuries reported to an insurance company between the years 1919 and 1933 discovered only 50 cases of traumatic epilepsy (about 8 cases in 1000) Rowbotham's recently published figures on the incidence of traumatic epilepsy after "blunt" *head injuries in peace time reflect, I think, the nearest* approach to present day normal figures in these cases Of a *series of 430, 11 developed epilepsy (2 5%) In every* case the injury had been received not less than 5 years before the inquiry was made The incidence of traumatic epilepsy is definitely less after civilian injuries than after the injuries of war, and if fits (probably due to extradural, subdural or subarachnoid hæmorrhage) developing within a few days of closed civilian injuries be excluded, the incidence of traumatic epilepsy becomes still lower The type of epilepsy developing after closed injuries of civil life is most often the major generalised convulsion

Thus Symonds found that of 28 cases, 24 exhibited generalised attacks, the attacks were at first of the minor type in 11 cases and became of a major type later I too have noted this tendency to progress from a minor to the generalised major convulsion in several cases In Rowbotham's cases 2 out of 11 patients showed attacks of the petit mal type only Fits with a strictly focal onset and a typical spread of the Jacksonian type are not common after closed injuries, but when seen they may be brought about by a contrecoup lesion A man recently under my care sustained a fracture of the skull in the right frontal region with a temporary *left* hemiplegia, 5 years later he developed typical attacks of Jacksonian epilepsy beginning always in the right hand Occasionally the attacks became generalised with loss of consciousness Since the attacks were not controlled with sedatives operation was carried out and the left motor cortex explored A cystic condition with cortical atrophy was discovered, clearly the result of an old severe contrecoup injury at the time of the original injury to the right side of the skull

Nevertheless, traumatic epilepsy may follow closed injuries of civilian life whether there has been a fracture of the skull, or not In 3906 cases of fractured skull collected by Feinberg, epilepsy developed in 19 (about 0 5%), in 16,762 cases without fracture of the skull he found epilepsy in 24 cases (about 0 125%) It thus seems that the chances of the development of traumatic epilepsy are increased by skull fracture The time of onset of epilepsy after the injury—the latent interval—appears to be much the same with the closed as with the penetrating injuries, if we exclude the uncommon cases in which fits begin a few days after the injury In most cases fits appear during the first year, after about 18 months the liability seems to diminish rapidly

It is not easy to decide exactly what factor or factors really determine the origin of the epilepsy With fits

0 5 mg for cattle In South Australia, sheep affected by the wasting disease prevalent there showed, in addition to the features of the Western disease, a progressive ataxia The pathological changes in these animals were similar to those seen in swayback in England Investigators were able to show that there were really two pathological processes at work, cobalt deficiency producing the signs as seen in South Australia, and copper deficiency producing the ataxia The lack of cobalt and, where it occurs, the lack of copper, may be made good by an occasional top dressing of the pasture with the appropriate salts

Mr W Lyle Stewart, MRCVS (Newcastle-on-Tyne), described *sheep "pining"* in Great Britain It occurs most commonly in the uplands near the Scottish Border, and is characterised by anæmia and emaciation The routine treatment by the sheep farmers is to transfer the affected flock for a short time to new pastures It had been found that affected animals were frequently heavily infested with parasites The possibility that a nutritional factor might be involved was, however, not excluded Analyses of the pastures showed that they were of poor quality, being especially low in calcium, phosphorus and, to a lesser extent, cobalt Therapeutic trials showed that treatment either with anthelmintics or with mineralised coke affected a reduction in mortality but that the beneficial effect of both treatments exceeded that of either alone.—Mr E L Taylor, DVSc (New Haw), pointed out that the evidence suggested that deficiency of cobalt lowered the resistance of the animal to infestation with parasites He compared this to the known lowering of resistance to infections in vitamin deficiency and stressed the importance of establishing whether in fact trace elements did have such an action —Dr Green, however, quoted work in North Wales from which it appeared that deficiency of trace elements and infestation could occur independently as well as in combination

* * *

The afternoon session, with Prof C R Harington, FRS (London), in the chair, opened with a discussion on *fluorine in human nutrition*—Miss M M Murray, DSc (Cambridge), who dealt with biochemical aspects of the subject, pointed out that fluorine was a normal constituent of teeth and bones, yet the effect of excessive amounts was to produce mottling of the teeth and osteosclerosis of the bones, especially the spine The commonest cause of mild fluorosis appears to be drinking water and the level above which effects are produced is about one part per million American work has suggested that mottled teeth are less prone to dental caries and work in England so far seems to bear this out Moreover sound teeth have been shown to contain more fluorine than carious teeth

Dr Dagmar Wilson (Oxford), in discussing the *clinical appreciation of fluorine distribution*, said it was likely that mottling of the teeth though mainly induced by fluorine, was affected by other nutritional factors Similarly, bony changes were not caused simply through fluorine intoxication but by the simultaneous action of nutritional factors or postural factors

Dr. Wilson also read a paper by Dr F H. Kemp (Oxford) on *radiological investigations* Osteosclerosis due to fluorine poisoning, seen fairly frequently in India, was characterised by tingling, pain and stiffness of the spine and often led to extreme cachexia or secondary infection. Radiologically, the spine showed synchondrosis and ossification of the transverse processes and of the intervertebral discs and wedging of the vertebral bodies In England, similar changes had been seen in the radiological examination of the spines of persons with mottled teeth and it was possible that these changes were also due to fluorine.

Mr Frederick Blakemore, MRCVS (Cambridge), contributed a paper on *industrial fluorosis of animals* in England Fluorosis which had first been described in cattle grazing near a superphosphate factory in Italy, had since been recognised in farm animals in many places Affected animals showed lameness, enlargement of the bones and cachexia. Smoke from superphosphate factories as well as glass works, brick works and aluminium factories contained appreciable quantities of fluorine The disease was more common in fields over which the smoke was carried by the prevailing wind Analysis of the urine and the bones of the diseased animals showed an increased amount of fluorine

The discussion on these four papers was opened by Mr C N Bromehead (H M Geological Survey) With Dr Wilson, he had examined areas in which fluorosis is known to occur, and so far the work shows that there is an association between the fluorine content of the soil or rocks and the occurrence of fluorosis

Dr H A Krebs (Sheffield) reported the result of an examination of workers in a fluoride factory Of 22 workers examined, 8 had evidence of osteosclerosis as shown, for example, by the high density of the bone In these cases, the fluoride excreted in the urine was also higher than in the normal—Dr H M Sinclair (Oxford) thought that the evidence was not conclusive that the osteosclerosis observed on routine examination was due to fluorine and Mr J D King, PhD (Millhill), said that in his experience fluorosis was associated not with less dental caries but with more.—Dr A C Frazer (London) asked if the fluoride in bone was as mobile as the calcium and whether parathyroid affected the turnover —In reply, Dr Murray said that the association of fluorosis with caries and with osteosclerosis observed on routine examination were by no means categorically established and more work was necessary

* * *

Mr W S Ferguson, AIC (Jealott's Hill), read a paper on *teart*, a molybdenosis of farm animals, which was found in 20,000 acres of Somerset as well as in many other parts It was characterised by excessive diarrhœa or "scouring," affecting cattle and to a lesser extent sheep The pastures were found to contain up to 100 parts per million of molybdenum, compared with the normal content of 5 parts per million The degree of scouring was proportional to the amount of molybdenum Old grass or hay were less toxic because less of the metal was in a soluble form Experiments had shown that the administration of molybdenum salts to normal animals produced a condition identical with teart. It was found that copper salts given as 2 g copper sulphate daily for 18 weeks were effective in controlling the disease —Mr S J Watson, DSc (Jealott's Hill), said that the Somerset war agricultural committee had issued copper sulphate to farmers this year and the results were very satisfactory —Mr E R Lewis suggested that the disease might also be controlled by growing legumes such as clover, which took up much of the element from the soil, or by making the soil more acid, since this resulted in less molybdenum being taken up by the pasture Mr K P Oakley referred to Vinogradoff's work on the molybdenum content of plants and animals The algæ of the laminaria group absorbed a great deal of the element and this possibly accounted for the large amounts of molybdenum in the lower lias

Miss E M Widdowson, PhD (Cambridge), read the last paper by Dr R A. McCance and herself on the *absorption and excretion of trace elements* To a large extent the elements behaved as one would expect from a knowledge of their chemical properties. Thus, if the diet contains substances which form insoluble compounds with the element concerned, less will be absorbed. An example is the effect of dietary phosphate or phytate on the absorption of calcium. Similarly, protein increased the absorption of calcium and magnesium because these metals formed soluble coördination compounds with amino-acids. Excretion by the kidneys was also determined by the solubility of compounds of the element It is difficult to determine the absolute amount of absorption of elements such as calcium, since apart from their occurrence in the food they were also secreted by the digestive juices; one could only determine the net absorption, that is the difference between the amount in the food and the amount in the fæces In some instances, one element might replace another of similar chemical nature; thus, lithium and sodium were to a large extent interchangeable Metals that form insoluble chlorides, such as silver and monovalent mercury, are not absorbed when taken orally since they are precipitated by the hydrochloric acid of the stomach Silver, however, may be absorbed from the mucous membranes of the mouth and nose and this accounts for the occasional cases of argyria seen to result from long-continued silver medication of these parts.—Mr. N L Kent, PhD, stressed that factors other than the chemical laws must hospital, reported that there was haziness of the mastoid cells on both sides, but the haziness was more definite on the left side On the 31st another rigor occurred, and rigors were repeated on Sept 1, 2 and 3, with accompanying temperatures of 104° F and 105° F On Sept 4 there was a very severe rigor and the patient now looked very ill There was a slight icteric tinge, his tongue was dry and furred, and his outlook, severely shaken by the repeated rigors, changed to one of anxiety, with the result that he volunteered to be operated on at once There was every reason for his anxiety because his general condition had much deteriorated since his admission to hospital 18 days previously Wasting was obvious, the facies was that of sepsis and the pulse was rapid and feeble

A Schwartze mastoidectomy was performed The bone was semi sclerotic, there was foul pus in the antrum, which communicated with a perisinus abscess The sigmoid sinus was exposed and opened and was found to contain a firm clot from the bend of the lateral sinus to the jugular bulb, but in no part had the clot broken down On account of the extension of the thrombosis to the jugular bulb, and because of the patient's antipathy to operative treatment which might lead to his refusal to undergo a second operation, I proceeded to ligature the internal jugular vein

After the operation the temperature rose only once to 100° F On Sept 18 the Schwartze mastoidectomy was converted into a radical mastoidectomy, and by Nov 18 the mastoid cavity had completely epithelialised, the hearing distance for conversational voice was now 12 feet No vertigo followed, and he was returned to duty

This acute exacerbation in a case of chronic otitis media well illustrates the type of case in which sulphonamides are contra-indicated as a sole preliminary form of treatment

I wish to thank Lieut -Colonel R H C Pryn, RAMC, officer commanding the hospital, for permission to publish this case

Medical Societies

NUTRITION SOCIETY

THIS society held their eighth scientific meeting at the London School of Hygiene on Oct 17 to discuss

Trace Elements in Relation to Health

At the morning session, the chairman, Mr J RUSSELL GREIG, PhD (Moredun Institute), gave a short *historical review* of the discovery of their importance by referring to the growth of our knowledge of the ætiology of pining in sheep Investigations over 100 years ago had concluded that the disease was not infectious but was related to the food Only after the conception of deficiency disease had become established was it thought that pining might be an example of dietary deficiency, and in 1922 the theory was advanced that it was due to a vitamin deficiency A few years later, the Australian disease of sheep, bush sickness, which was in many ways similar to pining, was said to be due to iron deficiency Similar conclusions were reached in England but further studies in Australia proved that the deficiency was one of cobalt Dr Greig stressed the possibility of the existence of partial deficiency of trace elements, analogous to the partial deficiency of vitamins

Mr H H GREEN, DSc (New Haw), discussing their significance in relation to diseases of *plants and animals,* said it was difficult to define clearly what was meant by a trace element The element appeared in a fairly high concentration in some organs and tissues and had an obvious essential function, like iron in the erythrocytes and iodine in the thyroid In other instances, the element was distributed throughout the tissues in small quantities so that it was difficult to say whether it had any function Other elements, such as copper, were essential in small quantities but toxic in large quantities Deficiency of copper and cobalt was well recognised in animals, and manganese, zinc, boron and fluorine also appeared to be essential Molybdenum and selenium on the other hand seemed to have only toxic properties

Mr R L MITCHELL (Craigiebuckler) talked of the distribution of trace elements in *soils and grasses* Unlike the major constituents of soils and rocks, the concentration of trace elements varied considerably, often as much as a million fold In igneous rocks, the trace element may gradually increase in concentration by chemical replacement of one of the other constituents It was more difficult to foretell the composition of sedimentary rocks The amount of a trace element in the soil which was available to the plant depended, with some elements, on the acidity or basicity of the soil, this meant that one could sometimes increase the availability simply by applying say ammonium chloride The amount taken up by a plant depended on the species but, for a given species, the ratio between the amount in the plant to that in the soil was fairly constant

Dr T MANN (Cambridge) in a paper by Prof D Keilin, FRS and himself on copper, zinc and other trace elements in relation to *physiological function and enzyme systems* suggested that the essential elements were those found in the ash of milk The first stage in establishing the function of a possibly essential element is to discover the compounds in which it existed in the body Copper, for example, was long known to form part of the molecule of hæmocyanin, the respiratory pigment of crustacea But in the mammal, it was thought to exist in the erythrocytes in an inorganic form But Professor Keilin and he have shown that it was present as a copper-protein compound, hæmocuprein This substance was found not only in erythrocytes but in the liver and in other tissues It also occurred in plants and was responsible for the darkening of the cut surface of plants as it was a constituent of the oxidase systems Zinc formed part of the enzyme carbonic anhydrase which played an important part in the transport of carbon dioxide and in the acid-base equilibria of the body. It was possible that zinc occurred in combination with other proteins forming substances with other actions The high activity of these metal-protein compounds could be judged by the fact that 0 1 μg of carbonic anhydrase, containing 0 003 μg zinc, could be detected biologically It was quite impossible to detect such an amount of zinc by chemical or spectrographic means Although deficiencies of the metal component of these protein compounds were well recognised, it was possible that deficiency also existed of the protein, if this were true, a fall in hæmoglobin might arise from such a deficiency even though iron was not lacking

SIR JOSEPH BARCROFT, FRS, opening the discussion, said that a definition of trace elements would have to include the following points first, they were usually metals but some (fluorine and iodine for example) were not, second, they were always found in the animal or plant concerned, third, they occurred in quantities of the order of one part in twenty thousand Finally he felt that the definition should include only elements of proved beneficial or toxic action, and exclude those whose occurrence appeared fortuitous —Replying to questions, Dr MANN said that there was evidence that, as in the vitamins of the B_2 complex, deficiency of one trace element might lead to signs of deficiency of another Thus deficiency of either copper or iron caused a decrease in hæmoglobin formation —Dr GREEN took up the question of defining trace elements raised by Sir Joseph Barcroft and others With our present knowledge, one could only say that they were elements which occurred in small quantities, they might have no known action or they might be beneficial or harmful

* * *

Prof THOMAS DALLING, MRCVS (New Haw), and Mr J R M INNES, DSc (Manchester), showed a film demonstrating the relation of *enzootic ataxia* or "swayback" of lambs in England to copper-feeding of ewes during pregnancy It showed the typical ataxia of new-born lambs, which might be severe enough to prevent them from keeping up with their mothers and so cause starvation The film also contained a demonstration of the lesions in the cerebrum and spinal cord

The paper on *cobalt and other trace elements in relation to disease in Australasia* by Sir Charles Martin, FRS, was read by Miss HARRIETTE CHICK, DSc (Lister Institute) These deficiency diseases occurred in Western and in South Australia In the West, the affected sheep or cattle showed a progressive emaciation, weakness and anæmia It was found that limonite, an ore containing iron, was effective in the treatment of the disease, but the curative agent was not iron, for an iron-free extract of limonite was as effective as the crude ore Experiment later showed that the active principle was cobalt and it is now possible to keep stock free from the disease by daily dose of 0 1 mg for sheep and about

THE LANCET

LONDON SATURDAY, NOVEMBER 7, 1942

INTRAMUSCULAR SULPHONAMIDES AND QUININE

TROUBLES with sulphonamides given intramuscularly have raised again the questions of technique which have been thrashed out many times for quinine. With the non-irritant injections, such as liver extract, no complications arise, though even there correct technique may save the patient pain at the time of injection and stiffness afterwards. Irritant injections are tolerated better by muscle than any other tissue, though THROWER[1] has demonstrated that local necrosis is common when the highly alkaline sodium sulphapyridine is given intramuscularly. Such sloughing, however, as a rule produces nothing worse than transient pain and disability. The serious troubles arise when the injected fluid reaches adjacent nerves. There was, for instance, the Trinidad case of ten years ago in which an injection of quinine into the buttock led to a sciatic palsy and a mighty legal battle ending before the Privy Council.

For the sulphonamides and antimalarial drugs the technique is much the same. The safest and least painful site is the upper and outer quadrant of the buttock, at the junction of the upper and middle thirds of a line joining the posterior superior iliac spine to the tuber ischii, well away from the sciatic and superior and inferior gluteal nerves. A sharp, fine-gauge serum needle is used—a hypodermic needle is not long enough—and needles should be periodically tested by applying a bending strain between hub and point. Needle and syringe must be clean and sterile; this is best achieved by boiling. If spirit or antiseptics are used they must be washed off before the needle is inserted. Injections should always be given in a good light. The patient will usually be in the semi-prone position with the upper knee drawn up. The injection site is painted with a coloured antiseptic. The syringe is then filled with the solution, a bubble of air being included which will be injected *after* the fluid. It is important not to leave an open track along which fluid may leak back, and the left hand therefore draws the superficial tissues downwards before the needle is inserted. The syringe and needle are held in the right hand as one holds a dart, the finger-tips gripping the hub of the needle and the nozzle end of the syringe. A fairly accurate estimate of the depth of the subcutaneous fat must be made, for the needle must reach well into the gluteal muscles. The needle is inserted with one quick stab but not beyond half an inch from the hub, the ulnar edge and little finger of the right hand acting as a stop. This half an inch is an essential precaution against the needle breaking, for any break usually occurs at the junction of the needle and its hub. Aspiration is then attempted to ensure that a vessel has not been entered, and thereafter the injection is given steadily and slowly followed by the air bubble to clear the needle. When the needle is withdrawn it should be inspected to ensure it has not broken. Consecutive intramuscular injections should be given on alternate sides. Some say that the buttock becomes less sensitive when injections are repeated, but it seems more likely that the patient acquires a higher threshold to discomfort. With sulphonamides and quinine, at any rate, this route should be used as little as possible. If an indolent ulcer does develop at the site of an unlucky injection the quickest way to heal it, once the acute illness is over, is to excise it under general anæsthesia and suture the wound without drainage.

There are usually urgent reasons for injecting solutions of the soluble sulphonamides. The patient may be unable to swallow, and in severe infections it may be necessary to supplement or precede oral by parenteral therapy in order to raise the blood concentration of the drug rapidly to an effective level. Intravenous medication has many advantages in these cases, principally because the peripheral circulatory collapse often present in the very ill causes local stagnation of any solution injected otherwise than into a vein. But if veins are collapsed or inaccessible there is no alternative to intramuscular therapy except hypodermoclysis, a procedure of questionable value. The sulphonamides given by injection fall into two main classes—those in which sulphanilamide is combined with a solubilising group to form neutral solutions, and the alkaline sodium salts of various derivatives of sulphanilamide. The first class includes the dye compounds, now largely superseded, and 'Soluseptasine'; the second group consists of the sodium salts of sulphapyridine, sulphathiazole, sulphadiazine, sulphacetamide and so on. Unlike the others of class 2, the sodium salt of sulphacetamide is neutral, but unfortunately its antimicrobic potency is low. The rest of the sodium salts are highly alkaline; sodium sulphapyridine for instance is as alkaline as N/10 caustic soda. The soluble derivatives of sulphanilamide are administered in solutions up to 10%, and up to 10 c cm can be given intramuscularly, but such a volume is painful merely for mechanical reasons however carefully the injection is given. The alkaline sodium salts are usually given intramuscularly in 33⅓% aqueous solution, and if danger is to be minimised not more than 3 c cm should be given in one injection; otherwise the pressure of fluid may lead it to track along the intramuscular planes to important structures.

Injection of quinine is called for most often in *Plasmodium falciparum* (subtertian, malignant tertian) infections. Coma in adults and convulsions in children are urgent indications. So are hyperpyrexia and the persistent vomiting which is common in the "bilious remittent" type of subtertian fever. Often in heavy infections although there is no vomiting the absorption of quinine appears to be slow and fever with headache persists; such cases respond well to a single injection of quinine. Intramuscular injection still is more popular than intravenous although for more than thirty years writers have urged the advantage of the intravenous route. Intravenous quinine has the theoretical advantage of bringing the drug into rapid and immediate contact with the parasite, but if given rapidly or in concentrated solution it may be followed by a fall of blood-pressure and by sudden death; locally it may cause thrombosis in a vein. Intramuscular injection has the disadvantage of being painful and of producing a local slough, which be involved in the absorption and excretion of elements For example, some people excreted manganese by the large intestine and others did not Plants too showed considerable differences in the amount of certain substances taken up from the soil He reiterated the importance of identifying the compounds in which the trace elements existed in the body, mentioned by Dr. Mann —Dr **MANN** said that by the use of radioactive isotopes it had been shown that iron and copper are converted into their organic compounds 4–5 hours after ingestion —Dr **MCCANCE** felt that the subject was fraught with difficulties and urged caution in the interpretation of the results of experiments with isotopes

---

[1] Thrower, W R *Lancet* 1940, i 967

Summarising the day's proceedings, Professor **HARINGTON** said that it was always difficult to prove the need of a specific element until it had been shown to be a constituent of a compound with clearly defined functions He cited iodine, which for long was thought by a few workers to be implicated in thyroid disease but only when thyroxine was isolated and its composition and action determined was the rôle of iodine generally accepted. In the same way the essential nature of copper and zinc were only fully realised when it was discoverd in what compounds they existed in the body

---

Reviews of Books

Subacute Bacterial Endocarditis

EMANUEL LIBMAN, MD, consulting physician, Mount Sinai Hospital, New York City, CHARLES K FRIEDBERG, adjunct physician to the hospital London Humphrey Milford, Oxford University Press Pp 108 15*s*

THE authors, with their wide experience, have written a concise and authoritative monograph on this important disease Ætiology, pathology, clinical features, diagnosis, prophylaxis, and therapy all receive adequate notice The most unorthodox and therefore most interesting part of the book deals with the mild and bacteria-free cases The authors believe that mild cases are common but often unrecognised The distinction between them and the bacteria-free cases is admittedly arbitrary Those which after recovery show no sign of the disease beyond the valvular lesion, present before infection, but suffer from sequelæ, are placed in the bacteria-free category The authors say that the bacteria-free stage may sometimes be suspected from the dark-brown colour of the face, and that sternal pain was present in all their cases—two clinical signs, which have received little attention from other writers They also draw attention to the little known fact that bicuspid aortic valves may be produced by the healing process They agree with most clinicians that though no satisfactory therapeutic agent has yet been discovered sulphapyridine is the best available but the percentage of cures is little higher than before the introduction of this drug They think that heparin used in conjunction with it is of little value and may even be dangerous, and do not consider the claim yet substantiated that better results are obtained with sulphapyridine and typhoparatyphoid vaccine than with the former alone Prophylaxis is stressed, especially the elimination of septic foci in those with well-compensated valvular disease or congenital heart lesions—a simple measure which might reduce the incidence of the disease appreciably

Allergy in Clinical Practice

By staff members of the Cleveland Clinic under the direction of RUSSELL L HADEN, MD, FACP, chief of medical division, edited by J WARWICK THOMAS, MD, FACP, chief of the section of allergy London J B Lippincott Co Pp 354 30*s*

IN this composite work the various manifestations of allergy are described in a clinical and practical manner The writers are specialists in various fields most of whom have not contributed much to published work on allergy before The idea is that each has studied allergy in his own field, and the book thus differs from those in which an allergist evaluates the rôle of allergy in some other specialist's field Allergic conditions discussed are bronchial asthma, hay-fever, perennial nasal allergy, allergic bronchitis, bronchiectasis, contact dermatitis, atopic dermatitis, drug eruptions, superficial fungous infections, urticaria and angioneurotic œdema, gastro intestinal manifestations, ocular manifestations, migraine and other allergic headaches, endocrine considerations and several uncommon manifestations In each chapter the symptoms and differential diagnosis are discussed lucidly, numerous illustrative cases are detailed in a concise and practical manner, the treatment outlined and the results summarised The importance, in all allergic cases, of combined management with inhalant, food and even bacterial antigens is stressed In hay fever skin testing with pollens alone is not considered sufficient; perennial inhalants and foods should be tried as well The fundamental rôle of allergy in the ætiology of mucous nasal polyps is maintained One or two chapters—for example, that on ocular manifestations—appear a little too enthusiastic even for an allergist.

Encephalography

E GRAEME ROBERTSON, MD Melb, FRACP, physician to outpatients, Royal Melbourne Hospital London Macmillan Pp 105 32*s* 6*d*

THIS short monograph presents the technique of encephalography and the interpretation of encephalograms concisely and clearly It is lavishly illustrated by clinical and pathological photographs, line diagrams, and reproductions of encephalograms, which fully justify its relatively high price The X-ray photographs are technically perfect and demonstrate lucidly every part of the ventricular system, basal cisterns, and sulci Dr Robertson follows the Swedish school of neuro-radiologists, and gives an illustrated précis of Lysholm's technique His work is simplified by use of the Schonander head table and the technique described can be translated to the general purpose units only with great difficulty Unfortunately the author only describes introduction of air by the lumbar route, although it is now widely held that more efficient ventricular filling is obtained by cisternal encephalography Abnormalities are well demonstrated after a description of the normal which includes an account of the asymmetry of normal lateral ventricles, particularly in the posterior horns

Cytology and Cell Physiology

Editor GEOFFREY BOURNE, DSc London Humphrey Milford, Oxford University Press Pp 296 20*s*

THIS is not a textbook of cytology but a collection of critical surveys of aspects of general cellular physiology and pathology in which fundamental advances are being made Each chapter is by an expert whose own researches have contributed substantially to progress in his subject Its production under war conditions is a remarkable achievement, and occasional minor defects deserve to be overlooked In the first chapter Dr J R Baker shows the importance of genuine histochemical methods and urges cytologists to think in terms of chemistry as well as of morphology His wide experience and enthusiastic interest in cytological technique should encourage a healthy scepticism in the interpretation of fixed and stained preparations Dr J F Danielli contributes two informative chapters on the investigation of cells by physical and physicochemical methods and on the cell surface and its properties in relation to cell physiology Dr J H Schulman summarises an immense amount of specialised knowledge on monolayer technique, but unfortunately has not introduced his subject in sufficiently elementary terms to make it easily intelligible to readers with slight knowledge of molecular properties Dr Bourne gives a clear and comprehensive account of mitochondria and the Golgi apparatus, and Dr M J D White summarises much fundamental information on nuclei, chromosomes and genes The results of micro-incineration studies are reviewed in detail by Dr E S. Horning Dr H Blaschko and Dr W Jacobson survey the scattered literature on the distribution of enzymes in cells and tissues This subject is in its infancy and the chapter should be easier to write in twenty years time, but it is critical and objective. In the final chapter, Dr R J Ludford discusses pathological aspects of cytology, it is a pity that the cytology of cancer, to which he has made such valuable contributions, should be dealt with in a short section and not in a separate chapter personalities were found to combine considerable resentment, frustration and anxiety with compensating efforts to bolster self-esteem by a show of independence and self-sufficiency - These emotions when excited consistently engendered the active changes described Finger temperature changes did not always closely follow changes in gastroduodenal function, nor was the relation between pain and increase in acidity and peristalsis always constant Psychologically it is often possible to demonstrate exact parallelism between periods of emotional stress and exacerbations of ulcer pain, and such stresses need not always be crises Ordinary strains may provoke intense effects because of the emotional make-up of the person, just as the difference between gastric reactions of ulcer patients and those of most normals suggests Emotional reactions and gastroduodenal changes should thus be viewed as two coincident aspects of behaviour in reaction to life situations—in some people relatively slight and harmless, in others so violent as to cause actual disease Insecurity, resentment, frustration and their opposites are closely linked with eating and the desire for food For the infant sucking at the breast offers the greatest sense of security, and even for the adult smoking or gum-chewing may sometimes give composure, reassurance and relief from tension Emotional states and the processes of eating and digestion are of course closely related, and this relationship has important bearings on the treatment of peptic ulcer as well as its ætiology The observations of Mittelmann and his colleagues are open to several criticisms, but we welcome the attempt to produce the laboratory link between psychological processes and gastric disease Their findings confirm the view that the personality of the subject is a fundamental factor in the causation of peptic ulcer

FAINTS AMONG DONORS

The blood donor who faints has an adverse effect on recruitment to an important form of national service And if the faint is delayed, as sometimes happens, until the donor has resumed work in a factory, it may lead to a serious accident Every effort should therefore be made to anticipate these undesirable reactions by finding out the most likely candidates and exploring preventive measures We are here dealing primarily with a physiological mechanism that is readily aggravated by psychological stimuli The physiological effects of acute blood loss were studied by Ebert, Stead and Gibson[1] in six professional donors who were in hospital for the duration of the study, 760–1220 c cm, representing 15 5–19 7% of the total blood-volume, amounts greatly in excess of the customary donation, were removed in the ordinary way and five of the donors showed sudden circulatory collapse Wallace and Sharpey-Schafer[2] obtained results of a similar order on 28 convalescent patients In both these experiments any gross emotional factors can be excluded with reasonable certainty A significant finding in the second group was a lowered blood-pressure after bleeding which, in eight of them, still persisted 24 hours later, in one case a fall of pressure with bradycardia and syncope occurred after the removal of 500 c cm, but half an hour later recovery was so far advanced as to permit the withdrawal of a further 600 c cm without significant change in the blood-pressure Poles and Boycott, who report their experience with the Army Blood Transfusion Service on another page, cite the instance of the two medical officers who fainted, one after the sixth and the other after the fifteenth donation Moreover when from 410 donors the amount of blood removed was 540 c cm the fainting rate was 8 5%, against 3 8% for a control group bled only to 440 c cm Fainting was not, as had been thought probable, confined to those normally showing an orthostatic fall of blood-pressure It seems clear, therefore, that fainting can be a purely physiological response to loss of blood

Most observers agree that collapse after blood-letting is common in the young, who are also more liable to emotional upset Greenbury[3] finds that young women, especially clerical workers, faint more readily than young men Others, including Poles and Boycott, have not found any tendency for females to faint more than males Williams[4] thinks that the tall thin asthenic type is liable to faint But in general, among the unemotional donors, it seems impossible to predict who will swoon Of the avoidable factors contributing towards fainting, fatigue seems certainly to be one, but its importance is not easy to assess It is a common experience that donors who hurry for their appointment are likely candidates for the sal volatile With regard to hunger, it seems agreed that donors who have eaten within three hours are less likely to faint than those who have not, but Poles and Boycott could not find convincing evidence that a lowered blood-sugar plays a part in the ætiology of fainting, and the prophylactic administration of glucose proved valueless Contrary to expectations they found the temperature and humidity of the room unimportant Neither did rate of withdrawal seem to matter Williams, however, urges the desirability of continuous supervision of the donor by the doctor, the fainting rate being reduced in this way from 8–11% to 3% He prefers not to bleed a donor during menstruation, and he describes the sudden onset of menstruation with an incapacitating exacerbation of dysmenorrhœa immediately after a donation, a phenomenon which he suggests may be ischæmic in origin The resemblance of the donor's faint to the vasovagal attacks described by Lewis has often been commented on, Brown and McCormack[5] considering the donors' attacks to differ only in respect of the horizontal posture and the loss of blood The possible rôle of the carotid sinus has been considered and it would be interesting to know if blood donors who faint have a hyperactive carotid sinus reflex Perhaps there is added justification here for the experienced nurse who insists on loosening the neckware of even the most robust and regular of donors However, carotid sinus hyperactivity is most commonly met with in the elderly, and in arteriosclerotics, only 2 of the 15 cases described by Weiss and Baker[6] being under thirty Ferris, Capps and Weiss[7] have noted fluctuations in the activity of this reflex and it has been analysed into if technique is faulty may become infected giving rise to an abscess, or may even be followed by tetanus In spite of the slow absorption by this route the small amount of quinine which is absorbed seems to be extremely potent in bringing about beneficial and often dramatic results Possibly the drug acquires additional therapeutic virtue by coming into contact with damaged tissues The intramuscular route is used of necessity in children when injections are required Abscess formation and pain can be prevented by careful technique Quinine dihydrochloride is the salt used for injection and it is preferable to use sterile ampoules of the solution when available There are reliable ampoules on the market containing gr 5 and 6 in 1 c cm and gr 7 and 10 in 2 c cm of water The solution may, however, be prepared fresh and sterilised by boiling Quinine dihydrochloride is soluble 1 in 0·6 of water It may also be made up as gr 7 in 3 c cm of normal saline The most important point in technique is to ensure that the syringe is sterile , with this precaution the incidence of abscess in one colonial hospital has been less than 1 in 5000 The solution, which is of a syrupy consistence, is injected very slowly to avoid pain, taking two or three minutes A hasty injection is usually followed by agonising cramp travelling down the leg Local massage after injection is painful and unnecessary The dose and frequency will depend on the particular case Relatively large doses are given to children because the drug is absorbed slowly and hence will have a prolonged action Five grains can be given to an infant In adults, in severe cases, 10 or 15 grains should be given at once Ten grains should be repeated six-hourly in cases of coma for 3 or 4 doses The site of injection should be varied each time In milder cases a single injection of 7 or 10 grains will often stop vomiting, relieve headache or reduce the temperature when full doses are given by mouth as well Mepacrine injections are best given intramuscularly, the dose being 0 05–0 1 g They do not cause sloughing and absorption is rapid Toxic symptoms including mepacrine " psychosis " are frequent after large doses intravenously, and delayed collapse and sudden death after 12 hours have been recorded The drug compares favourably with quinine in its effect on the fever and parasites, though extravagant claims were made in its early trials Both mepacrine and quinine have been subject to abuse by giving injections indiscriminately—often with the sole object of gain and even in cases when the diagnosis of malaria was not established This should not be allowed to obscure the fact that both drugs are safe and efficacious when given intramuscularly within the correct indications and with good technique.

EMOTIONS AND GASTRODUODENAL FUNCTION

THE association of peptic ulceration with the nervous system has long been recognised, but there have been few experimental observations on the relationship of the emotions to gastroduodenal function, partly because of difficulties in assessing emotional states and excluding personal bias in the observer The experimental approach, too, has been baulked by the persistent idea that " functional " and " organic " conditions are separate, rarely meeting and never mixing An increasing volume of work on the psychosomatic aspects of medicine is showing how false such a separation must be ' The question is no longer Has this patient an organic lesion or a neurosis ? but Which of the two is the primary condition since both are present ? British medicine has attached importance to the underlying nervous constitution and the significance of anxiety and strain in the ætiology of peptic ulcer, but most studies on this subject have correlated personality types and occupational stresses with the incidence of such ulceration

MITTELMANN and others [1] in America have now set out to relate emotional states to actual changes in gastric motility and secretion Normal subjects and patients with peptic ulcer were examined under controlled conditions in which some 160 observations were made The subject swallowed a double rubber tube, to one orifice of which a thin rubber balloon was attached , this was inflated in the stomach and the tube leading from it was connected to a kymograph by way of a water manometer, and gastric contractions were thus recorded The second tube was open and gastric juice was withdrawn through it by continuous suction Movements of the chest wall and variations in finger temperatures were also recorded The same subjects were repeatedly examined and, after control periods during which as much mental and physical relaxation as possible was achieved, several experimental periods were studied during which the emotions were excited in different ways The mental stimuli applied, judging from previous study of his character and personality, were such as to challenge or undermine the subject's sense of emotional security and to reinforce old stresses The type and intensity of emotions induced by carefully chosen situations or questions naturally varied from subject to subject, and their physiological changes in gastric secretion and motility naturally differed too, even during periods of apparently complete relaxation , but allowing for this the subjects showed remarkably consistent reactions to the emotions engendered Tension, anxiety, resentment and anger were almost always accompanied by increase in secretion of hydrochloric acid and pepsin , peristaltic activity became continuous and the contractions increased in size , the respiration-rate became more rapid and breathing shallower and there was usually a drop in finger temperature These reactions were seen in subjects with and without ulcer , but in the ulcer patients pain often developed as well, and the changes on the whole were ampler When feelings of security and assurance were induced, however, gastric function reverted to normal The observers suggest that besides these variations in secretion and motility under emotion, changes may be found in gastroduodenal vascularity , thus in conditions of induced anger and resentment they saw the blood-vessels of a gastrostomy patient dilate This implies a direct relationship between such changes and mucosal erosions or actual ulceration

When the responses of the normal subjects investigated were closely analysed, some contradictions were noted In some people emotional stimuli may cause gastric inhibition rather than stimulation, and in these fear rather than resentment seems to be the dominant feeling Among the peptic ulcer patients no case of such inhibited action was noted , and their

WHY DOCTORS DIE

THE medical profession has its hazards, as Dr A Hope Gosse, in his presidential address [1] to the Medical Society of London on Oct 26, was able to show from records of 8884 doctors and dentists in 1938 They ranged in age from 25 to 65, and all had been examined and found physically fit when they first came under observation He divided them according to age, there were 2411 aged 25–35, 3604 aged 35–45, 1799 aged 45–55, and 1070 aged 55–65 In 1938 there were 8 deaths (0 33%) in the first of these age groups, 9 (0 24%) in the second, 8 (0 44%) in the third and 16 (1 5%) in the fourth The figure 8 seemed high for the first age group, and an analysis for the corresponding age group in 1939, made on about the same number of doctors, gave only 3 (0 12%) deaths, which he thought to be a fairer figure With this correction there is, as might be expected, an increase in the death-rate with each decade in the proportions 1 2·4 13 He estimates that 3 out of 4 doctors survive to 65, however, which gives most of the profession a chance to shine later as grand old men Seeking the causes of death in those carried off earlier he examined 100 consecutive deaths among his 8884 doctors between 1938 and May, 1940 Cardiac and cardiovascular diseases accounted for no less than 33, in 17 of these the condition was cardiovascular degeneration, and in a further 10 coronary thrombosis But he does not believe that coronary thrombosis has any claim to the title of "the doctor's disease" which some have given it Where, he asked, is the evidence that any other profession or trade has a lower rate than 27 deaths from cardiovascular degenerative diseases out of 100 deaths before the age of 65? Malignancy accounted for 15 deaths out of his 100 and pneumonia for 12 Hemiplegia—which might perhaps fairly be added to the degenerative cardiovascular conditions, bringing the total up to 36%—was responsible for 9 deaths No less than 7 committed suicide, 5 were killed in accidents and 4 died of pulmonary tuberculosis Infections, which might be supposed to come the doctor's way fairly often, only killed 11, and the remaining 4 died of prostatic disease, a blood disease, a perforated duodenal ulcer and enemy action

During 1938, 1620 of the 8884 doctors in the series were ill for over a week, influenza and other respiratory infections were the cause in 648 (40%) of them, including 21 cases of pneumonia Other acute infections affected 76, so that infections if relatively poor at killing doctors are good at wasting their time, 100 (6%) were laid up with accidents, 11 with insanity and 60 with anxiety states, 78 with fibrositis or other rheumatic disorders, 54 with appendicitis, 51 with infections of the hand, 18 had pulmonary tuberculosis Only 57 went to bed with heart or cardiovascular trouble, which possibly signifies that if doctors with cardiovascular degeneration would lie up a little earlier, it would not loom so large as a cause of death in the profession On the whole Dr Hope Gosse finds that every doctor must expect an average of 8 6 days of illness a year between the ages of 25 to 65 In 100 consecutive doctors who had reached the age of 65 he found only 7 who had not had seven days of consecutive illness during their working lives, he did not mention whether they felt proud or aggrieved

REMEDIAL EXERCISE TECHNIQUE

THE physical process of getting an injured man's muscles back into trim is only one part of reconditioning but it is an essential part, and one of the most valuable lessons of the British Orthopædic Association Nottingham meeting was Mr E A Nicoll's demonstration at Berry Hill Hall of the principles embodied in remedial exercises and occupational and recreational therapy The work in a rehabilitation centre must be varied in character, or the patient soon gets bored There should be general exercises to build him up and make him fit, but this must be constantly alternated with specific exercises for the actually disabled part We now know that the dosage of remedial exercises is very important, and there is as much danger in a "poisonous dose" for fatigued muscle as if the exercise were some potent drug It is therefore important to try and assess what is the optimal dose of exercise for each man, after which he must relax This hiatus is filled by occupational therapy, which is purely diversional and intended just to keep the patient interested, although many people think that because they have an occupational therapy department they are doing all that is needed for rehabilitation General exercises, such as running, are not enough, and at certain times full and undivided attention must be given to exercising only the disabled part There are three principles to be observed in any such specific remedial exercises (*a*) the exercise must be really specific, and the patient has to be watched or he is apt to develop a trick movement, (*b*) there must be rest intervals between exercises, and (*c*) the exercises must progress—that is, they must be kept just a little ahead of the patient, as Nicoll put it, like the donkey and the carrot held in front of him—but the patient here eventually gets the carrot Progression of movement in three ways is required, in range, power and time Men who have to work, say, in the mines work under conditions of great physical stress, and have not only to have powerful muscles but must be able to keep working over long periods, and such a patient must be capable of long sustained powerful exercises before he returns to duty Each of the exercises is so arranged as to progress gradually To take one exercise as an example, in an extension exercise of the back the patient first lies on his face with hands at the sides and feet held, and he lifts his head He now puts his hands behind his ears and raises his back He next extends the arms in front of him and raises himself, thus lifting the additional weight of his arms He then progresses in range of movement by lying over a small chair, and then extending his back For flexion, lateral flexion, rotation—for each movement—such progression exercises have been planned Nicoll points out that a muscle only increases in power if made to contract against slightly increased resistance, and the next principle therefore is to isolate the muscle and make that contract, this he does by the use of pulleys and weights To exercise say the adductors of the thighs, the whole limb is first suspended to an overhead frame To the inner side of the thigh a cord is attached which leads to weights over pulleys, and the patient can then adduct increasing weights for longer and longer periods A graph of this can be drawn, and the patient sees for himself his regular progress Nicoll has come to know the amount of weight, and how long it must be maintained, before a miner can return to work—for a knee injury the miner must be able to pull up and hold 22 lb ten times without being unduly fatigued All these exercises must be slowly performed The X-ray plate is no reliable guide to subsequent efficiency Some of the miners with well-marked spinal deformity after crush injuries had remarkable flexibility and movement in their spines The flexibility of any miner's spine is always striking, Nicoll explained it as due to the specially long hamstrings they possess from working in the mines from the age of 14 They can thus touch their toes with the palm of their hand, often even when also slightly flexing the elbows Nicoll's planned scheme of exercises built on sound principles so as to progress step by step represents a great advance Up to now, the average medical man has had too little knowledge of the principles he should employ in guiding his massage department or physical instructors [1]

[1] Three useful books on this subject are published by H M Stationery Office (1) Physical and Recreational Training 1941 1*s* (2) Recreation and Physical Fitness for Youths and Men Board of Education Physical Training Series No 15 1937 2*s* 6*d* (3) Reference Book of Gymnastic Training for Boys Board of Education Reprinted 1938 3*s* 6*d*

three components a vagal stimulation, a depressor action, and an effect on the cerebral vessels causing local anæmia of the brain BROWN and MCCORMACK suggest that the carotid sinus may be only one of several receptor organs and that the syncopal attacks of donors may be induced by the same efferent pathways It is perhaps significant that the three components of the carotid sinus reflex have been recognised either severally or together in the syncope of donors Some of these syncopal attacks are associated with convulsions and occasionally with loss of sphincter control When the attack is followed, as it sometimes is, by a deep sleep, the resemblance to an epileptic fit is complete Can it be assumed that these donors are potential epileptics and that the loss of blood has induced a first attack ? An embarrassing and fortunately rare sequela of a faint is acute hysteria, which calls for firm handling ; these people should be allowed to faint only into the arms of one of their own sex Another interesting complication of blood letting is hyperventilation tetany, seven instances of which have been recorded by FRAZER and FOWWEATHER[8] This state, which has sometimes developed after the removal of only a small amount of blood, is associated with a low inorganic phosphorus content of the blood and a high normal or raised calcium They attribute these attacks to fear, but mention that the small amount of adrenaline in the local anæsthetic may play its part

War-time experience in mass bleeding has taught us that it is possible to make the nervous donor feel at home The apprehensive subject who has volunteered for self disciplinary or purely altruistic reasons, or who has been pressed into service by an over-zealous propagandist, should never be left unattended and mentally unoccupied With encouragement he will make a good donor Volunteers awaiting their turn should sit in a separate room, where their hæmoglobin can be estimated, a procedure which apart from giving both doctor and patient added confidence invariably creates interest and diversion A not too obtrusive background of music both here and in the bleeding room serves to dispel fear and monastic gloom, while the minimum of theatre ritual consistent with asepsis helps in the same direction The bleeding room should be airy and light and beds are more comfortable than couches It seems best not to screen off each donor for there is comfort in the knowledge that others are going through the same ordeal , the bogy of epidemic fainting can be obviated by having the beds in series A nurse should engage the attention of the donor until the doctor arrives POLES and BOYCOTT have tried giving donors from hot workshops a litre of normal saline before bleeding , in a group of men over 40 the fainting rate was thus reduced from 2 9% to 0 8% If such donors have to be bled straight from work this measure seems desirable, but for choice donors should be bled in their off-duty time The pressure in the sphygmomanometer cufflet, which causes less discomfort than a tourniquet, need never exceed 80 mm Hg, and once the flow has been established can be reduced to 40 mm or less , many will fill their bottles with no pressure at all The amount removed should never exceed 420 c cm and should often be less The donor should remain on the bed for 15 minutes at least and not be taken through another room unless he can be carried on a stretcher After refreshment he should rest in a chair and not be allowed to leave the building until at least half an hour has elapsed since completion of the bleeding Such measures will not abolish faints but should reduce their incidence to under 2%

Annotations

CAMP-FOLLOWERS OF WAR

IN his broadcast on Oct 23, Sir Wilson Jameson coupled tuberculosis and venereal diseases as infections which normally become more prevalent during wars, and he asked for a frank and realistic attitude to them on the part of the public Developing this theme at a recent press conference he pointed out that, while our national health during this war has been better than could have been expected, these two groups of infection have shown the anticipated increase It is noteworthy, however, that the rise in the death-rate from tuberculosis has shown a remission during the first half of this year, deaths from all forms of the disease having numbered 14,412 as compared with more than 16,000 deaths in the first half of 1941 Nevertheless the figure still maintains a substantial lead over 14,131 deaths, the figure for the first half of 1939, and a further rise, as Sir Wilson was careful to point out, must be expected In the case of venereal diseases the rise in incidence has been steady, though not as rapid as it was in the last war Before this war the numbers of new cases of syphilis attending clinics had fallen from 9000 in 1931 to just below 5000 in 1939 In 1941 the figure rose to 7332—a 50% increase among civilians , if Service cases are added the increase is about 70% Since venereal diseases are not notifiable in Britain this is just a rough estimate, but a fairly close one he believes Figures for gonorrhœa among the civil population are more difficult to assess, because many cases are treated privately, but working on figures provided by the Forces it can be assumed that there are 8 new cases of gonorrhœa to each new case of syphilis This would mean some 60,000 new cases of gonorrhœa last year among civilians The problem is neither overwhelmingly large nor beyond the scope of existing provisions for treatment There are, he reminds us, 200 treatment centres in England and Wales, mostly at hospitals, and in country districts general practitioners specially trained in diagnosis and treatment are under taking the care of cases in their surgeries , so that therapy is available for anyone who needs it—and in early cases of either syphilis or gonorrhœa, the recovery-rate under treatment is nearly 100% He believes that if these diseases were discussed more generally and frankly, as infections which can be cured, people would more willingly attend for early treatment The Scandinavian countries have reduced the incidence greatly by airing the subject of venereal diseases thoroughly, and encouraging realism in the public attitude to it In Sweden in 1935 the incidence was only 0 6 per 10,000, at a time when it was 1 2 per 10,000 here He thought there was little to be gained at this stage by emphasising the more dreadful side of these diseases or exaggerating the danger to wives and unborn children , but he is anxious to see the whole topic removed from its association with notices in public conveniences and discussed in the context of an infection which is spreading and can be checked

The Ministry is also appealing to practitioners to make sure that in treating gonorrhœa they use adequate dosage at the start The quicker the patient is cured the less chance he has of spreading disease, of defaulting before he is fit, or of developing a blood dyscrasia , and the less the danger that the gonococci will become drug resistant

SONNE DYSENTERY AT A GRAMMAR SCHOOL

JOHN R GRAHAM, M B ST AND, D P H
MEDICAL OFFICER OF HEALTH FOR CHESTERFIELD RDC

THIS summer there was an outbreak of Sonne dysentery in a mixed day school of 301 pupils who come from a ten mile radius Practically all the children have lunches prepared and served from the school kitchen. The headmaster's wife supervised the kitchen staff, which consisted of a cook and four kitchen-maids One of the maids had only returned to duty after scarlet fever the day after the outbreak started The first report of the outbreak was from a local practitioner on the evening of Wednesday, July 8 This doctor, whose son was one of the patients, learned from the headmaster that a number of children were absent on the morning of that day and a further number had been sent home during morning school with sickness and diarrhœa One girl had been absent sick on the previous Monday with a diagnosis of dysentery not subsequently confirmed One boy sent home on the Tuesday with sickness and diarrhœa returned to school on Thursday This boy was perfectly normal when interviewed on Thursday. It was not possible to obtain a specimen of fæces and the history, while suggestive of a mild Sonne infection, was far from conclusive On Wednesday morning 15 pupils were absent and during the day a further 23 were sent home suffering from sickness and acute diarrhœa One of the kitchen-maids also complained of feeling ill on Wednesday morning but felt better in the afternoon This maid was absent on Thursday morning, and was found to be suffering from a typical attack of dysentery A positive stool was later obtained from this case The two local practitioners reported no outbreak of sickness and diarrhœa in the town, the only cases at this stage being from the school

On the Thursday morning (July 9) 14 more pupils were absent, all presumably suffering from the same complaint This gave a total of 52 cases in two days out of a total of 301 pupils It is certain that some of the pupils still attending had modified attacks but would not admit to it, as the school-certificate examinations were being held, and to miss this examination meant another year at school

Specimens of fæces from 5 of the worst cases were obtained on July and taken *direct* to the Derby County Council Laboratory It is important that specimens of stools should be sent with the least possible delay, if there is a long period between collection and plating out the Sonne bacillus tends to lose virility and be ousted by the hardier and quick-growing coliform organisms All 5 cases were reported to be positive for Sonne dysentery on Friday, July 10 Before this report was received it was obvious that some article of food partaken by the children must have been heavily infected, and the one meal taken by all the children was lunch The following are the menus

Friday, July 3 Stewed steak, new carrots, new potatoes

Monday, July 6 Roast beef, spring cabbage, new potatoes, gravy, treacle sponge and custard

Tuesday, July 7 Cottage pie, date pudding and custard

Of the 15 pupils absent on Wednesday the earliest symptoms appeared at 11 PM on Tuesday, giving a possible incubation period of 10–36 hours if Tuesday's lunch were at fault and 34–60 hours if Monday's lunch was the culprit

Investigation —All materials from lunches on July 3 and 6 had been used up Samples of cottage pie and date pudding of the lunch on July 7, as well as specimens of milk, water, custard powder and flour were examined, all with negative results The farm supplying the milk to the school was visited and no history of any intestinal disturbance was admitted by any of the workers It was highly improbable that this milk was infected as the farm had a large retail milk round and no outbreak occurred among their customers Specimens of fæces from the kitchen staff, and blood specimens were obtained and yielded negative results No history of any illness before Wednesday, July 8, was admitted by any of the kitchen staff It is to be noted that negative agglutination reactions in the dysenteries are not always reliable[1] Hobbs and Allison report in the July *Bulletin of the Emergency Public Health Laboratory Service* of two carriers who failed to agglutinate Sonne's bacillus at 1/10 or over

Preventive measures —The school lunches were stopped after Thursday, July 9 The school caretaker was instructed to wash with disinfectant all lavatory seats, cistern handles, taps, &c, and to have all towels boiled

Secondary cases —Fifteen further pupils were absent on Friday, July 10, and 8 more on Monday, July 13 It was not possible to visit all these cases but some at least were not suffering from dysentery but stayed away from fear of contracting the disease Four secondary cases were known to occur in households of infected pupils

Mode of infection —It is highly improbable that any of the well-cooked dishes were the infecting agents It was found that the custard served with the pudding was prepared with milk and custard powder This custard was made about 1–2 hours before being served and in the interim was kept warm on a rack or in an oven This is the most probable food to be infected. It is likely that one of the kitchen staff had an extremely mild infection or had fortuitously contaminated her hands and in handling the custard had inoculated it

Type of attack —The attacks varied greatly in severity, but most of the patients had fairly severe and acute attacks The following history may be taken as typical

Boy, aged 12 yr Woke with pain in stomach at 6 AM on Wednesday, July 8 Vomited and had four very loose motions before going to school Vomited again in school and was sent home, where he arrived at 11 AM Had violent headache and was sick again Started at 2 PM with diarrhœa, had a violent motion every half hour till 4 PM Some blood and mucus in stools Then became drowsy and "wandered in his mind" Was very "fevered" At 10 PM diarrhœa started again and continued till 4 AM with motions nearly every half hour He then slept and next morning had one or two loose stools but was much improved When seen on Friday, July 10, temperature and pulse were normal The patient felt and looked tired and complained of "heaviness in his head"

Headache in this period was a common complaint with most cases Temperatures of 102°–104° F were common in the more severe cases, and the urgency was so great that in some cases it looked as if there was loss of sphincter control There were no fatal cases and all made uncomplicated recoveries

CONCLUSIONS

The epidemic was of a typical dysentery with sudden onset This is in contrast to the outbreak at Ely Homes for Children, Cardiff, reported by Hobbs and Allison The outbreak was certainly caused by some article of food served for lunch at the school, but, as in so many of those outbreaks, it was impossible to prove conclusively which dish was responsible and how it came to be infected

---

ROYAL MEDICAL BENEVOLENT FUND —The management committee met on Oct 27 to receive a very encouraging report There has been a slight decrease in subscription income during the past nine months and an increase of approximately £1000 in the amount paid in grants, but the treasurer was cheerful about the situation A number of welcome legacies were announced, but attention was again called to the difficulties caused by benefactors not being clear as to the name of the body to receive their gift Such inaccurate descriptions as "British Medical Benevolent Fund" give rise to confusion Sir Thomas Barlow, in celebration of the 25th year of his presidency, has sent a personal letter to the staffs of hospitals asking for their cooperation, and the result has been encouraging His Christmas Gift appeal, now an established success, should enable the fund to give at least the usual £2 to each of its beneficiaries—a godsend to many of the deserving people who depend on the fund The case committee reported that in view of the increased cost of living it had taken advantage of the encouragement to be more generous in its grants so far as could be done with prudence

APPOINTMENTS FOR OUTPATIENTS —An appointments system for outpatients will be instituted at St George's Hospital on Nov 2 Private and panel doctors are asked to coöperate by telephoning to arrange appointments with the appointments clerk at the hospital (Sloane 7151)

RCS CALLING

SURGERY comes into its own during war when breakages cannot be replaced from stock and invisible mending becomes nine parts of the craft Orthopædic surgeons especially have been thinking of that restitutio ad integrum, rather feebly called rehabilitation, which should have been, and too often has not been, the aim of the healer The Royal College of Surgeons of England has never failed in its collegiate devotion, witness the attendance at council meetings which has not been diminished by the present fatigues and hazards of travelling, and the gulf between fellows and members is bridged by a pleasant communal meal in the autumn. There are other signs too of a more catholic outlook The college has joined the other two royal colleges in a standing committee which meets at least once a quarter to consider big common issues This committee has defined consultant status and has suggested that those who claim it should have had proper training and experience One change is so fundamental that it is legitimate to fancy it blew in (and up) with the bomb on the Hunterian museum Surely John Hunter, who was always asking how and why things happen, would have rejoiced to learn that pathology is now to be included in the first test exam for the surgeon Deans of medical schools had agreed that the Primary Fellowship as it stood was non-educative in character and wrongly delayed the entry of the undergraduate into the wards The examination is therefore to be made postgraduate, which will please the overseas candidates, and Home Office permission is being sought to make the necessary alteration in the by-laws This worldwide distribution of the fellowship is in itself significant, candidates from overseas made up 43% of the entries to the Final Fellowship in the last prewar year Besides the brave scheme for the restoration of the museum some small but useful facilities have been granted Medical students are now free of the library to which many new textbooks have been added for their needs Textbooks and periodicals have been supplied to the Prisoners of War library, and 22 medical journals are circulated among the officers of Royal Naval hospitals A research chair in ophthalmology is being set up at the Royal Eye Hospital The report which tells these and many other things can be had on application to the secretary of the college at Lincoln's Inn Fields Fortified by reading it any fellow or member can propose (before Nov 9) a motion to be brought forward at the annual meeting of fellows and members to be held at 2 30 PM on Nov 19 But for the last five years attendance at this meeting has not reached the quorum of 30

POLIOMYELITIS AFTER TONSILLECTOMY

CASES in which poliomyelitis has followed tonsillectomy within 7–14 days have been recorded from time to time since 1910 A total of 2857 such cases has now been collected by Aycock[1] and his analysis shows that the bulbar form of paralysis has followed this operation in a significant proportion of cases The evidence points to the contamination of the wound by virus existing locally at the time of the operation rather than by subsequent infection A remarkable example of this association is reported by Francis and his colleagues[2] In a family from Akron, Ohio, 5 of the 6 children underwent tonsillectomy on the same day Between 9 and 14 days later all 5 developed a severe bulbar poliomyelitis from which only 2 survived Investigation of possible sources of infection disclosed the virus in the intestinal tracts of certain child contacts of the family as well as in the 6th child who had been fortunate enough to escape tonsillectomy Virus was not obtained from the parents' stools It seemed probable that the children of this family acquired the virus in the first place from a cousin with whom 2 of the children had stayed for several weeks, a month before tonsillectomy was performed This cousin, a child of 5, had undergone tonsillectomy 2 days before the visitors left for home, and had an attack of "general weakness" 3 weeks later which, in retrospect, may well have been a mild attack of poliomyelitis He and his younger sister both harboured the virus in their intestinal tracts The disease was *not prevalent locally* at that time and the conclusion seems inescapable that tonsillectomy precipitated the simultaneous attacks in the 5 children, especially as the palsies were all of the bulbar type and the axonal pathway is now generally accepted as the usual mode by which virus reaches the central nervous system We have yet to learn how the virus is conveyed from one carrier to another, from the investigations of these workers it seems clear that "something more than contact must be invoked to explain the distribution of virus"

CONTROL OF TUBERCULOSIS

THE sections of medicine and epidemiology RSM last week agreed that pulmonary tuberculosis as an infectious disease could only be brought under control by a threefold approach, clinical, sociological and epidemiological. Dr R C Wingfield, opening, was for a long-term policy which 50% of his audience would not live to see completed The sputum-positive members of the community, computed in Britain at 250,000 with many of them subjectively well, were the spear head of an infectious army which had to be annihilated Later speakers *suggested how this might be done* Wing-Commander R R Trail said it was essential that a patient on leaving sanatorium should be well enough off to carry out the instructions given him Dr Cyril Banks wanted the tuberculosis officer to be epidemiologically as well as clinically minded

In recent months it has become clear that action will be based on three principles (1) mass radiology for the detection of early cases, (2) accommodation for those requiring treatment with financial provision for both patient and dependants, (3) an acceptable rehabilitation scheme whereby, through part-time work and subsidised wages, a patient can be nursed back to normal employment and relapse avoided The encouraging statement of the Minister of Health has left open two questions first, what is the size of the financial grant that he is going to make to a patient, and what is his definition of treatment? If by treatment is meant institutional treatment only, then the grant will presumably cease the moment a patient leaves his sanatorium and the inducement to attempt unsuitable work will remain On the other hand, if the recommendation of the MRC committee on Tuberculosis in Wartime that rehabilitation should be regarded as an *essential part of treatment* is accepted, then a big step will have been taken towards remoulding the patient's environment along the right lines rather than forcing the patient to fit the external conditions The importance of the environmental factors, of which infection can be regarded as one, in any scheme for the eradication of tuberculosis was again emphasised by Dr J B McDougall Moreover it is important that these three measures—mass radiography, *financial provision* during treatment and rehabilitation—should march in step There is a danger at present that the first may outstrip the other two, that fresh early cases will be detected before the machinery to deal with them is ready This would mean the loss of public confidence on which ultimate success rests Surgeon Captain W D W Brooks insisted that control should be international in outlook ' *It would be futile, if not dangerous,* to breed a Mantoux negative race of non-immunes, with the risk of influx of infection from a neighbouring state the archbishop is a candidate for the post of prophet he will have to contend with the same difficulties, but, please God, humanity will cast aside its childishness and scan the message and not the man

The season of sleepy wasps was upon us I had been reading both in the medical and the lay press of the dangers of being stung on the head or neck by such an one, of, for example, a labourer who had felt a prick on his forehead, had brushed away an offending insect to fall down, some ten minutes later, dead Had I not seen a yellow cocker spaniel bitch roll over in a syncope as the result of a wasp-sting? True my only encounter in 60 years with a wasp was *more humorous than painful* She resented my intrusion into her winter quarters—a pair of beautiful blue trousers which she, woman-like, had chosen with an eye to colour schemes But that sting was on a foot and not on my head or neck.

And then it happened I felt a prick quite close to my left jugular My colleagues, regardless of entomology, shouted "kill him" as the insect fell on the table-cloth Doubtless I went white, and rushed off to the laboratory for the one per cent. acetic acid I knew I should find there, having read that it was an antidote to the pain of wasp-stings It worked Nor was there any alteration of my pulse and I came back to the refectory really in doubt if I had been stung at all Next day there was no doubt I had grown in the night a fine goitre which woggled as I walked I shall not be so scared of wasp-stings in future, but my two-days' Derbyshire neck has made me very sympathetic towards the goitrous

* * *

There were about forty of us waiting in the Post Office but the formidable juvenile—she looked about thirteen—who was serving me suddenly recollected a grievance With pen arrested at the first syllable of my name she turned violently on her colleague on the right. "What did you do with that *good* pen I lent you on Saturday?" she demanded Her colleague was suave and soignee, she patted her perm "What pen was that, dear?" she asked smoothly, playing for time "That *good* pen," replied the juvenile bitterly, adding, to clear things up, "I lent it you on Saturday" "Oh that one," said the colleague, "I gave it you back" "Oh no, you didn't" "Yes, I did, dear You're using it now" A polite *fiction*· operations were still suspended on the top line "Not *this* one," said the juvenile with blistering disgust. "That *good* one The one I lent you on Saturday" "Oh *that* one," responded the colleague lightly "*That* was no good That's been put out for the public"

* * *

Schizophrenics are strange people I was turning over some old case-notes the other day and came on the story told me by a little cockney schizophrenic He and his family had built up a big business in, I think, canned food packing and distribution, and when the war came, they were doing very well indeed canning vegetables for the BEF I first saw him about Munich time, when they'd got their first big contract He was very very hallucinated, and so I never knew whether this particular story had a basis in fact or not Anyhow, he told me he had a car which he just couldn't sell He could afford a new one comfortably, but his business hadn't been built up by keeping old stock So he fixed up a little plan with a friend He went to work as usual, and parked his car in a side-street A quarter of an hour later, the friend arrived with a duplicate starting key The friend drove the car down to Dover, picked an isolated spot, set the car going, jumped out, and over the cliffs it went At one o'clock, the schizophrenic went round to the side-street to collect the car, found it had gone, rang up the police, and in due course collected the insurance money Just to make sure he got it, he used a broker who badly wanted to take on his firm's business The success of such an enterprise depends, as far as I can see, on one thing the existence of a really isolated spot on the Dover cliffs That's the part which makes me doubtful But the story as a whole isn't like a schizophrenic delusion It's too neat and clear-cut I don't know the answer, and I don't suppose I ever shall

Letters to the Editor

INGUINAL HERNIA

SIR,—After reading Squadron-Leader Arthur's article I would like to submit some points which have proved of value in my experience

1 It is unnecessary to fix the neck of the sac to the abdominal wall The complete removal of the sac allows the retraction of the neck well away from the internal abdominal ring To fix it to the abdominal wall, even some distance from the internal ring, fixes the parietal peritoneum where ordinarily it is singularly mobile from the parietes and I don't think we can improve on nature's arrangement in this respect

2 It is necessary to recognise, define and to suture transversalis fascia Several surgeons have mentioned this before It is not a stout structure in the inguinal region, but it is clearly there and does present an appreciable barrier when it is closed and the defect in it is likewise appreciable I believe, with others, that careful suturing of the fascia is as important, if not more so, than that of the muscle bellies in the reconstruction of a hernia It requires the finest silk or thread

3 Bassini's practice of excising cremaster muscle (a much larger structure than at first sight appears) with a view to reducing the size of the spermatic cord and therefore of the internal and external ring is valuable, but it adds 5 minutes to the operation

4 Careful mobilisation of deep Poupart externally and deeply also assists in the snug apposition of the above parts without tension

5 Bassini's procedure of inserting a key de tensioning suture of stout material through the lateral margin of rectus muscle and through the periosteum of the pubic spine is admirable Once this is tied, then conjoint tendon becomes relaxed and fits to deep Poupart easily This stout suture in addition brings the strongest portion of the posterior wall of *the inguinal canal behind the weakest portion of the anterior* inguinal canal (the external ring) and therefore it is sound surgically To affix conjoint tendon to deep Poupart, the finest thread or silk is adequate, being non irritant they do not provoke the inflammatory or sterile suppurative reaction characteristic of stout catgut, and besides they are unabsorbable The line of their insertion into deep Poupart's ligament is varied so that the strain is not on the same band of fibres, thus discouraging any tendency for them to split I think it was Admiral Wakeley who pointed out the advantage of this

6 With regard to the fascial graft, Wilkie used to suture the lateral edges together so that the graft was converted from a suture into a sheet and when this is possible it is worth doing Again, fine silk or thread in ophthalmic needles is used

7 External oblique can often, with advantage, be overlapped *It is often attenuated* and this strengthens the *anterior* wall

8 Bassini's method of regulating the size of the external ring by closing it with a series of interrupted sutures until it will just admit the tip of the little finger is a precise one It requires that the upper and lower pillars of the ring to the pubic spine be carefully cleansed beforehand, so that aponeurosis and not gubbins is sutured

Last, the repair of herniæ done with this attention to detail is somewhat time-consuming, taking from 30 to 40 minutes rather than the conventional 15 to 20, but it is well worth while because recurrences are hardly ever seen, even when this type of operation is performed on herniæ which have recurred three and four times previously

Harley Street, W HAROLD DODD

PROGNOSIS AFTER PERFORATION

SIR,—In your annotation of Oct 24 on prognosis after perforation you refer to the view sometimes held that such cases, subsequent to operation, have a better prognosis than others This was not confirmed, from the point of view of working capacity, in the observations of Scott and myself on a series of 430 cases of gastric and duodenal ulcer followed for not less than 3 and up to 20 years (*Lancet*, 1935, ii, 710) In 24 cases of perforated duodenal ulcer the subsequent average annual sick absence was 16 1 days for digestive disorders and 29 3

In England Now

A Running Commentary by Peripatetic Correspondents

To what limit of vituperation may honest indignation extend ? Though my father early impressed on me that common swearing merely showed inadequate knowledge of the richness of English, I am tempted to resort to expressions usually attributed to bargees and Billingsgate I cannot vie with Sterne's magnificent curse in *Tristram Shandy*, nor hope to approximate to the categorical minutiæ of François Rabelais, so as my father's teaching is still with me, I can only borrow a device from Leigh Hunt's *Reply to X* and say —— Were I to apply to A and B and C the terms improvident waster, callous dullard, losel, moron, defeatist, it would only be to demean still further these, the meanest words in the English tongue This ebullience is fired by the sight of waste by the few when the many are sparing no effort in salvage, in conserving fuel and water, in saving food and in sparing transport Some one said we shall win the war when every bus traveller puts every bus ticket in the box on the platform, for that will show that everyone has realised that no contribution to the war effort is too small to matter For myself, I think the truth was in him Unfortunately we have professional brethren who fail to exercise today's necessary care in prescribing and using drugs and the materials of our craft—however enthusiastic they may be over paper salvage and the like Fortunately they are few, but they still stick out like the proverbial sore thumb, and not only exasperate the rest of us who are doing all we can to relieve the acute drug shortages, but penalise patients throughout the country by their imprudent prodigality There are those who will *not* use the National War Formulary and cling to the obsolete National Formulary, thus not only wasting drugs, but man-power also, for pharmacists and NHI officials are put to much needless work by this obstinate refusal to cooperate There are the reckless prescribers who order a couple of ounces of ointment when half an ounce would suffice, or who meet minor maladies with " a couple of aspirins " when one would be adequate (if, indeed, it is the best drug to exhibit) This, mark you, despite the great shortage of ointment bases and the demand on phenol for war needs, but perhaps they do not know that aspirin is made from *phenol* Another example is morphine, one hears that the stocks held are fair, but they will not bear squandering, gr $\frac{1}{6}$ or gr $\frac{1}{8}$ will deal with most cases so why use gr $\frac{1}{3}$ or gr $\frac{1}{4}$? Alcohol and glycerin are scarce and needed for a host of purposes connected with war, yet there are those few who blithely prescribe preparations containing large amounts, just as they did in peace If the iniquity is pointed out they claim that nothing else will do for this patient, which demands a rude answer—the ruder the better—in ninety-nine cases in a hundred Well-informed rumour has it that the immediate result of the liquid paraffin order was a great increase of NHI *prescriptions for this substance both in number and in* the amounts ordered This could only mean that selfish interest dictated attempts to circumvent the order Then there are the proprietary addicts It is perhaps easier to write "℞ A & Co's Elixir elegans," than to prescribe a mixture designed specifically for the patient's needs, but it is less economical from every point of view

Having thus boiled over I may revert to a state of simmering, and repeat that it is fortunate there are so few doctors to whom these criticisms apply But there ought to be none, lukewarm efforts have no place in the nation's life today, and those who are not entirely with us are against us The magnificence of Russia's determination and sacrifice, the suffering of our allies and friends in occupied countries, demands that we do not scamp our part even in the smallest detail

* * *

Sir StClair Thomson's address to Edinburgh students on a house-surgeon's memories of Lister is a tribute from one who was his clerk, dresser and house-surgeon during the time when in London he was little better than a professional outcast He recalls how another surgeon (a president of the Royal College of Surgeons and Fellow of the Royal Society) often raised an appreciative laugh by telling anyone who came late into his r theatre to shut the door quickly for fear that one Lister's microbes might slip in, how he was ob by the sisters, and how, ten years after his arrival London, he was referring to the smallness of his cl as " a humiliating experience " Yet when his theatre was almost forsaken by students it was with foreigners Why was the prophet so long without honour in his own country ? That Lister changed gical wards from stinking death pits to something like what they are now, turned surgery from a rearguard action to a splendid victory, that he lit with the causal torch the dark and dangerous places of midwifery and of groping medicine—these are truisms today and were being glimpsed by many outsiders then, but those in closest contact with him were blind to it all Jealousy, of course jealousy in high places which set the style, jealousy which varies inversely with the square of the distance, feeds on hurried sight and sound, increases with age and therefore resents innovation, a late sexual sublimation, perhaps, which may have been valuable at times in checking spurious leaders, in testing, toughening and developing leadership, jealousy the spur, blinding jealousy which (see your postwar autobiographies) attacks the most able, jealousy which in this case cost hundreds of lives

Then there was another thing against Lister—he was impeccable If a man is a known sinner his rivals can more safely admit his genius A doctor who is a drunkard is allowed to be clever If you are doubtful about this try the effect on your own brain of reading a biography written in our own day, say one of Lytton Strachey's, or that excellent couple " Grey Wolf " and " Grey Steel," which show up their subjects in no indulgent light, and see if you don't finish up with an admiration, almost a love, for Kemal or Gordon or Manning Then read one of the old Victorian eulogies and if you can believe it's the whole truth you will almost loathe the fellow Of all Lister's great qualities two mattered his mental acuity, that gleam of gold that perceived the parallel between the even greater Pasteur's discoveries and wound suppuration, and the tenacity that held him to this view Had Lister been an evil liver and yet had these two, posterity's gratitude would have been the same and might have come sooner

Today the world is in some such morass as the surgical world was before Lister came, and we are threatened with many prophets. How shall we know those of truth ? And here one must profoundly disagree with Beethoven, quoted in this address, " where there is no great character there is no great man " If words have their usual meaning this is manifestly absurd, some of the world's greatest men have had most contemptible sides to their characters The greatest practical philosopher, whose thought touches every one of us every day (for example, he was doing an early experiment on food refrigeration when he died) was the sycophantic, corrupt —and what's more, caught-out—Lord Chancellor, Francis Bacon No, our prophet may not come stainless though I think we would do well to reject the more or less death-bed conversions of ancient sinners His message ? It will consist of certain primaries that are emerging from the ferment of men's minds even now that the old economy that burnt food in one part of the world while people starved in another, that sanctioned unemployment with its *triple death of labour, skill, and* soul must itself die, that possession of the relatively empty Y-chromosome does not give men any superiority over women with her two full Xs (O ye proud medical schools) and because a man inherits half his father's genes haphazard that should not entitle him to privilege or to be a legislator, that no-one is entitled to superfluity while others want, and so on and so forth Our prophet will declaim such things with an air of great originality and probably some peculiar emotional twist of his own, and everybody who has been groping towards these approximations to the rational will say, " How wonderful he is ! " All except those who are near him or of his own trade, and they will be intensely jealous and try and pull him down, giving the noblest reasons, but if he has been through hell before, this will merely spur our prophet on Lister's temporary misfortune was that he had not been through hell and that even with a gloriously demonstrable creed his work was the only assailable part of him If

Examination —She was thin, wasted, dehydrated and lrowsy Temperature 97° F , pulse rate 60, respirations 20 She vas just able to complain of headache There was no airiunger Tongue moist Chest and heart normal Bloodressure 100/65 mm Hg Abdomen n a d Scattered petechial ash over limbs, trunk spared Well marked neck rigidity Fundi could not be seen Pupils equal, reacted Turbid CSF, pressure 230 mm On film, pus cells +++, meningo cocci +++, the latter confirmed by culture Urine no albumin Benedict's test, bright red Gerhardt's and Rothera's tests strongly positive Blood sugar 234 mg %

Treatment —6 g of sulphapyridine were given intramuscularly immediately, and a further 6 g by mouth during the first twelve hours A total of approximately 40 g were given in the next seven days, and 20 g of glucose and 12 units of soluble insulin were given four hourly for three days Next day she was much improved, two days later pulse and temperature were normal, the rash had disappeared and there was no complaint of headache Recovery was uneventful, with no residual focal neurological signs On Feb 24 the sugar-tolerance test was fasting 212 (50 g glucose), 260, 388 She was stabilised on 150 g carbohydrate and 28 units of zinc protamine insulin

The complaint of headache and the purpura at once suggested the possibility of meningitis, which was soon confirmed by the neck rigidity and lumbar puncture Contemplation of Cole's cases and mine suggests that lumbar puncture should be performed on all diabetics in coma where the history and clinical signs are in the least unusual for diabetic coma This policy will prevent meningitis being overlooked and will lead to the prompt diagnosis of intracranial hæmorrhage to which diabetics are liable

The marked influence of meningitis in increasing the severity of diabetes is obvious in Cole's case 1 , in my case the effect on the diabetes appears slight The ages of these two patients and the severity of the diabetes may explain the difference Cases 3 and 4 are clearly not diabetics Case 3 is not recorded as having received any insulin, while case 4 had 210 units in ten days This quantity of insulin would not have been sufficient to treat a case of diabetic coma The same conclusion may also be drawn from the results of the sugar-tolerance tests Glycosuria and ketonuria are not infrequent in acute intracranial conditions and also, in my experience, in pneumonia There may be some temporary disturbance of carbohydrate metabolism, but insulin treatment is not required unless the clinical picture of diabetes develops

The association between these two common conditions is suspiciously rare It is to be hoped that Dr Cole's excellent account may lead to more frequent recognition of the association of two diseases which are today so amenable to treatment even when occurring together

Ipswich RONALD JONES

ANÆMIA IN PREGNANCY

SIR,—Dr Mole's assumption that the two groups of women, the effect of iron on whose hæmoglobin levels during pregnancy we published in the *Lancet* on Aug 15, are statistically of different " populations " is permissible since the difference between their means falls outside three times its standard error (1 04) The standard errors of the mean of each group initially is approximately 0 7 This difference, however, has no effect upon the conclusion drawn—viz , that iron administration has a beneficial effect upon the hæmoglobin levels in the later part of pregnancy

From the higher hæmoglobin levels of the untreated cases at the start it seems safe to assume that the iron reserves of these women were, if anything, somewhat greater than those of the women who later received iron, but despite this initial advantage their mean hæmoglobin levels fell by 9%, while those of the treated group rose by 2% Even though these two groups may have been derived from statistically separate populations, each group is homogeneous within itself, and the probability that the terminal figures are significantly different from the initial ones is over 20 to 1 for the treated group and many millions to one for the untreated

If those cases in the untreated group with initial hæmoglobin values over 90% be excluded, thus reducing the number in this group from 196 to 155, the inferences to be drawn from the results remain the same The two groups then have initial means of 76 and 75%, a difference which is statistically insignificant, yet the terminal averages for the two groups remain at 70% for the untreated and 77% for the treated Thus Dr Mole's criticism that the heterogeneity of the population invalidates the conclusions that we drew seems to be unjustified Actually the fact that the women in the untreated group had a somewhat higher hæmoglobin level initially, and yet fell so much more severely at the end, seems to strengthen rather than to detract from the argument we advanced for the administration of iron

Finally, so far as the planning of the experiment was concerned, it should be pointed out that at the time of examination of the patient's hæmoglobin the person carrying out the determination had no knowledge of the results of the previous investigations Further, the patient was or was not given iron according to the day, Tuesday or Wednesday, of her first examination, and was quite at liberty to, and often did, change her day of subsequent visits to the hospital, so that her presence on any particular day would provide no clue as to which group she belonged to, and thus lead to any bias on the part of the investigator, however unconscious

We feel that Dr Mole should have taken the trouble to assure himself more fully concerning the planning of *the experiment before making criticisms for which there* is no foundation

H A HAMILTON
Farnborough, Kent HELEN P WRIGHT.

STERILISATION OF SULPHONAMIDES

SIR,—The technique for the sterilisation of sulphonamides described by Major McCartney and Dr Cruickshank depends for success on the presence of a small quantity of moisture in the powder which may in some circumstances be absent At this hospital we have examined several samples of sulphonamide powders and have not yet found one to be sterile on receipt from the manufacturers The need for a completely effective method of sterilisation is therefore obvious Our work here is not yet complete but we have found that sulphapyridine and sulphathiazole can probably be sterilised effectively by dry heat at 150° C without either decomposition or aggregation of the powder into lumps Samples of sulphanilamide, however, have varied greatly in their behaviour towards heat, both as regards decomposition and aggregation , and an attempt is now being made to investigate the water content and try to correlate this with the effect of heat on the sample It seems possible that differences in moisture content may account for the varying results obtained by different workers and for the difficulty sometimes experienced in carrying out published methods for the sterilisation of these powders

Salford Royal Hospital JOHN B. LLOYD.

ANOTHER REASON FOR NOT SNEEZING

SIR,—Until four years ago I was afflicted at least three times a year by the common cold, of the type that did not leave me for three or more weeks So distressing was the catarrh and the general unpleasantness that I tried all the advertised cures, but still I suffered I reflected that in my own case a cold invariably announced its arrival by one, two or more sneezes A sneeze might not be followed by a cold, but a cold was invariably preceded by a sneeze So I adopted the empirical procedure of not sneezing I prevented a sneeze by grasping my nose firmly between my fingers or pressing my upper lip in the centre, or by sneezing into my belly, but whatever means were adopted I did not sneeze *through* my nose In the four years which have passed I have travelled fairly widely, and my duties have brought me into almost daily contact with colds , yet, in four years, I have not had a cold ! Is there one other person who will conscientiously try this preventive cure ?

George, C P South Africa THEODORE JAMES

PALSY AND INTRAMUSCULAR SULPHONAMIDE

SIR,—May I add a further case to the list of nerve palsies following intramuscular injection of sulphapyridine ? This occurred in a man suffering from appendicitis with peritonitis who, after operation, was being treated with soluble sulphapyridine injections given into the outer side of the thigh One morning, following days for illness of all sorts, as compared with 12 6 days for digestive disorders and 25 days for illness of all sorts in 216 cases where perforation had not taken place In 41 cases of perforated gastric ulcer the subsequent average annual sick absence was 14 8 days for digestive disorders and 23 8 days for illness of all sorts, as compared with 13 9 days for digestive disorders and 25 2 days for illness of all sorts in 149 cases where perforation had not taken place

London E C 1 H H BASHFORD

CÆSAREAN SECTION AND THE CRUSH SYNDROME

SIR,—Two of the annotations in the *Lancet* of Oct 10 were juxtaposed as though a link between them had been sensed—the volume of the blood In the woman at term the blood volume is increased, tending to conserve her from shock during cæsarean section under spinal anæsthesia in the crush syndrome, although the kidneys are affected by changes induced during the burial, serious renal failure seems precipitated only by transfusion and the giving of fluids to combat shock The two types of case are brought closer together by the occasional occurrence, in women previously apparently well, of renal failure after childbirth (postpartum suppression of urine) In this the blood, in virtue of its volume, not always sufficiently reduced by the birth loss, is operative It acts in concert with the effect of labour on the kidneys Free drinking, the pressing of fluids immediately after labour, enhances its force The cases are comparable with the anuria induced by emptying too suddenly the urinary bladder over-distended in men with enlarged prostate, always preceded by much distress and straining Conversely, the common absence of renal impairment in women with large ovarian cysts, the abdomen in size simulating that of late pregnancy, but the activity—the manner of living—in many cases being totally different, is associated with a volume of the blood subnormal for the weight of the patient That a too large blood-volume is pathogenic, qua renal failure, in the cases mentioned, is indicated by experiment—therapeutic procedure That in many cases of large ovarian cyst the blood-volume is reduced—is less than in normal non-pregnant women of the same weight—is postulated by argument Let us not forget that man is a high-pressure machine, and that the blood (in the aorta and renal capillaries) and the urine (in uriniferous tubules) are incompressible

I should like to dispel the fears of those timid at performing cæsarean section under spinal anæsthesia lest shock should appear I have performed the operation something more than 120 times, most of my cases—all for many years—have been done under spinal anæsthesia The needle is passed with the patient on her side, lying on the operating table. The space between the third and fourth lumbar vertebræ is best I pass the needle obliquely, the interspinous ligament being avoided, usually it goes in at once—the procedure seems more easy in the pregnant than in the non-pregnant After allowing about a drachm of cerebrospinal fluid to escape, 1 8 or 1 9 c cm of a 5% solution of tropacocaine (now unprocurable) is injected, 4 minutes by the watch, a nurse counting aloud the quarter minutes, being taken to make the injection The uterus is emptied with the patient flat, shortly after, the table is raised into the Trendelenburg position Since 1929, I have always performed the lower segment operation, the incision through the uterine wall has been invariably transverse I have not yet cut the uterine vessels, but often bleeding has been free for large veins medianly occur When labour has begun, the operation under spinal may be almost bloodless In one case, I found I had incised the vagina transversely, after extraction of the child the fringe of the cervix was seen above the incision I have never attempted to remove a large ovarian cyst under spinal with the patient flat because of the low blood-volume and fear of shock In my experience, in the pregnant woman, shock does not occur in these cases

I have had one cæsarean death under spinal, directly due to the tropacocaine, it was caused by neglecting the precautions mentioned and happened long ago In not one of my other cases has shock appeared, although at the operation no ephedrine or other drug has been given, and afterwards the patient has been starved for 24 hours the fluid intake greatly restricted, the patient allowed to drink freely only after the emission of urine in plenty Only in a very few of all the spinal anæsthesias I have induced—about a 1000—have I seen any sign of postanæsthetic complication—headache, eye-troubles—and these have been evanescent Cæsarean patients, as indeed all the others subjected to spinal anæsthesia, on return to the ward have been kept in the Trendelenburg position for 6 hours, the feet of the bed at the lower end being placed on chairs I remember one stillbirth in a breech case—I think I broke the child's neck by over extension during extraction, a colleague said it was otherwise I once performed cæsarean section in a case in which it was pretty certain that the child was dead, as the event proved, it was performed deliberately The pregnant woman being more susceptible to the effects of tropacocaine, exactitude of dose—even 0 1 c cm makes a difference—is highly important In all my cases the drug has been by itself effective, to the extent indeed that usually an anæsthetist has not been invited to attend No morphia is given before

So impressed have I been with the beneficent effects of spinal anæsthesia in patients on whom I have performed cæsarean section—the child crying at once, bleeding from the emptied uterus being eliminated—that for many years I have used spinal anæsthesia in ordinary midwifery cases, especially for first babies After the injection, the patient is placed in the lithotomy position, athwart the bed Forceps must be used, episiotomy is performed As with the cæsarean cases, the child cries at once, if the placenta causes trouble it is removed manually, otherwise postpartum hæmorrhage does not occur, the perineal wound is sewn up at leisure The bed is raised into the Trendelenburg position before the patient's legs are brought down, chlorine douches before and after are used, no complication ensues when asepsis is assured I have performed the operation in patients' own homes, in a breech case the effect of spinal was wonderful

Spinal anæsthesia has a further and a far-reaching advantage it cuts out all activity of the levator ani muscle during extraction In normal cases, and especially in well-developed primigravidæ, contraction of the muscle is the great obstruction to birth Paralysed by the drug, the muscle becomes flaccid, and its injury—the incising of it from its anterior (pubic) attachment by the passing occiput—so common in midwifery, whether forceps are used or not, but rarely observed at the time is prevented or much limited The result of using spinal is that subsequently, with the resumption of ordinary activities, the muscle is able to function as efficiently as before, preventing visceral extrusion, the so-called prolapse of pelvic viscera, a major misfortune

I miss any reference in your annotations to the use of the Trendelenburg position, both in the dogs subjected to crushing of a limb and in patients submitted to cæsarean section under spinal anæsthesia When will the position of the patient be recognised as of the greatest importance in the prevention of shock? When will a too great blood-volume be regarded as a cause of renal turgescence, and damming of the urine in uriniferous tubules and of the renal blood flow with a necessarily resulting oliguria?

Rugby R H PARAMORE

COMA IN CEREBROSPINAL FEVER WITH DIABETES

SIR,—Dr Leslie Cole has done good service in drawing attention (Oct 10, p 421) to the problems of diagnosis and treatment of patients in coma caused by meningococcal meningitis and diabetes A case recently under my care illustrates the diagnostic difficulty and shows that very severe meningitis may not exacerbate the previous diabetes

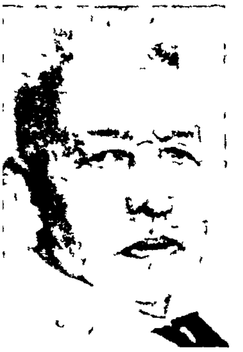
On Jan 26, 1941, I was called in consultation to see a woman of 54 alleged to be in diabetic coma On Jan 24 she had complained of severe headache and vomiting Next day a purpuric rash had developed on the limbs and there were complaints of limb pains, more vomiting occurred She had been under treatment since November, 1935, for diabetes mellitus and had been taking 10 units of zinc protamine insulin once daily and no fixed diet

Obituary

LUDWIG ASCHOFF

"He brought order and clarity into the description of morbid processes"—A Hoche

The death at the age of 76 of Karl Albert Ludwig Aschoff, for thirty years professor of pathological anatomy at the University of Freiburg, will seem almost unbelievable to those who knew him, for it seemed that such a vital man could never die. Throughout the medical world he is renowned for his original researches in many fields of pathology—appendicitis, arteriosclerosis, rheumatic carditis, gall-bladder disease, bile formation, cholesterol metabolism, thrombosis, gastric ulceration, thyroid disease and the concept of the reticulo-endothelial system. His work on rheumatism was first published in this country (*Brit med J* 1906), and his other important contributions were collected in *Lectures on Pathology* (1924), based on the Lane and Janeway lectures which he delivered in America that year. His *Textbook of Pathology*, of which an English translation was at one time projected is an invaluable work of reference as is his *Principles of Pathological History*, which was translated in 1902.



J F Lehmann

Life at the Institute at Freiburg under Aschoff was an experience. The brilliant lectures, the early morning review of current literature which ranged from holiday postcards and announcements of marriage of old pupils to the latest medical and general scientific literature, the two long laboratories—the Nordsaal, where the German assistants worked and as their song went "Schneiden und Färben und bis zum Sterben halten sie die Treue ihrem Institut," and the Südsaal which accommodated the foreign voluntary assistants, usually a strange medley of maybe an Englishman, one or two Americans, several Japanese, a Spaniard, and a Greek or a Dutchman. At four o'clock there would be coffee, or on special days tea—Aschoff always told how he adopted the English habit when he was at the Tropical Diseases Hospital in London in the early part of the century. Perhaps the chief would tell one of his famous stories, how he tried to pull a rickshaw, or of the Black Sea Kapitänin whose efficiency was tested by the sphygmomanometer. Occasionally there would be an evening party at Briems or the Falken and he would be joining in the singing, and if it promised to be a long night postpone the morning meeting an hour or even arrange for us to meet at 11 A.M. in the Alte Burse to drink Kalte Ente. He would join the ausflugs to little inns in the Schwarzwald and invited his students to his home "Ze Eschenhof," perhaps to share the Christmas pudding sent each year from England, to meet his charming wife who often sent a typescript copy of his letters as his miraculous microscopic handwriting might be difficult to decipher for poor German scholars, perhaps to see Jürgen his medical student son, or go down to the basement where his daughter did the most beautiful bookbinding.

Aschoff was great in everything save physical stature; he was a living example of all that was best in the old cultured Germany—often, if a specimen had been carelessly cut or crudely dissected, he would shake it saying "Das ist bosche"—and a devout member of the Evangelical Church. He staunchly upheld old university traditions and almost invariably wore a Zipfel of the Burschenschaft-Alemannia of Bonn while the Schmisse from his days as Aktivitas were clearly to be seen. His heart was heavy at the departure of his friends and colleagues in the medical faculty at Freiburg—Tannhäuser to Boston, Möllendorff to Zurich. But he was fearless in expressing his views, and his farewell address to his students and friends in 1936 was entitled Academic Honour, Academic Freedom, Academic Science.

Even after his retirement he continued to work, but he turned his attention more and more to the history of medicine and was appointed director of a newly founded institute. It was an old love, for in 1920 he had published a comparative table illustrating the social and historical evolution of medicine and his last book was the brilliant pathological section of the protoplasma monograph *Hundert Jahre Zellforschung* (1938). Aschoff's last visit to this country was in June of that year, when he delivered the Finlayson lecture in Glasgow on the history of the circulation. It had been hoped to have a meeting of his old pupils, but his asthma, an ever-present torment, forced him to hurry home to the pure air of the Schwarzwald, scattering notes of regret such as one that he was sorry he could not again visit Oxford and drink Magdalen Audit and enjoy himself.

A. H. T. R-S.

GENERAL PRACTICE OF YESTERDAY, TODAY AND TOMORROW

ERIC GARDNER, M.B. CAMB.

Looking back over a good many years of general practice I remember diagnoses and methods of treatment which enjoyed a fashion and then died out. When I was a student operations to immobilise a floating kidney became so general that in my final examination in surgery, the viva was entirely taken up by a discussion of the signs and symptoms of the condition and the surgical procedures for their relief. The mere diagnosis of floating kidney made to a susceptible person was enough to originate a train of neurasthenic symptoms. Such patients, fearing operation, flocked to physicians, and for months and even years slept with the foot of their beds raised, spent hours each day lying head downwards on an inclined plane, and never assumed a vertical position without first adjusting a kidney pad and a carefully laced corset.

Shortly before the 1914–18 war we began to hear a good deal about intestinal stasis as a cause of auto-intoxication. For years treatment was directed to the colon, some authorities even striving to obtain an evacuation after every meal. Bulgarian sour milk was prescribed, in the hope that the harmless "Bulgarian bacillus" would outgrow other more dangerous members of the intestinal flora. It enjoyed remarkable popularity, for it was unpalatable stuff, never very easy to prepare and few people used it properly; indeed a report on the constitution of the various preparations for souring milk showed that hardly any of them contained the bacillus.

Dietaries were compiled, some even imposing a fast once or twice a week; others gave full scope to the personal prejudices of their authors. Surgeons began to operate on the colon; it was freed from adhesions, straightened, short-circuited, and lesser and greater lengths of it were removed even to total excision. We were taught that stasis was due to the formation of loops and adhesions, and particularly to kinking at the hepatic and splenic flexures from enteroptosis, so that abdominal belts were again prescribed. An abdominal support, sold in thousands, consisted of a steel plate worn just above the symphysis and kept in position by two springs passing round the pelvis. One patient owed his life to such an appliance, not because it cured his enteroptosis, but because this armour-plating saved him from the nose cap of a German shell. Treatment also included abdominal massage with or without artificial support, intestinal disinfectants such as cyllin and salol, vaccines (then on the crest of a wave of popularity) and liquid paraffin. The final attack on the colon was made by lavage, and establishments were opened whose sole treatment consisted in washing out the large bowel. For some years they did a large business, and it was interesting to go into one and note the rubber tubes hanging up, neatly ticketed with well-known names.

The use of liquid paraffin alone has survived, though it is not in such demand as it was when I lunched in Harley Street many years ago. Cigarettes had been lighted, and the butler went round the table with a salver on which were three groups of liqueur glasses. He pointed to each in turn, "Brandy, sir. Curaçao. Paraffin, sir." We may be thankful that the state envisaged by Leonard Williams in 1918 has not materialised. He wrote:

> Victory is now in sight. In the new Utopia where stasis will be regarded as a sin more sinister than sedition and surfeit more unseemly than schism, fasts will cease to be the farcical

injection, he complained of severe pain in the lower part of the leg and foot He was found to have an area of anæsthesia over the outer side of the lower third of the leg and over the dorsum of the foot, with complete foot-drop The calf and plantar muscles were not affected It appears that only the external popliteal bundle of the sciatic nerve was damaged The anæsthesia, and anterior tibial and peroneal paralysis, remained unchanged over several weeks, after which I left the hospital and lost sight of the patient In this case the patient was not at all displeased with the accident as he was a prisoner from the neighbouring gaol and had been serving a long term for recurrent housebreaking

Leigh, Lancs D. K SAMBROOK

SCLERODERMIFORM SARCOID

SIR,—In last week's issue (p 524) you coin or quote the term "sclerodermiform sarcoid" and state that "the term sarcoid is applied to a group of neoplasms of the skin or subcutaneous tissue, in appearance resembling connective tissue and of low malignancy" To this one feels tempted to say *tot verba tot errores* Sarcoids may occur in any tissue and in any organ, they are not neoplasms but granulomatous tissue, they do not resemble connective tissue but have the appearance of non-caseating tuberculous foci devoid of any stainable or culturable micro-organisms, and they are as little benign or malignant in the strict sense as any tuberculous, syphilitic or leprous lesion Finally the only link between scleroderma and sarcoid is our ignorance regarding the causation of either A subcutaneous distribution of sarcoids was first described by J Darier and G Roussy in 1904, at a time when only the cutaneous manifestations of the disease were known Subcutaneous sarcoidosis is still today sometimes called "sarcoid Darier-Roussy" As such subcutaneous sarcoids differ in no way from sarcoids of other tissues, it seems pointless to retain a special eponymous term for this particular manifestation of a systemic disease already burdened by a varying combination of eponyms (Besnier, Hutchinson, Boeck and/or Schaumann)

Lambeth Hospital HERBERT LEVY

PULMONARY EMBOLISM BY AMNIOTIC FLUID

SIR,—Attention has recently been drawn in the *Lancet* (Oct 24, p 490) and in the *British Medical Journal* to a paper on maternal pulmonary embolism by Steiner and Lushbaugh (*J Amer med Ass* 1941, **117**, 1245, 1340) which gave details of 8 cases of maternal death, 2 during labour and 6 immediately after, and of the conditions found at post-mortem examination It put forward convincing evidence that these deaths were due to pulmonary emboli in the smallest arteries, arterioles and capillaries, composed of meconium mucin, fatty material resembling vernix caseosa, and epithelial debris The macroscopic appearances in some showed no important abnormality, in none any lethal change The writers of the paper suggest that the predisposing factor in the cause of the condition is some laceration in the placenta or membranes permitting entry of liquor amnii to the maternal circulation and that death occurs not from mechanical obstruction, due to an overwhelming shower of foreign matter into the maternal circulation but is rather in the nature of an anaphylactoid shock, comparable, for instance, with what occurs on the transfusion of non-compatible blood In the cases reported by Steiner and Lushbaugh there was one undelivered primipara, aged 26, and she died in fifty-five *minutes after the first sign of collapse* A case of sudden maternal death during labour occurred recently in a primipara and could not be accounted for until Steiner and Lushbaugh's paper offered a probable explanation The case history is as follows

A healthy young primipara aged 20, after a normal pregnancy, fell into labour about 11 PM on April 8 A routine prenatal examination made by the district nurse that morning had found all well, with the child lying left occiput anterior, and in the evening the patient had been out to supper and had been "well and happy" Labour pains began after she went to bed and progressed normally She was sick in the middle of the night and the husband wanted to call the nurse then, but the patient said not yet She was quite cheerful between the pains The husband went out shortly after 6 AM and before doing so took up a cup of tea to his wife About 7 AM her sister went into her room and talked with her she seemed all right About 7 30 the sister again went in time the patient was lying with her head under the and she did not speak The nurse arrived about 8 15 found the patient dead When she was seen about 10 there was marked lividity of the face and the tongue was truded between the teeth, appearances suggesting death asphyxia There was nothing in the mouth or larynx there was no vomit on the bed Rigor mortis was beginning

A post-mortem examination was made at 5 PM was nothing in the mouth, throat or respiratory passages to obstruct respiration Careful search failed to detect the presence of a visible embolus in the pulmonary vessels The lungs were not œdematous The pericardial sac was full of clear fluid The heart was contracted and empty, the valves normal There was no engorgement of cerebral vessels The os uteri was fully dilated, the child's head well down in the pelvis, the membranes unruptured The uterus was not opened

Ludlow, Salop T HUNTER.

SPERM SURVIVAL

SIR,—In taking specimens for the investigation of sterility Tynen and Ranson favour a sheath which has been previously sterilised and Dr Simpson recommends masturbation in a room adjoining the examination room I found by experience that the sheath method of collection was unsatisfactory owing to the fact that spermatozoa although present in large numbers often showed no motility I concluded that the sheath contained some chemical which killed spermatozoa and subsequently read with great interest Mr Ranson's investigations (*Lancet*, 1937, i, 1400) which confirmed this assumption To get over this difficulty I have for many years instructed my patients to collect specimens by the following method They take to bed with them a sterile bottle with a wide neck and screw-top lid which they keep at body temperature by placing it under the bedclothes They then indulge in normal sexual intercourse with their partner, taking care to withdraw just before the crisis and ejaculate into the bottle This of course must be kept at body temperature until the examination, a good plan for doing this in transit is to keep the bottle in the trouser pocket By this method of collection I have often observed motility in a specimen 24 hours old

Wimpole Street, W1 A H HARKNESS

EFFECTIVE DOSAGE IN GONORRHŒA

QUICK cures of gonorrhœa have been reported in the German Army Morschhäuser[1] tried out various sulphonamides in different dosage, culminating in a two-day treatment with sulphathiazole at the rate of 10 tablets a day With this the relapse-rate in 731 cases was 5 4%, and he found that the administration of 4 tablets in the morning, 3 at midday and 3 in the evening had given as good results as any other method, the relapse-rate in 355 cases treated in this way being again 5 4% Heyn[2] had also tried various dosages of sulphonamide, ending with 5 series of 250 cases each treated with sulphathiazole His results in these series were

(*a*) Treated with 10, 8, 6 and 6 tablets on successive days, and intraurethral injections of albargin, 8% relapses

(*b*) The same without local treatment, 10% relapses

(*c*) Treated with 10, 8 and 6 tablets on successive days, and local treatment, 8% relapses

(*d*) The same without local treatment, 9% relapses

(*e*) Treated with 10 tablets the first day and 8 the next without local treatment, 10% relapses

Taggeselle[3] in a lecture to health officers mentioned that in 110 cases of gonorrhœa treated with three tablets of sulphathiazole three times a day on two successive dates the cure-rate was 88% It is understood that we now have a good supply of sulphathiazole in this country.

CHADWICK LECTURE —On Tuesday, Nov 10, at 2 30 PM at the London School of Hygiene, Keppel Street, W C 1, Miss Joyce Adburgham, LRIBA, will deliver a Chadwick lecture on land settlement—its sanitary and architectural aspects and after war possibilities

Notes and News

APPROVED NAMES FOR DRUGS

DURING the war the General Medical Council, on the recommendation of the British Pharmacopœia Commission, has issued lists of approved names for substances produced by British manufacturers, in some instances under licence granted by the Comptroller-General of Patents, Designs and Trade Marks The lists have appeared in these columns The intention has been to recognise non-proprietary names which could be used freely by manufacturers, and thus to avoid the difficulties which result from a multiplicity of names for the same substance The Pharmacopœia Commission have now formed an advisory committee on nomenclature to assist them in the selection of approved names Suggestions for suitable names will be invited from the manufacturers interested The commission have adopted the following principles as a guide in the selection of names

1 Names should preferably be free from any anatomical, physiological, pathological or therapeutic suggestion This applies only to chemicals Such suggestion cannot always be excluded in the naming of biological products

2 The accurate chemical name should be used if suitable, when it is unsuitable the attempt should first be made to form a name by the combination of significant syllables from the scientific chemical name, and to include an indication of the potent element or constituent of a compound

3 Names should preferably be of two, three or at most four syllables

4 Names should be distinctive in sound and spelling, and should not be liable to confusion with those already in use

5 Names which are difficult to pronounce or to remember should be avoided

6 The addition of a terminal capital letter or number should be avoided

7 Names used in the current United States Pharmacopœia, or adopted for the next revision, should be used either as principal titles or as synonyms

8 Names used in the *British Pharmaceutical Codex* or in *New and Non-Official Remedies* should receive preferential consideration

9 The following well recognised terminations should be used as far as possible

Termination	*Applied to*
-ine (Latin ina)	Alkaloids and organic bases
in (Latin inum)	Glycosides and neutral principles
-ol	Alcohols and phenols (OH group)
al	Aldehydes
-one	Ketones and other substances containing the CO group
barbitone or itone	Barbiturates
-cane or aine	Local anæsthetics

The commission hope that the approved names will be generally adopted, and will especially deprecate the introduction of new names for substances for which approved names have been published

---

University of Oxford

An additional examination in medicine, surgery, and midwifery for the BM, BCh degrees will be held at the end of March, 1943

University of London

Sir Girling Ball has been elected dean of the faculty of medicine for the period 1942–44 and Prof G B Jeffery, FRS, dean of the faculty of science

Economics of Tuberculosis

The National Association for the Prevention of Tuberculosis, together with the Committee for the Study of Social Medicine, have organised a piece of research from which it is hoped to discover when the basic income of the tuberculous household is sufficient to obtain an adequate diet in war time The committee, under the chairmanship of Dr G Lissant Cox, has prepared a questionnaire, which has been sent to some hundred tuberculosis officers and their health visitors throughout the country Facts will be collected from cases with positive sputum whose annual income is less than £250 The results are being analysed, and will be submitted before publication to Prof Major Greenwood. It is hoped that a preliminary report will be issued shortly

Royal College of Physicians of London

At a comitia of the college on Oct 29, with Sir Charles Wilson, the president, in the chair, Prof W G Barnard, Major General A G Biggam, Dr Geoffrey Evans, Sir William Fletcher Shaw and Sir John Stopford were elected councillors Dr A E Clark-Kennedy was re elected a representative on the committee of management of the Conjoint Board, and Sir Comyns Berkeley a representative on the council of the Central Midwives Board The president nominated Dr W E Hume as Harveian orator and Dr J W Brown as Bradshaw lecturer for 1943, and announced the appointment of Dr A H Gale as Milroy lecturer for 1944, the award of the Streatfeild scholarship to Miss Enid Sampson, the Jenks scholarship to A J Graham, late of Epsom College, and the Linacre scholarship to C R Cheadle, of King's School, Canterbury

The following were admitted to the membership

M G C Ashby, BM OXFD, N D Compston, MB CAMB, W H Hargreaves LRCP, major RAMC, E J C Kendall, MB CAMB, Laurence Nagley, MD LEEDS, J L Penistan, MB LOND, Ernest Petrie, MB LOND, lieutenant RAMC, J S Pippard, MB CAMB, R E Rewell MB LOND, J F Smith, MB CAMB, surgeon lieutenant RNVR L W Smith, MB CAMB, R B Thompson, MB DURH, Andrew Topping, MD ABERD

Licences to practise were conferred upon the following 274 candidates (246 men and 28 women) who have passed the final examination of the conjoint board and have complied with the bye laws of the college

Patricia R Adlington, J N Agate P L Allen Eric Asquith, E O Barnes, A G Barnsley H W A Baron, T I Bartlett, R W Bazeley Ruth A Bell, C P Bennett H H Bentall, Charles Ben Yallouz, G G B Blackman J J Bligh S O Boldy, P B Booth, R J Bower, R A Bradford, P W Brand, Karol Braun, A H W Brenan, R N Briggs, Ruth M Burt, P H Buxton, N A Campbell, A W Capon, R J D Carrick L S Castleden, Marjorie F Chaplin, D P Choyce, Ann B Clark M W L Clements Philip Coggin Brown, J A H Collyns, D J Conway E G Cook, J B Cook, Rosemary I Cook, J A L Cooper P F Cooper Prudence A Cooper, M G Corcos, J M G Costello, Elizabeth F Cullis C F A Cummins Joan M Daniel, Owen Daniel A S Davidson D P Davis Herbert Davis, W E Denbow, R J Dickson, L S P Divers C E P Downes J T. Diplomas in child health were granted jointly with the Royal College of Surgeons to the candidates named in our issue of Oct 17 (p 474), and in public health to

Gwendolen M Allen-Williams, Nora E R Archer, Hilda M Robertshaw, F S D Thompson and H G Topping fancies of a few faddists and become facts The function of the police will be the purveying of paraffin, pilgrimages will be made not to Palestine but to Plombières, and Higginson will be High Priest

* * *

Operations for the removal of the tonsils and the appendix are often cited as being performed too often, but assuming that reasonable care has been taken to reach a diagnosis it is surely safer to operate than to temporise We can all remember one or more deaths from fulminating appendicitis in people whose initial attack should have been a sufficient warning A chronically infected tonsil will continue to give trouble till it is removed, and its definition by the late Mr Herbert Tilley as a tonsil causing acute or chronic ill health still holds good There have been changes in methods of removing tonsils from the time when it was thought only necessary to snip off under gas as much of a redundant tonsil as would slip easily through the ring of a guillotine, to the careful dissection of today, but these—even including the temporary relapse into the use of the electric cautery—were real attempts to improve the technique of a tricky and sometimes difficult operation

At one time it was customary to circumcise nearly all male children as a matter of routine Now I think wiser counsels have prevailed, and if the foreskin is freed at birth and can be retracted, only ordinary subsequent cleanliness is considered necessary I have pointed out to parents who insisted on their children being circumcised, that because Moses in charge of a body of people in a desert subject to dust storms under tropical conditions, and with almost all the available water used for drinking, thought fit to order circumcision there was no reason why we should now continue it, when every council house has its own bathroom

Leeches are now difficult to procure, but nothing is more dramatic than the relief they afford to a patient suffering from acute pericarditis or pleurisy Expectorant mixtures are used less often, most of them have been shown to have no therapeutic value, but because they were usually prescribed at a stage in an illness when nature was performing the functions attributed to them, they gained a fictitious reputation We hear little today of tuberculin in the treatment of active tuberculosis though at one time it was widely used Vaccines have fallen out of fashion for many conditions once treated by them, and I seem to remember that we used to give children large quantities of glucose for acidosis

One is on more dangerous ground in discussing remedies of today, but I sometimes wonder how much of the present day convulsive therapy will stand the test of time, and whether in striving to make labour painless we are not helping the mother at the expense of the child Vitamins are essential constituents of our diet and after a quarter of a century their importance has not been questioned, but I doubt whether it is wise to supplement what we eat with as many vitamin preparations as we are urged to do by present day advertising I was shocked when I was medical officer to a school of 100 boys, to find one term that no less than 75 of them had brought back some form of vitamin preparation to supplement their diet, the school was fed entirely on home-killed meat and fresh vegetables grown on the estate

* * *

In the future there may be changes in the medical curriculum, but medical teaching must always rest on the solid foundation of anatomy, physiology and pathology Later the student will learn about clinical laboratory methods and such aids to diagnosis as radiology and cardiography, but they should never be allowed to usurp the place of clinical observation I would also plead for a greater insistence than is observed in some medical schools on attendance in the post-mortem room, especially at autopsies on people who have died from the common conditions the student meets daily, he will then be able to note the changes due to advancing years and how they handicap treatment

Soon there will be changes in the profession that will affect the practitioner to a degree he hardly yet realises He should consider this matter deeply and voice his opinion, or he may find he is a mere cog in a mechanised profession Rehabilitation centres are doing a great deal for our soldiers at the present time, it is inconceivable that they should be allowed to wane after the p for they can play a great part in the future of convalescent homes At a rehabilitation centr man comes to realise that even if he has broken string of his fiddle, he still has three left on which to a tune One of the most important changes needed i profession is machinery to enable the practitioner to in touch with modern opinion and modern practi diagnosis and treatment

Many practitioners are men of outstanding ability knowledge but there is a substratum to whom mo ideas filter slowly Most of these have a busy practi possibly too busy—and feel that any spare time is t for recreation rather than for reading They ha working knowledge of what they are likely to mee the course of a day's work, and sufficient ability to t it according to their standards, and they trust to th carry them through their difficulties A short time I met a man who had had the misfortune to lose a pat under an anæsthetic, from ether convulsions The drug that might have saved the boy was withheld in s of all that has appeared on this subject in the med journals in the last two years Then I have been surpr to find how many people who die from coronary ar disease have been treated by alkaline mixtures on assumption that their pain was due to some gas condition, and even with liniment for the "rheumatis in their left shoulder Most men feel they have no t to wade through a large textbook, but a well-cho modern book on such a subject as heart failure can fail to widen their ideas and add an interest to their w Some men obtain a nodding acquaintance with new dr from the brochures, often meritorious, of manufactu chemists, but drawbacks are associated with a knowle based on information sent out by the manufactu firms for the sole purpose of selling their goods other day I asked a doctor if he was using much sulp pyridine in his practice "Oh, yes," he said, pullin large tin of tablets out of his pocket and shaking it, give it to everybody who has a temperature If, improves I go on with it, but if nothing happens I s it Wonderful stuff Saves lots of time " Later in day I put the same question to another man "N he replied, "I have not used any of those drugs yet think they may be rather dangerous, and I don't wan death from agranulocytosis on my hands " Consider how valuable and how potent the sulphonamides a it is significant to note how casually they are someti prescribed or ignored

The main body of the medical profession is like a la army fighting with little or no contact with its he quarters Any drastic change requires much thoug for generally Englishmen work best individually C trol should be elastic, not hampered by the rigid rout imposed by an office clerk or by a multiplicity of for but free to adapt itself to special circumstances so tha will be supported by the full cooperation of those work under it

---

Infectious Disease in England and Wales

WEEK ENDED OCT 24

Notifications —The following cases of infectious dise were notified during the week *smallpox*, 0, scar fever, 2619, whooping-cough, 984, diphtheria, 97 paratyphoid, 7, typhoid, 12, measles (exclud rubella), 6803, pneumonia (primary or influenzal), 65 puerperal pyrexia, 162, cerebrospinal fever, 66, pol myelitis, 25, polio-encephalitis, 2, encephalitis leth gica, 2, dysentery, 177, ophthalmia neonatorum, No case of cholera, plague, or typhus fever was notifi during the week

Deaths —In 126 great towns there were no deat from enteric fever, 1 (0) from scarlet fever, 7 (0) fr measles, 6 (0) from whooping-cough, 21 (0) from dip theria, 48 (2) from diarrhœa and enteritis under t years, and 18 (1) from influenza The figures parentheses are those for London itself

Liverpool had 3 deaths from diphtheria Manchester reporte fatal cases of diarrhœa

The number of stillbirths notified during the week w 188 (corresponding to a rate of 31 per thousand tot births), including 17 in London

JUVENILE RHEUMATISM ITS PROBLEMS*

REGINALD MILLER, M D LOND, F R C P
SENIOR PHYSICIAN TO ST MARY'S HOSPITAL, PADDINGTON

THE whole clinical aspect of the rheumatic state in childhood and early life was for the first time brought into correct focus by W B Cheadle in his Harveian lectures for 1888, and with such accuracy that only comparatively minor readjustments have since been required Endocarditis, pericarditis, pleurisy, tonsillitis, exudative erythema, chorea and subcutaneous nodules were described as seven phases of the disease which, together with arthritis, formed the rheumatic series Cheadle expressed no personal views on causation After mentioning infection as a possible explanation of the rheumatism of childhood he was content vaguely to allude to " the rheumatic poison, or whatever the morbid influence may be," and in this he doubtless merely reflected the unsettled views of those days In 1900 these lectures, revised with the assistance of F J. Poynton, were republished The original text was reproduced almost without alteration but a description of rheumatic myocarditis, which by then had been studied by D B Lees and Poynton, was added and a more sympathetic allusion to the infective hypothesis of causation With the turn of the century the study of juvenile rheumatism became concerned particularly with bacteriology and carditis Its bacteriology was chiefly associated with the names of Poynton and A Paine, and the study of carditis with the name of C F Coombs The bacteriological problem seemed to be simple at the start but proved to be, and remains, complex and difficult With some modification in nomenclature the views of Poynton and Paine survived a deplorably fierce controversy in this country and made progress in the calmer atmosphere of America, but with the passage of time they have become once again a permissible subject for discussion here under the neutral formula of " the streptococcal hypothesis " Coombs in 1924 published the first monograph on rheumatic carditis In this he elaborated independently the work of Aschoff, and his results not only strongly supported an infective origin for the disease but showed that the histopathological changes—the tissue-reactions to the infecting agent—were peculiar to this disease

Juvenile rheumatism has thus come to be regarded as a generalised infection producing a definite clinical picture associated with special pathological features , and in spite of a lack of agreement on the exact type of infecting agent, this conception of the disease has been sufficiently widely accepted to form the basis of further research

The third and present phase of study is chiefly concerned with the disease as a problem in public health Such a development was overdue It seemed as though the bacteriological controversy had frightened workers in this country off the subject, and juvenile rheumatism had become accepted as unavoidable , but the appeals of Poynton and other enthusiasts for special help in dealing with rheumatic heart disease in children, and the beginning of preventive work in America, gradually prepared medical opinion here for organised efforts At the annual meeting of the British Medical Association in 1923, the medical section asked for a committee of investigation to consider rheumatic heart disease The first report of this committee, published in 1926, dealt with causation, the second report with prevention and control In 1927 the Medical Research Council published a report on social conditions and acute rheumatism, and in the same year the Ministry of Health reported on acute rheumatism in children in its relation to heart disease These may be taken as the starting-point of an organised effort to prevent and control juvenile rheumatism in this country

The term juvenile rheumatism came first into use when acute rheumatism in children under sixteen years of age was made a notifiable disease in Paddington on March 1, 1927

Clinical Problems

The clinical picture of juvenile rheumatism is now completely drawn, and will need little modification when the bacteriological problem has been finally solved I shall not describe here the manifestations of the disease, but will discuss their significance in the general scheme of the infection

Tonsillitis —That an attack of acute rheumatism was commonly ushered in by tonsillitis was well recognised by Cheadle who regarded the tonsillitis as a manifestation of the disease This is true but not the whole truth If the streptococcus associated with the production of acute rheumatism is to be regarded, as seems likely, as a normal inhabitant of the alimentary tract, what factor enables it to undertake a rôle of " parvenu pathogenicity " as Coombs called it [2] On the other hand, a tonsillitis which seemingly belongs to a different infective disease may also be followed by rheumatism the sequence of acute rheumatism after scarlet fever has long been recognised, and more recently attention has been called to the same effect of the tonsillitis of epidemic influenzal catarrhs in wards full of rheumatic children Yet we cannot regard rheumatism itself as a result of infection by streptococci commonly classed as hæmolytic, nor is the suggestion that the disease in children is ordinarily set up by case-to-case infection in agreement with clinical tradition A further point, discussed of late years, is the interval of time which often elapses between the initial sore-throat and the acute attack of rheumatism. The regularity of this " silent period," as Bernard Schlesinger has called it, has perhaps been overemphasised, but it is certainly common that in the development of juvenile rheumatism there is first a period of some months with recurring mild sore-throat and rheumatic symptoms, then an attack of acute tonsillitis, and finally, within 3–21 days, the full-blown acute rheumatic attack Whether this sequence indicates that allergy is important in the production of the acute phases of the disease has been much discussed

From the practical point of view, the throat seems to serve as the chief portal of entry for the infecting agent to the blood-stream The importance of acute or chronic tonsillar infection is therefore great, and it is noteworthy that in tonsillectomised children first or early attacks of rheumatism tend to be relatively mild, limited largely to chorea without carditis

Carditis —It is agreed that carditis is especially prone to develop in the rheumatism of childhood, following the rule that in children, more than in adults, infections tend to become generalised It is further agreed that the carditis of juvenile rheumatism is primarily responsible for the many deaths from heart disease in early middle age among the parents of young families—the peculiar tragedy of this disease But it is not always recognised that the incidence of carditis depends not only on the frequency but on the virulence of the infection Efforts to control juvenile rheumatism should not be criticised merely on the ground that they fail to prevent rheumatism the essence of the matter is whether the disease has been so modified that the incidence of cardiac lesions is relatively light It is on this point, for example, that the argument in favour of the removal of infected tonsils in rheumatic children is based

Chorea —Cheadle regarded rheumatism as by far the commonest cause of chorea, but hesitated to pronounce it an essential factor in the production of that disorder Later laborious statistical investigations showed that rheumatism could be recognised in such a large proportion of cases of chorea, before, during and after an attack, that the small margin left was no greater than could be accounted for by instances of rheumatic infection in which chorea existed as the sole manifestation Of late, however, some authorities in America have expressed the opinion that chorea by itself is not to be regarded as proof of rheumatic infection in a child The increase in the apparently non-rheumatic cases of chorea is possibly due to modified severity of the infection The high proportion of uncomplicated chorea in tonsillectomised children has already been mentioned , and it has always been agreed, as Coombs pointed out, that in some children chorea is produced by a smaller dose of rheumatic infection than any other manifestation of the disease To recede from the established pan-rheumatic view of chorea seems regrettable, since it brings a risk of possible misinterpretation of an early symptom of juvenile rheumatism

* The Lumleian lectures for 1942 not delivered owing to the war

University of Glasgow

On Oct 24 the following degrees were conferred

MB Ch B—Douglas Jamieson (with honours), N R Grist, Zoë M Mackie, L H Holroyd, Edith E Little, Mary S W McCallum and Jean A Gibson (with commendation), Jane E Allan, W M Allan, Andrew Anderson F A Ayles, J T Baird, Agnes D Barr, James Beattie, G A Bell, J C Beveridge, W H Black, T A S Boyd David Brash, Annie C Brown, J K Brown, W M Brown, A S Browne A H Bruce, J T S Buchan, R A Burnett, A A Clark, David Clark G L Clark, John Colquhoun, W M Connell, A H Cook, N R Cowan, Robert Dickie, Mary C Fee Margaret S Ferguson, R S Ferguson, W G Ferguson, O A Finn, C R Forrest, Arthur Foster O C Fowler, Andrew Fraser, Conrad Freed, Thomas Graham, T E Graham, Anne C Y Greig, Andrew Grierson, J M Hendry, R K Hinshalwood, Jean T Holland, Alexander Hughes, Thomas Jack, J R Kenyon, Mary M Kirkland Robert Lamb, Joan B Landsman, Lilian Links S K Livingston, D F McAlpine, Sarah Macaskill, A K McAuslan, J B McBean, J Dunlop McCardel H R F Macdonald J A Macfarlane, George McHugh, A B MacLean O D T MacLean, H I Maclean, J S McLintock John McMillan, Violet C I Macnab, Ian MacPhail, Joseph McSevich, W S Magowan, R G Main W G Manderson, Margaret H E Martyn, Marjory B Miller, J G Muir W J Murphy, Camming Naysmith A S Nicolson, C B Noble, Ellen O Hagan, Francis O'Reilly T M Paterson, Helen B Phillips, Marie H I Reid, A M Robertson E M Robertson, J A M Robertson Constance A O Ross J S Scobbie, J K Scott, G B Shaw, Nathan Shieff, R W Simpson John Smith, A M Stevenson, G T Stewart, M L Thomson, R M Thomson Andrew Tomney, E W N Trounson Barbara C Tulloch, A K Turnbull, R R Waddell, Alison C Wallace, J M Wallace, W S Wallace, R G Whitelaw, M M Whittet, A H L Wilson I R Wilson, W S Wilson, A P Wright, H B Young, I S Young and Stuart Young

Scottish Conjoint Board

At recent examinations of the board of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow the following were successful

LRCP & SE, LRFP & S

R W Adam J F Allan H A Anderson, A G Annan S W Bowden, W H N Calwell William Candib Yoanis N Caravannopoulos T A Christie, J F Couch, G L K Crampton, D V Curran G H Curtain, D B Donaldson, M A A El Gayar, D M Forsyth, Israel Gitlitz I G Graber Y H Karara Abraham Klar, Kathleen M McCusker Malcolm Macintyre, A F McInnes Amy Mooney, A S Neilson, O M Neshamkin D J M D Roper, A R G Salem W J H Sayers, A H M Shouman, J A Sinclair, B M Singh A W Smith, Benjamin Solomon, W J Stevenson, G H Vawda and Roderick Williams

Royal College of Surgeons of Edinburgh

At a meeting of the college on Oct 21 the following office bearers were elected for the coming year president, Mr. J W Struthers, vice president, Dr H M Traquair, secretary and treasurer, Mr K Paterson Brown, members of the president's council, Mr James Graham, Prof R W Johnstone, Sir John Fraser, Mr A Pirie Watson, Dr G Ewart Martin and Mr Francis E Jardine, representative on the General Medical Council, Mr Alex Miles, convener of museum committee, Mr W Quarry Wood, and librarian, Dr Douglas Guthrie

Paper Economy Committee

The Minister of Production has appointed a paper economy committee to help him to reduce the consumption of paper The committee will be concerned with the economic use of paper and not with the collection of waste paper, and will examine all cases of excessive use of paper and take steps to effect economy Further economy is essential, and the Minister is satisfied that it can be obtained He asks paper users to give the committee all the help in their power. The committee's address is 3, Central Buildings, Westminster, S W 1.

Medical Honours

The MBE has been awarded to Mr D O Clark, medical officer of a mobile unit in the civil defence casualty service at Weston super-Mare

The following awards have been made in recognition of gallant and distinguished services in Burma between last December and May.

CBE—Brigadier (T.) T. O Thompson, DM OXFD late RAMC.

OBE—Lieut Colonel Frank Oppenheimer, MB MANC, IMS.

DSO—Colonel (T) G E. MacAlevey, MC, MRCS, RAMC Captain C W. Elphick, MB DURH RAMC

MC—Captain Hugh O Hara, LRCPE RAMC

Medical Casualties

The following casualties have been announced

Missing presumed killed—Surgeon Lieut Commander Maurice Cay, MB EDIN, RN

Wounded—A/Lieut Colonel A W Gardner, MRCS, RAMC

Pharmaceutical Society of Great Britain

At Friends House, Euston Road, London, N W 1, on Thursday, Nov 12 at 2 30 PM, Prof J C Drummond, DSc, will address this society on nutrition.

Medical Insurance Agency

Sir Humphry Rolleston has resigned the chairmanship this agency which he has held since 1924 Sir R Hutchison has been appointed his successor

Royal Sanitary Institute

A sessional meeting of the institute will be held at mouth on Saturday, Nov 14, when Dr A G Shand will a paper on diphtheria immunisation with special reference the work of a mobile unit Dr J W Thornton will also speak on war time disinfestation Further information may be had from Dr A B Williamson, the hon. local secretary, Northern Secondary School, Mayfield Road, Portsmouth

Royal Society of Medicine

The section of psychiatry of this society will meet on Tuesday, Nov 10, at 2 30 PM to discuss neurosis in general practice during air raids The openers will be Dr J Whitby and Dr Russell Fraser At the same hour, at the section of therapeutics and pharmacology, Dr W F Young and Dr R A McCance will open a discussion on water metabolism in sick and healthy infants On Nov 13 at 2 30 PM at the section of ophthalmology Dr M Klein will read a paper on refraction and Mr A J B Goldsmith a paper on chiasmal arachnoiditis

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

---

Appointments

CLARKE, ELIZABETH M R, MB NUI, DPH, FDD asst MO for Northumberland

LOUGHNANE, F MACG, FRCS temp hon asst surgeon to the genito urinary department of the Prince of Wales's General Hospital, Tottenham

LANGLEY G F, CH M BRIST, FRCS hon asst surgeon to the East Suffolk and Ipswich Hospital

---

Births, Marriages and Deaths

BIRTHS

BURFIELD—On Oct. 18, at Musoma Tanganyika Territory, the wife of Dr. George Burfield, Colonial Medical Service—a daughter

BUTCHER—On Oct 24, at Lincoln, the wife of Dr H G H. Butcher—a son

COPLANS—On Oct 25 in London, the wife of Surgeon Lieutena Robert Coplans, RN—a son

FRAZER—On Oct 26, at Sutton, the wife of Surgeon Lieuten W Fitzgerald Frazer RNVR—a daughter

O'BRIEN—On Oct 25, in Dublin, the wife of Captain H D O'Brie RAMC—a daughter

OWEN—On Oct 24, at Eccleshall, Stafford, the wife of Dr Glynne Owen—a son

ROOKE—On Oct. 28 at Bournemouth, the wife of Lieutenant K. Rooke, RAMC—a daughter

WARING—On Oct 18, at Hitchin, the wife of Dr John Waring— daughter

WEDDERSPOON—On Oct 28 at Alverstoke the wife of Surge Lieutenant J M Wedderspoon, RNVR—a daughter

WILSON—On Oct 23, at Leicester, the wife of Mr William W Wilson, FRCSE—a daughter

MARRIAGES

ANDERSON—SINGLETON—On Oct 22, at Gillingham, Dorse Hugh Fraser Anderson, captain RAMC, to Nancy Singleto TANS

HATCH—JAMES—On Oct 24, at Peebles, Christopher Roger Hatc RAMC, to Berwyn Russell James, FANY

McKEAN—STONE—On Oct 24, at Ledbury, Carl William Fortesc McKean, MB to Lorna Mayo Stone

PARSONS—FLOOD—On Oct 28, at Oxford, Denis Shirley Parson BM, to Margaret Elizabeth Flood

RUTHERFORD—SANDERS—On Oct 23, at Newcastle on Tyn Robert James Rutherford, FRCSE, flight lieutenant RAFV to Elizabeth Howard Sanders, MB

VULLIAMY—GOULD—On Oct 31, at Sanderstead, Surrey, Dav Gibb Vulliamy, MB, to Daphne Isabel Gould

DEATHS

FAICHNIE—On Oct 30 at Bedford Gardens, London, W Frederic G Faichnie, MRCS, lieut-colonel RAMC, retd aged 72

FULLER GOOD—On Oct 27, James Fuller-Good MB, colonel IM retd.

LAMBERT—On Oct 27, at Lincoln, Frederick Samuel Lamber MRCS, lieut colonel RAMC (T), aged 78

LENNANE—On Oct 23, at Addiscombe, Alfred James Andre Lennane, MRCS, aged 78

MACKENZIE—On Oct 30, at Tiverton, Devon, Lewis Mackenzi FRCS, aged 93

MURRAY—On Oct 25, at Tunbridge Wells, Henry Walker Murra MB DUBL, retd colonel AMS, aged 88

SUMMERHAYES—On Oct 28, John Orlando Summerhayes DS MRCS, lieut colonel RAMC (T) retd, of Saxonholme, Newhave

Bacteriological Problems

In 1898 Poynton and Paine began to investigate the bacteriology of juvenile rheumatism In searching for the bacillus which Achalme in 1891 had claimed to be the causal agent of the disease, they found instead a minute diplococcus which grew artificially in chains and was apparently identical with one already being studied in the same connexion by Wassermann in Germany Poynton had been originally attracted to the study of juvenile rheumatism because of all the disorders then labelled as rheumatic this seemed to be the disease in its purest form ; and no doubt he expected its bacterial cause would be recognisable outside the body as proper to that disease in the language of those days a specific disease would be caused by a specific micro-organism In view of this it was natural that the peculiarities of the diplococcus (rather than its similarities to a streptococcus) should be emphasised, especially as it produced non-pyogenic lesions , and thus it became labelled *Micrococcus rheumaticus* Consequently when later bacteriologists reported that such an organism was not only hard to find but when found was in no way different from a *Streptococcus viridans*, its claims to be the causal agent of acute rheumatism were pronounced void

The first objection to it is, of course, fundamental , if the streptococcus is really found so seldom in connexion with acute rheumatism that it cannot be regarded as significant, then the cause of the disease remains unknown But after all these years it seems impossible to continue to adopt this attitude the same positive results have been obtained too often by too many investigators Streptococci have been obtained in cases of rheumatism during life and after death, and that they should even rarely be found in the cerebrospinal fluid in chorea, or in the interior of a subcutaneous node, is bound to impress the physician , and since the acute septicæmic phases are uncommon and transient, he is ready to regard one positive as outweighing many negative results It seems, therefore impossible to deny any association between acute rheumatism and streptococcal infection It follows that problems of identity, classification and specificity of the streptococcus are of subsidiary importance formidable as they are, they do not necessarily disprove the truth of the streptococcal hypothesis That the streptococcus of rheumatism cannot be morphologically distinguished from streptococci which are normally present in the alimentary tract presents no great difficulty The powerful influence of environment in predisposing to juvenile rheumatism, and the repeated relapses associated with fresh tonsillar infection, are in line with the possibility that the organism is a normal inhabitant of the body In spite of its clear-cut clinical features the disease does not suggest the fortuitous meeting of a child with some entirely foreign microbe A second difficulty is that the streptococcus isolated from a case of rheumatism cannot be distinguished from that obtained from endocarditis lenta, and that experimentally it will often set up endocarditis of the malignant type rather than of the simple rheumatic type This difficulty is not to be explained away on the basis of mistaken clinical diagnosis, but it may easily be within the capacity of the same micro-organism to set up either type of endocarditis Coombs held that the type of endocarditis depended not so much on the type of micro-organism as on the route by which the valve becomes infected "Possibly," he wrote in 1926, "the same streptococcus may excite at one time an acute rheumatic pancarditis, at another a slowly progressive endocarditis, invading the whole of the cardiac tissues by way of the coronary supply in the one, but attacking only the endocardial surface, which it has reached from the cardiac cavities, in the other " This contention, which serves well to bridge the difficulty, was the result of a long study of the histology of rheumatic carditis and of the embolic lesions of endocarditis lenta It deserves more consideration than it has received

The chief objection urged against the streptococcal hypothesis at present is concerned with the peculiar formative histological lesions found in rheumatism How do these conform to the idea of a streptococcal origin for the disease ? Coombs studied the histology of experimental rheumatism induced by the injection of streptococci grown from human rheumatism His conclusions, published in 1912, were to the effect that differences in the histological pictures in experimental and human rheumatism were not more than could be accounted for by the difference in the mode of production of the two conditions—the first being produced by a massive dose given all at once, and the second by a series of comparatively small doses He found that lesions of experimental rheumatism included "all the phenomena, even the submiliary nodule, found in the rheumatic lesions of man " In 1926 he briefly reaffirmed his belief In endocarditis lenta, Coombs found that, as in rheumatism, a reaction "predominantly formative" may be seen both in the infected valve and the embolic lesions of the disease He laid stress on this as contrary to the widespread impression that reactions to streptococcal infection must always be suppurative

Surveying the present position of the streptococcal hypothesis, the evidence that the streptococcus found in rheumatism is in causal connexion with the disease may be taken to be sufficient But this does not as yet provide us with a simple solution to what might be expected to be a simple problem some factor seems to be eluding us It has been suggested that a virus infection may be at work in association with the streptococcal infection, or indeed alone , but as yet the evidence in favour of any virus infection is far too meagre to be of weight, especially when the total lack of immunity conferred by rheumatic infection is borne in mind Again, a possible allergic factor has been much discussed, emphasis being laid on the silent period commonly observed between the initial tonsillitis and the acute systemic symptoms of rheumatism It is not easy to realise what part in the disease is claimed for allergy , it can hardly be regarded as predisposing to fresh invasions of the blood-stream, or as responsible for the pathological lesions of the disease But that is not to say that allergy plays no part in the production of rheumatic manifestations The allergic character of rheumatic erythema has been mentioned, but its peculiarities do not encourage the belief that allergy is an important factor in producing an acute attack of rheumatism On the other hand it still seems unlikely that a streptococcus which breeds so true in the medium of the human body should continue indefinitely to escape recognition by bacteriological methods, and it is to the perfection of these that we must look for the complete solution of the bacteriological problem Thus to accept the streptococcal hypothesis as true does not imply that it has yet been proved to express the whole truth, although there are not lacking signs that ultimately it will attain even to this position Three general considerations favour this hope . it has lived for over forty years (no inconsiderable life for even a scientific "fact") , not only is it without competitors but it has formed, and still forms, the basis of nearly all laboratory research on acute rheumatism , and the younger generation of physicians, unmindful of past controversies, accept without difficulty juvenile rheumatism as a streptococcal disease and allow this view to influence their treatment

Public-health Problems

In attempting to control widespread juvenile rheumatism in this country we have at least one important indication to follow up the class-incidence At the same time we must bear in mind the importance of tonsillar infection Can a relationship be established between this and the class-incidence of the disease ?

Class-incidence —Juvenile rheumatism is massed among the children of the poor and is limited to them to a peculiar degree—far more strictly than is, for instance, pulmonary tuberculosis However investigated, and it has been tested in various ways by many workers, this fact is always substantiated †, so that the social status of the child is a predisposing factor of predominant importance

The upper limit of the rheumatic stratum in children seems to coincide with, or to be slightly above, the social status of those attending the elementary day-schools , its lower limit is much more indefinite J Alison Glover has claimed it as a poverty disease in the strict sense,

---

† Since this lecture was prepared J N Morris and R M. Titmuss (*Lancet* 1942 ii 59) substantiate this from an investigation of the social background of juvenile rheumatism based on a study of its morbidity and mortality

We may also look for evidence of chorea in cases of rheumatism rather than for rheumatism in cases of chorea. The dictum, attributed to Sir Thomas Barlow, that "all rheumatic children show chorea, only some more so" is strictly true. In the active phases of infection a subclinical or latent form of chorea is shown by general nervous and mental instability, with fidgetiness under observation, in the prodromal stages there is a tendency to such disorders as tics, night-terrors, enuresis and sleep-walking, and an impression has grown up that juvenile rheumatism is particularly prone to develop in nervous children. This is a difficult conception to any who regard the disease of infective origin, and it is probably more correct to regard the nervousness of the rheumatic child as a result rather than as a predisposing cause of his disease. On the other hand, should he acquire rheumatism, the inherently nervous child is more likely to develop chorea than any other manifestation of the infection.

Subcutaneous nodes.—The threefold clinical significance of these has long been established in their typical form they are diagnostic of rheumatic infection, they denote a severe grade of the disease, being extremely rare in the absence of heart infection and common in association with pericarditis, the course they follow forms a rough guide to changes in the diseased heart. The frequency of subcutaneous nodes is probably lessening, and perhaps, with improved control of the infection, their development is hardly of quite such grave import as it was. Occasionally nowadays a small crop of nodes may develop without any obvious exacerbation of the infection, and children will survive an attack of rheumatism in which scores of acute nodes have been present. The larger type of node which Cheadle regarded as "almost equivalent to a sentence of death" is now rare, but chronic nodes remaining for weeks and months are still seen, the ultimate outlook in both these types remains grave. Thus a rheumatic child showing nodes is suffering from a serious form of the infection and while they persist is in danger, immediate or ultimate.

Pleurisy and pneumonia.—Pneumonia in acute rheumatism, including the peculiar phenomenon described as the rheumatic lung by A. E. Naish, arises as a secondary result of congestion and compression of the lung by the enlarged heart. Pleurisy on the other hand may result as an extension of rheumatic pericarditis and thus be a truly rheumatic inflammation. Impressed by the fact that exposure to cold is an exciting factor in both pneumonia and rheumatism, Cheadle surmised that "probably many of the simple pleurisies and pleuropneumonias we see would be found, on careful inquiry, to be of rheumatic origin", but this has not become accepted.

Rashes.—Erythema nodosum and purpura rheumatica are not to be regarded as true rheumatic manifestations in spite of their frequent association with tonsillitis and quasi-arthritis as Cheadle termed it. This has been recognised for many years though it has been slow to pass into common knowledge. That they are outside the rheumatic picture is shown by the fact that they are hæmorrhagic lesions associated with a minimum of symptoms which can be counted as rheumatic, whereas in true rheumatism hæmorrhages occur only in the severest types. That both may at times be seen in association with true rheumatism is only to be expected, since tonsillar infection is common in all three conditions. Erythema marginatum, on the other hand, may certainly be accepted as essentially rheumatic and is of special interest now that the part played by allergy has come under discussion. Of all rheumatic manifestations it is the one which most closely resembles an allergic phenomenon, and the one of least clinical significance. It comes and goes at any time before, during or after an attack, and appears to have no obvious connexion with alterations in the activity of the infection. For what it is worth, this is an argument against the view that allergy plays an important part in the production of rheumatic lesions.

THERAPEUTIC PROBLEMS

The theory on which the use of salicylic-acid derivatives in acute rheumatism should be based has been the subject of interminable discussion. It is said that although in some phases of juvenile rheumatism salicylate appears to have a definite antirheumatic action, seemingly bactericidal, in other phases its results are too disappointing to allow of such an explanation. At one time some held that its use was actually dangerous, since it served only to mask without subduing the activity of the disease, and others attributed to it the albuminuria, anæmia and the mental and cardiac depression which are so commonly the effects of the disease itself. Probably most informed opinion would nowadays subscribe to R. Lightwood's description of its use as that of a hosepipe not quite long enough to extinguish the conflagration. Nevertheless in practice salicylate is widely accepted as an antirheumatic drug and is even used as a therapeutic test in diagnosis. As long as a discreet silence is maintained about the theory underlying its use it is employed by everyone without hesitation as an antirheumatic remedy.

Much of the difficulty arises from a failure to think out precisely what a specific antirheumatic remedy would be capable of accomplishing in juvenile rheumatism and what would be its limitations. Setting aside the tendency towards recrudescences and relapses, symptoms may be produced by acute inflammatory interstitial processes or by the persistent poisoning of the parenchyma of the organs, notably of the heart and probably of the brain. Evidently the effect of an antirheumatic remedy would be at a maximum in the first and at a minimum in the second set of symptoms. Is this not in line with what is observed in the salicylate treatment of rheumatic infection? In the acute febrile phases of the disease, whether in the tonsils, joints or heart, the drug acts as though it were controlling the activity of the infection the temperature falls, the local lesions subside and arthritis ceases to develop in fresh joints. That this satisfactory result is due to the drug seems confirmed by the frequency with which recrudescence follows its premature withdrawal. But in the more chronic cases, especially where the child is saturated with the poison of the disease and the muscle cells of the heart are degenerate, it is not to be expected that the antirheumatic action of any drug will produce much in the way of an immediate improvement. The action of salicylate is further handicapped by its irritant effect on the stomach, especially in cases already predisposed towards vomiting by the presence of severe cardiac dilatation. The sulphonamide derivatives fail to control the acute phases of rheumatic infection once established. This fact is of theoretical interest to those who accept the streptococcal causation of the disease.

Pathological Problems

The pathological changes in juvenile rheumatism are known, it is with their interpretation that we are here concerned. The pathology of the disease confirms the physician's view of it as a generalised infection. The signs discovered at autopsy—the pericarditis and endocarditis, pleurisy, periarthritis and synovitis, with perhaps nodes under the skin and in the pericardium—all suggest an infection by some agent disseminated through the blood-stream. After making every allowance for the peculiar nature of the disease process, there seems no valid argument against this straightforward explanation. The histological lesions have been regarded from the first as the tissue-reactions to the infecting agent of rheumatism, but owing to their difference from the changes found in other infections this explanation has been called in question. Yet no alternative seems acceptable, for wherever rheumatic lesions are found their peculiar histology is the same, whether we examine the macroscopic lesions which seem so patently the results of infection or the hidden changes in the myocardium. By what route are the valves infected? Are we still to be bound to the belief that, after some preliminary damage to the valve, the endocarditis is set up from the blood within the chambers of the heart rather than through the coronary circulation? The evidence supporting the first and older alternative is well known, though it has been weakened by recent experiments demonstrating the precise distribution of the coronary blood-supply, but it is not on the face of it a likely explanation, and the appearance of a mitral valve recently infected for the first time does not support it. A preferable presumption is that the valves, like the myocardium, are infected through the coronary circulation.

always rarer in children than adults, has now virtually disappeared at any age; pericarditis which in 1880 was found in about 13% of inpatients with acute rheumatism had decreased to 5% by 1914, and is no doubt considerably less common now, subcutaneous nodes, so closely associated with pericarditis, seem also to be less in evidence than they were 30 years ago. If the disease is steadily diminishing in severity it almost necessarily must be diminishing to some extent in frequency. These encouraging results may be attributed to improved social conditions, a better appreciation of the clinical aspects of the disease, and the routine use of the salicylic-acid derivatives. Again, the infection shows a distinct prodromal stage, it is rare for an attack of serious rheumatism to develop suddenly in a child—in most instances the catastrophe has been preceded by months of rather indefinite ill health with sore throats, muscular pains and symptoms of nervous instability the significance of which has been overlooked or misinterpreted. Removal of tonsils, too, assists our efforts to control juvenile rheumatism and its more serious results. Better supervision could be ensured by notification, attention to housing details, special facilities for school attendance, treatment of infected tonsils, establishment of rheumatism supervisory centres, and provision of special beds in heart homes or hospital-schools.

Rheumatism in children under the age of 16 was first made notifiable in the borough of Paddington in 1927, and has since been adopted in a few other localities. Worked in conjunction with some special scheme for the supervision of rheumatic children it is of value; but it fails to provide a complete return of all cases of rheumatic heart disease in the district because only acute phases of the infection can legally be made notifiable. The assistance of a sympathetic medical officer of health is in practice of more value than the notification of the disease. School arrangements for rheumatic children may need modification, the necessity for irregular attendance or even, as a temporary measure, for half-day attendance may be represented to the authorities, and experience shows that it is usually sympathetically considered. No doubt it is the wish of all concerned that attendance at school should do good rather than harm. On an altogether different footing comes attendance at the special day-schools for physically defective children. These "PD schools" are of the greatest value to rheumatic children. Those attending them are driven to school and back, they are rested and fed during their school-hours, and their whole regime is beneficial and free of the dangers of attendance at ordinary elementary schools. Open-air special schools are as a rule unsuitable for rheumatic children.

The closeness of the relationship between tonsillar infection and juvenile rheumatism in all its phases can hardly be over-emphasised. The figures obtained at the Paddington Green Children's Hospital demonstrated that 89% of rheumatic children showed infected tonsils, and that the chance of spontaneous cure was well under 5%, and limited to such cases as had shown no more than a single attack of acute tonsillitis. Thus the call for the removal of diseased tonsils can hardly be questioned on theoretical grounds. In practice the value of this procedure is shown not so much by the prevention of further attacks of rheumatism as by the modified severity of the infection, so that danger to the heart is much reduced; indeed it may be claimed that it is exceptional for permanent heart disease to develop for the first time in a tonsillectomised child. Thus, in a series of children admitted for rheumatism to the Paddington Green Children's Hospital, all of whom showed infected tonsils, the incidences of chorea, arthritis and active carditis were 40%, 52% and 50%. In the same children readmitted for relapses of sufficient severity to need inpatient treatment, these figures for the same manifestations of rheumatism were 78%, 5% and 5%, that is to say, the relapses consisted largely of uncomplicated chorea. The same phenomenon is seen in the rheumatism of tonsillectomised children taken as a whole. That this is no mere chance is suggested by the fact that in children with completely healthy tonsils, uncomplicated chorea is the main symptom. In the well-known figures compiled in America comparing the illnesses of tonsillectomised children with those in children for whom tonsillectomy had been advised and refused, the most significant difference is the drop in the percentage of acquired heart disease in the tonsillectomised group. Lastly, the freedom from spontaneous tonsillitis enjoyed by tonsillectomised rheumatic children, and the smoothness and rapidity of their convalescence from acute attacks, suggest a significant modification of the infective process. Thus removal of diseased tonsils in juvenile rheumatism is both theoretically and practically a correct procedure. Operation should therefore be resorted to where the state of the heart permits, and expert assistance for this purpose should be at hand wherever the care and treatment of rheumatic children are undertaken. The success of operative treatment is, of course, likely to be greater in early than late stages of the disease.

Rheumatic children need more special supervision than is possible in an ordinary outpatient department, in particular they require repeated surveys to see that they are keeping well. Hence special rheumatism supervisory centres have been established to which the patients are summoned for periodic re-examination. To prevent heart disease it is essential to attract early cases of rheumatism to the supervisory centre, and the word "rheumatism" should therefore appear in the name of the centre. The public need teaching that rheumatism is the cause of heart disease in children, and to use the term "cardiac clinic," which conveys little to the minds of the poor, is to defeat the object of the scheme. The physician in charge must be content to supervise children in the earliest stage of rheumatism, the majority of whom show no evidence of established heart disease. The centre must be capable of dealing with every phase of juvenile rheumatism, from the removal of tonsils to the treatment of severe acute attacks, and it is therefore ideal for the centre to be a special department of a children's hospital. The first of these centres in London was opened in October, 1926, and in 1938 there were about 20 such clinics at work, many of them attached to metropolitan children's hospitals or under the management of the London County Council.

The centre receives patients from the wards and outpatient departments of the hospital for supervision during quiescent phases of the disease as well as from school medical officers, private practitioners and the medical officer of health. It reports complaints of housing conditions to the public health authorities, makes special arrangements for school attendance, issues instructions to parents on the care of their children, treats all phases of the disease and makes recommendations for lengthy inpatient treatment if required. The cost of such a centre is low, and it can be organised to deal with a large number of patients. Judging by 10 years' experience in charge of such a centre, the results obtained are satisfactory, and real deterioration in the cases under supervision is surprisingly rare.

Facilities for inpatient treatment, combined with education, in heart homes and hospital-schools for children with rheumatic heart disease have been provided both by charitable funds and by municipal hospitals for chronic cases, where these children can be suitably cared for in conjunction with long orthopædic cases. The cost of treatment on these lines is great so that only selected cases can be accepted, nevertheless valuable results are obtained. It might be hoped that lengthy treatment would not only improve the cardiac condition but help to establish immunity against further attacks on returning home. How far these hopes have been fulfilled is uncertain, but failures are not unknown. It does not seem that these special facilities can replace the work of ordinary hospitals nor of supervisory centres, but they are needed to deal with the more severe examples of juvenile rheumatism and to give them their best chance of improvement or recovery.

THE ARCHITECT AND THE HOSPITAL.—The Bristol and District Divisional Hospitals Council, in coöperation with the replanning advisory committee of the Bristol Incorporated Chamber of Commerce and Shipping, have arranged for Mr Charles Elcock, FRIBA, to give a lecture on the future of health and hospitals from an architect's point of view. The lecture will be held in the physics lecture theatre, Royal Fort, University of Bristol, on Friday, Nov. 27, at 2.30 PM.

increasing in frequency as the depths of poverty are approached, but investigations undertaken from the voluntary hospitals have invariably shown it to be more rife in the upper and middle classes of the poor than in the very poorest This point is not unimportant Were juvenile rheumatism strictly a poverty disease it might well be connected with all the concomitants of dire poverty without distinction but if, as seems to be the case, destitution, underfeeding, overcrowding and general squalor are not factors of predominating weight, we must look for some special predisposing factor compatible with comparative poverty to explain the peculiar class-incidence of the disease

Environment —The paramount importance of environment suggested by the class-incidence of juvenile rheumatism, is conclusively proved by the investigations undertaken for the Medical Research Council's report of 1927 These consisted of the examination of four poor-law residential schools filled with about 1800 children from the rheumatic stratum of the juvenile population Had these children continued to live in their own homes it is practically certain that 2–5% of them would have developed rheumatic heart disease by the time that they were due to leave school, yet the mere removal of them from their homes virtually abolished this danger, and over a period of years the incidence of rheumatism was found to be hardly greater than in the schools of the well-to-do

As the class-incidence shows, the experience of these residential schools is not to be attributed solely to an escape from destitution, and it is in itself sufficient to direct special attention to the housing and schooling of the children of the poorer classes Juvenile rheumatism is particularly a disease of industrial cities, as opposed to residential towns or rural areas, and it tends to be specially prevalent in low-lying districts in proximity to water-courses This latter point brings to mind the traditional association between rheumatism and damp, which is further supported by the geographical, climatic and seasonal incidence of acute rheumatism Probably its prevalence near rivers is more directly influenced by the condition of the house itself than that of the site, as is suggested by the freedom from rheumatism of certain well-known riverside public schools, but houses for the poor tend to be built on cheap and ill-drained sites, and although it is true that an architect can build a dry house on any damp site, this cannot be done cheaply Many slum areas consist of old but decently built houses which have only become damp through ill-usage and dilapidation, but the better-class poor among whom juvenile rheumatism is particularly rife for the most part live in small houses, looking comparatively respectable, but badly built without basements on cheap sites A large proportion of these are damp and cold, and cannot be kept otherwise without a consumption of fuel beyond the means of the tenants

To prove the influence of damp homes in predisposing to juvenile rheumatism is difficult, but it is known that the disease is particularly prevalent in families living in basements, and to a less degree in ground-floors of houses without basements Attempts have been made to compare the proportion of damp homes in rheumatic and non-rheumatic families Such an inquiry was made from the Rheumatism Supervisory Centre attached to the Paddington Green Children's Hospital In it only first attacks of rheumatism were investigated, the controls consisted of non-rheumatic families and not merely families containing a non-rheumatic child, and a strict standard of damp was taken, such as mildew in bedrooms With these precautions damp in the home was found to be nearly twice as frequent in the rheumatic (57 5%) as in the control series (30%) As there is no recognised standard of what constitutes "damp" in a house it is difficult to compare these results with those of other investigations undertaken in London, Glasgow, Birmingham, Bath and Bristol In none of these were the differences between the two sets of figures as great as those in Paddington, and in some they were regarded as statistically insignificant, yet it seems at least rationally significant that in every investigation the results pointed in the same direction

The same point may be also investigated by the construction of rheumatism maps in towns, but this method has as yet hardly yielded much definite information In Paddington the area which seems to be most infected far from being the poorest or most overcrowded in borough, but it lies between a canal and an und river

Considering the difficulty of the subject the ev that damp houses predispose to juvenile rheumatism is at least suggestive, and this view gains in attractiveness when it is borne in mind that some special factor in connexion with poverty is needed to explain the peculiar class-incidence of the disease, as has already been pointed out Further, it is arguable that the same housing factor affords an explanation of the relationship between tonsillar infection and the class-incidence of juvenile rheumatism It may well be that, compared with the overcrowded living-room of the slum dweller, the cold unaired rooms of the badly built houses of the better class poor are the more likely to predispose to tonsillar infection and juvenile rheumatism

Schooling —The attendance of the children of the poor at the elementary day-schools is under compulsion, and this bears hardly on the physically subnormal child, particularly on the rheumatic child whose attendance may need to be irregular Further, from the point of view of exposure to damp and cold, it is impossible to overlook the difference between the well-shod and well dressed children of the rich with facilities for changing and drying wet clothes at their day-schools, and the conditions obtaining in the poorer classes

Tonsillar infection —Chronic infection of the tonsils as a factor in the production of juvenile rheumatism is well recognised In the Paddington figures only 11% of rheumatic children showed normal tonsils

Heredity —It is questionable if hereditary predisposition plays the important part assigned to it by earlier writers The clearer recognition of environment as an important factor in the production of juvenile rheumatism tends to minimise the influence of heredity, and the experience of the poor-law residential schools shows that hereditary predisposition is in practice no bar to prevention of the disease

Other factors —Dietetic factors appear to play no important part in predisposing to juvenile rheumatism The influence of geographical factors, as shown by the world distribution of the disease, presents interesting problems on which further information is required They are, however, outside the scope of these lectures

PREVENTION AND CONTROL

Juvenile rheumatism is found among the children of the poor, attending elementary day-schools under compulsion, and showing chronic tonsillar infection The basic measures needed for prevention are sociological rather than medical to raise the standard of living of the poor in general, and to improve housing conditions in particular So far public opinion in regard to housing has hardly advanced beyond the idea of slum-clearance The Royal Institute of British Architects, whose assistance in this matter is gratefully acknowledged, published in 1929 a *Report on Damp Houses* which made depressing reading at a time when new houses for the poor were being built in such great numbers Investigating a series of damp houses of various types, all of which were less than ten years old, it was found that, excluding damp due to faults of maintenance, the damp was due to porosity or faulty construction of walls in 40 1%, and to absence of, or defects in, damp courses in 32 6% It was pointed out that "all codes of building by-laws, and the conditions on which certain relaxations of by-laws have been permitted, are alike in calling for an adequate damp course, consequently its absence in new buildings must imply failure to comply with this by-law, while defects arise from improper compliance or the use of damp course materials of inferior quality" The comment was passed that this state of things in new dwellings was surprising, and the Report recommended that "the erection of dwelling-houses should be subject to stricter technical supervision, whether by architects engaged to supervise the work or by properly qualified officers of Local Authorities"

Three considerations favour the prevention of juvenile rheumatism first, acute rheumatic infection has lessened materially in severity in the last 50 years, as the decrease in frequency of the three most serious manifestations of the disease shows Hyperpyrexia,

SUMMARY

The incidence of sulphonamide sensitisation may be minimised if (1) medication is restricted to 7 days or less whenever possible, (2) small doses are used initially for certain chronic infections associated with a chronic infective focus, (3) desensitisation is undertaken immediately if eighth day "allergic" sensitisation is encountered, and (4) exposure to sunlight is restricted during chemotherapy

The drug should be withheld if Werner's test indicates drug retention

In cases with photosensitisation recent work suggests that the drug may safely be continued if further exposure to sunlight is avoided

THE Hertfordshire County Council has been exceptionally active in the organisation of school canteens and British restaurants 'One of the centres opened on Sept 18, 1939, claims to be the first to cater for children from the evacuated areas Early in this year there were over 100 feeding centres extending to the schools of the more remote villages These communal meals are, therefore, playing an important part in the nutrition both of schoolchildren and the general population, and the adequacy of the meals is of practical importance This report deals with the amount of vitamin C provided

The investigations were made in three areas, the first includes centres A to F, the second centres G to M, and the third centres N to R Three periods were covered at centre A the meals were examined mainly during a time when vegetables were scarce, at centres B to M during an intermediate period, and at centres N to R when early green vegetables had become abundant (table I)

METHODS

At centres A to F and N to R small weighed samples were put immediately into bottles containing a solution of metaphosphoric acid, or of metaphosphoric and trichloroacetic acids, and the ascorbic acid was estimated as soon as possible At centres G to M samples were placed in glass jars which were taken to the laboratory in a freezing mixture and then kept in a refrigerator until analysed The time elapsing between taking and analysis never exceeded 5 hours Estimations were made by the method described by Chappell (1940), with unimportant modifications The time elapsing between the end of cooking and the taking of the samples varied At centres A, B, C and E it was not more than a few minutes At F it was not more than 10 min On the first 3 days the samples at D were taken directly the food was cooked At centre K food was cooked in two instalments ready at mid day and 1 PM, two pairs of samples were taken, one pair immediately after the food was ready at midday and one after 30 min At centres G to J and L and M only one instalment was cooked and the vegetables were kept hot in pans until wanted Samples were taken at these centres at intervals up to 100 min after cooking was completed At centres N to R samples were taken up to 45 min after the first meals were served, but, as noted later, at centre Q this might be a considerable time after cooking was finished

FINDINGS

Potatoes were served at all meals except one, on a Monday, at centre A, here it was not possible to peel the potatoes for 600 people in the morning in time for cooking, and it was thought inadvisable to keep them peeled over the weekend Green vegetables were served more often as the season advanced, only twice in 9 meals at A, ten times in 41 meals at centres B to M, but fourteen times in 17 meals at centres N to R Raw carrot was served three times, at the school canteens C and M a raw vegetable dish containing raw greens was supplied regularly once a week At centre G salads were served on Fridays At school-centre P watercress was served once a week, when in season, in approximately 20 g portions, though it was useful when the supply of vegetables was uncertain, it must be remembered that 20 g will provide only about 12 mg of ascorbic acid

There were wide differences between the amounts of ascorbic acid found per 100 g in different samples of the same type of vegetable (table II), these differences were found between samples served at the same centre on different days—for example, 2 5 mg per 100 g of potatoes at centre F on April 20 and 6 mg on April 22 Duplicate samples were taken at 19 of the meals served in the group G to M The average difference between the amounts of ascorbic acid per 100 g of two samples of potatoes taken at the same meal was 33 4% of that in 100 g of the sample that contained the lower amount In seven instances this difference was under 10% and in four over 50% Similar differences were found between samples of other vegetables The number of samples of

SULPHONAMIDE SENSITISATION

DAVID ERSKINE, MD LOND, DPH
MEDICAL OFFICER TO THE VENEREAL DISEASES AND DERMATOLOGICAL DEPARTMENTS, GUY'S HOSPITAL, DERMATOLOGIST EMS

THE oral administration or local application of a sulphonamide compound may be attended by various manifestations of intolerance, which may be due to a direct toxic action of the drug or to some form of sensitisation The sensitisation phenomena are of several types Reactions are occasionally encountered early in treatment, sometimes possibly as a result of the liberation of toxins from some chronic infective focus and sometimes on account of an acquired "allergy" to sulphonamides from some previous administration of the compounds Many writers have reported photosensitisation during treatment, but the reaction most commonly seen is an "allergic" sensitisation which develops between the eighth and tenth day of medication and may persist for long periods unless the condition is recognised and controlled The incidence of this allergic sensitisation does not appear to be in any way associated with an allergic family history and depends more on the duration of chemotherapy than on the total dosage administered Salvin (1937) and others have reported positive patch tests, but this local reaction appears to be unreliable and is not always obtained

Immediate symptoms of intolerance are often experienced during the first 48 hours of treatment and may cause depression, headache, nausea and vomiting, they tend to become less troublesome as medication continues beyond the second day Serious toxic effects of the drugs on the hæmatopoietic system have mostly been reported after prolonged administration of the drugs with a total dosage of over 50 g The so-called "drug-resistance" sometimes caused by inadequate dosage may on other occasions result from some type of sensitisation

An immediate toxic effect is occasionally encountered at the beginning of treatment in certain chronic cases, thus an erythematous or maculo-papular rash may develop locally early in the sulphonamide treatment of a chronic abscess Barber (1941) has described early sensitisation of this type during the treatment of lupus erythematosus, the patients experienced severe nausea, vomiting and diarrhœa with considerable malaise and pyrexia, and some developed a generalised scarlatiniform eruption during the first 48 hours of administration The condition may possibly be the result of the liberation of toxins into the circulation from the therapeutic effect of the drug on some chronic infective focus The occurrence can be largely prevented by recognising the possibility of reaction in such cases and beginning sulphonamide medication with small doses and increasing to a more effective dose in the second or third day, this procedure is not justifiable, or necessary, in acute cases as it is likely to lead to drug resistance In this way, presumably, a flooding of the system with liberated toxins is prevented for therapeutic effects can thus be obtained without severe general reactions in this type of case

Light sensitivity, or photosensitivity, is not infrequent during sulphonamide therapy and it is now recognised that excessive exposure to sunlight should be avoided as far as possible during chemotherapy The condition occurs as an erythemato-vesicular eruption on the exposed parts of the body In my experience the rash usually appears during the first week of treatment and has often been associated with evidence of liver damage, in some cases there has been an excessive urobilinuria and a positive van den Bergh test and the drug has therefore been discontinued Park and Platts (1942) have recently reported cases of photosensitisation in which it has been possible to continue medication without ill effects if further exposure to sunlight is avoided, and some of their cases have received further treatment with sulphonamides later without developing evidence of light sensitivity, although exposure to sunlight was not restricted Newman and Sharlit (1937) reported cases of light sensitivity which relapsed on further exposure to sunlight even though no further sulphonamide was given

The most common sensitisation to sulphonamides is an allergic type of reaction which usually appears between the eighth and tenth days of treatment, but occasionally may not develop until the fourteenth day The condition resembles serum sensitivity both in the time of onset and in the type of reaction It may occur as "drug fever" with malaise and pyrexia, but this is not invariable, and there may or may not be a skin eruption, nausea and vomiting Various types of skin rash are seen (Erskine 1939a), these tend to be generalised and may be urticarial, morbilliform, scarlatiniform or rarely purpuric, an eruption resembling erythema nodosum is probably the most frequent type seen during medication with sulphathiazole Similar eruptions may appear at this time with evidence of drug retention and do not seem to be true sensitisation phenomena, it is important that the two conditions should be differentiated, for the sensitisation reactions clear much more rapidly on desensitisation by continued therapy and later complications can be prevented, whereas the type with drug retention call for cessation of chemotherapy to prevent an increase in symptoms and toxic effects Werner (1939) described a simple test to demonstrate sulphonamide excretion in the urine, and this test may be utilised to differentiate the two types of reaction occurring about the eighth day of sulphonamide treatment With "allergic" sensitisation sulphonamide excretion is normal, but with "drug retention" Werner's test shows reduced excretion by a negative or weakly positive test, and there is often albuminuria and sometimes well-marked urobilinuria

Werner's test—1 c cm of urine is diluted 10 times in a test-tube and a few drops of Werner's solution (3% *para* dimethylaminobenzaldehyde in 7% sulphuric acid) are added A flavine yellow colour develops immediately in the presence of sulphonamide An estimation of the efficiency of excretion can rapidly be obtained with a little experience of the test in the routine examination of urines from patients taking varying doses of sulphonamides Diminished excretion and probable drug retention results in negative or weakly positive tests, the latter showing a very pale yellow colour change on adding Werner's solution, as opposed to the strong flavine yellow colour obtained in normal excretions

When there is drug retention, sulphonamide treatment should be discontinued and elimination assisted with fluids by mouth and saline diuretics When the sulphonamide excretion is normal, administration should be continued with care in the same or reduced dosage for 48 hours with the object of desensitising the patient This continuation of therapy should only be attempted when the patient is under continued observation so that any exacerbation can be immediately controlled, and a blood-picture should be examined whenever possible in view of the remote possibility that a severe granulocytopenia may develop at this stage Continuation of the drug may be advisable in view of the desired therapeutic effect, but it is also of considerable importance to desensitise the patient whenever possible because of the extensive use of these drugs for so many common illnesses and the fact that a patient developing sensitivity of this type may remain allergic for a long period Sometimes the first tablet given months later may provoke an immediate return of the dermatitis with general symptoms and these reactions may occasionally be of an alarming nature I have previously reported a case (Erskine 1939b) in which one 0 5 g tablet of sulphapyridine given twelve months after the original sensitisation caused œdema of the larynx Delayed reactions have not been observed when desensitisation was undertaken at the time of the reaction

If chemotherapy is restricted, whenever possible, to a seven-day period the incidence of allergic sensitivity is considerably reduced and I have encountered but few cases since recognising this factor three years ago

Sensitivity is liable to develop with any of the sulphonamide drugs and there is little evidence that any particular compound is less likely to cause reactions The condition almost invariably appears between the eighth and tenth days of treatment and most cases appear to depend more on this time factor than on the total dose employed Very occasionally, delayed reactions appear up to 48 hours after chemotherapy has stopped, so that administration for more than six days makes allergic sensitivity a possibility *It is important* to recognise that absorption from local applications as well as oral or parenteral administration may lead to sensitisation phenomena the one centre (O) that had a garden supplied by far the most ascorbic acid, mainly owing to the large helpings of green vegetables As is shown by the example of schools E and F, the effect of the school garden on the supply of ascorbic acid depends largely on the type of vegetable grown

A further study was made by two of us (F W) and W W P) on 17 meals served at school canteens S, T, V, W and X and British restaurant U, all situated in towns The schools had no gardens

Special precautions were taken to ensure accurate estimation A normal portion of a separate vegetable or of a whole serving for one person was taken while the meal was being served This was cut up and well mixed on a plate with knife and fork and divided into four approximately equal portions, two of which were examined at an EMS laboratory at Watford and two at the Ovaltine Research Laboratories Each part was put in a weighed glass jar containing 20 ml of 25% metaphosphoric acid, prepared on the same day, and at once well mixed by shaking Samples were brought to the laboratories within one hour and the ascorbic acid estimated at once Special attention was paid to the accuracy of the estimation As experience showed that assays of ascorbic acid in foods may be too low owing to incomplete extraction, the solid was ground thrice with sand under metaphosphoric acid solution, the extract squeezed through muslin and the residue ground with further sand and metaphosphoric acid The resulting extract was made up to a known volume and clarified by centrifuging The results on coloured solutions were checked by the potentiometric method of Harris, Mapson and Wang (1942) The estimates at the two laboratories agreed well, for example the amounts of ascorbic acid found at the two laboratories in one meal were 26 6 and 27 4

The first of these estimates was made on May 13, the others on May 21 and during June and July The amounts of ascorbic acid found in potatoes up to the beginning of July were less than in the series A to R because of gradual loss of vitamin C in old potatoes on storage After the first week in July new potatoes became available and the average rose to nearly 12 mg per 100 g The amounts in green vegetables ranged from 19 to 53 mg per 100 g Differences between duplicate samples were similar to those found in the previous series The effect of keeping hot after cooking was studied at the canteen of an industrial firm At 11 30 AM the amounts of ascorbic acid in two servings, weighing 140 g, of mixed vegetables (potatoes, greens and carrots) were 18 6 and 21 6 mg per 100 g, mainly contained in the greens The amounts in samples weighing 140 g, taken at 1 30 PM when all servings had been distributed, were about one-third less—13 2 and 13 6 mg The vegetables had been kept on a hot plate at about 80° C

An attempt was made to check the estimates of the size of helpings by finding the total amount of vegetables used and the number of persons supplied The amounts of vegetables used per week in May at school S would supply each child with 320 g of potatoes, 172 g of greens and 57 g of carrots per week; actual helpings weighed were potatoes 108, 124, 118 g, greens 38 g At school T during a week in June the totals would supply each child with 150 g of potatoes and 62 g of greens per day, not allowing for waste; these are in fair agreement with the actual samples taken Greens were served on three out of five days of the week The largest difference between helpings of vegetables at the same meal was 31% The average helping of potatoes actually weighed (when these were weighed separately) was only 115 g, and the average total weight of vegetables in a serving 196 g The amount of ascorbic acid per meal ranged from 0 9 to 29 6 mg, and averaged 16 mg up to the end of June In July, when new potatoes and larger quantities of greens were available, the average amount rose to 48 mg, and ranged from 29 to 79 mg per meal As might be expected, the meals showed considerable seasonal variations in their vitamin-C content

DISCUSSION

In most cases little more ascorbic acid is taken during the day than is supplied in the dinners served at these canteens A small and doubtful amount is contained in milk and 1 mg or so may be obtained from meat and jam The meals should, therefore, meet the whole of the day's requirements Actually the average amount in the meals, served before vegetables were plentiful, was little over half the standard of 30 mg proposed by the technical commission of the League of Nations (1938) and regarded by Bacharach and Drummond (1940) as a marginal requirement If requirement of ascorbic acid is proportional to the body-weight, the dinners may be considered just to meet the requirements of schoolchildren during the transition period before green vegetables are plentiful, during the worst period the amounts supplied are not adequate for children This can hardly be regarded as satisfactory, but the amounts of ascorbic acid in meals supplied at these centres in Hertfordshire are no less than found at other school canteens and British restaurants, nor than amounts obtained at home In January, 1941, one of us kept a record of his diet, the average intake of ascorbic acid was 16 mg per day, in 1942 with more attention to the supply of green vegetables the average was well over 30 mg

Study of ways to avoid losses of ascorbic acid in cooking suggests that the supply of green vegetables is of considerably more importance than the method of cooking The difficulty is to get the green vegetables At centre A it was almost impossible to get any greens from March 16 to April 27 However, abundant supplies of savoys were ready in private gardens by April 3 and the garden of school E was supplying sprouting broccoli in abundance by April 20 The garden of school F was not so well used, it was supplying potatoes right up to April, although potatoes were cheap and abundant, but did not produce any of the early greens The British restaurants and schools in towns have to depend on market gardeners who as a rule grow vegetables more suitable for transport than sprouting broccoli savoy or kale

The supply of ascorbic acid could be increased by eating green vegetables raw This would, however, solve only one of the difficulties associated with vegetables The supply of vitamin A from animal sources is fixed at a low level by the rationing of butter, margarine and cheese, the control of the milk-supply during the winter months and the scarcity of eggs Requirements must be made up from the carotene of green vegetables and carrots The vitamin A values of the average helpings of green vegetables and carrots are only some 1300 and 6000 international units respectively The 13 servings of green vegetables and 13 servings of carrots in the 50 meals of series A to M spread out over 50 days would supply only about 1600 IU per day It would be no more, possibly less, if the vegetables were eaten raw The supply of green vegetables should therefore be increased in order to provide sufficient vitamin A

We wish to thank the County Education Officer for his encouragement of this investigation, Miss J Organ, Ph C, for carrying out many of the estimations, and the staffs of the school canteens and British restaurants for the help and information they provided

MINISTRY OF HEALTH WINTER HEALTH CAMPAIGN —The Ministry of Health, with the coöperation of the Ministry of Information, is launching another winter health campaign, and will renew its attack on the careless cough and sneeze by persistent education on the dangers of droplet infection H. M Bateman has produced another set of four cartoons and has chosen for his backgrounds a cinema, a lift, a suburban train and a canteen. A special poster has been designed to stress how the war effort is hindered by the spread of colds and influenza in factory, workshop and office A flashlight photograph shows the germ spreading effects of an unguarded sneeze, while a panel points out that time lost every year through colds and influenza is the equivalent in production of 3500 tanks, 1000 bombers and 1,000,000 rifles potatoes examined was sufficient to justify comparison between the three groups The means agreed well group A to F, 5 7 , group G to M, 6 4 , group N to R, 6 13 These means are rather lower than those found by one of us earlier in the year at a hospital (7 6), at home (7 7) and in school canteens and British restaurants in London (6 7) , and definitely lower than the 8 mg found by Olliver (1940) This was probably because of the lateness of the season The average amounts found in other vegetables agree well with the figures found by others (e g , Olliver 1940, Mathews and Bacharach 1941, Harris and Olliver 1942) The lowest amount found in any green leafy vegetable was 9 mg per 100 g , this was a sample of thousand-headed kale, cut on a Friday and cooked on the following Monday The amounts in cooked carrots were, on the whole, below the average found by Olliver (1940) , this, again, may have been due to the fact that they had been kept for a long time after being lifted.

At centre A green vegetables were crammed into a string bag and placed in a volume of boiling water, little more than was needed to cover them, in a large boiler It might be expected that this method of cooking would favour destruction of ascorbic acid, since the vegetables in the middle must be heated up slowly Unfortunately the studies at this centre were made when green vegetables were scarce and only two samples were examined , but there was no evidence of excessive destruction of ascorbic acid in these two as they contained 10 5 and 38 mg per 100 g A further study will be made at this centre in summer At centre Q the method of cooking was similar, but a wire basket was used instead of a string bag Apart from this the vegetables at this centre were cooked in instalments from 10 AM onwards and kept in a hot cupboard at 65°–70° C until needed The batches put in last were taken out first, so that some batches were not served until over 3 hours after they had been put on to cook Nevertheless, the sample of green vegetables (kale and sprouting broccoli) taken at this centre contained 57, 17 5, 19, 37 6, 44 5 mg per 100 g It is possible that the extreme difference between samples taken on the same day may be due to the long keeping of the second sample

Nor was there any evidence that the destruction of ascorbic acid, in the samples of vegetables in group F to M, kept hot for a considerable time, was much greater than in samples taken shortly after cooking The mean value for the 14 samples of potatoes which had been kept hot, over a low gas or in an oven, for not less than 40 min after cooking was 6 6 mg per 100 g , while the mean for 25 samples kept for under 40 min was 6 3 Sprouting broccoli which had been kept hot (commonly on a hot plate with the temperature falling from about 100° C to about 65° C) for at least 100 min contained 14 5 and 15 5 mg per 100 g When small samples of vegetables are kept hot on a water bath the loss of ascorbic acid is fairly rapid, though variable , 40% may be lost in an hour Large samples in covered containers probably lose ascorbic acid less rapidly because oxygen diffuses into the substance more slowly

In most of the centres vegetables were cooked in dixies , the method did not differ from that used in domestic cooking except that it was on a larger scale In the smaller schools the dinners were all served within 15 min of the end of cooking Large amounts of ascorbic acid are extracted from vegetables by the water in which they are cooked , this is one of the chief causes of loss This loss could be reduced if a series of batches of vegetables were cooked in the same water (Macrae 1942) , and if cooking water were used for making soups and gravies the ascorbic acid extracted would not be lost to the consumers However, serial cooking would entail difficulties in centres where one batch of vegetables only is commonly cooked There are practical objections to the use of the cooking water, and it was rare to find that all of it was used

Most manageresses of communal feeding centres have been impressed with the belief that potatoes lose a large proportion of their ascorbic acid if they are peeled and kept in water overnight Two of us have tested this belief , one (J R M) found no evidence of loss even if the potatoes were cut in pieces, measuring about 5 by 3 by 3 cm , the other (G V J) found evidence of a slight loss and of a serious loss in one instance only (table III)

TABLE III—EFFECT OF PEELING, KEEPING AND COOKING ON THE ASCORBIC ACID CONTENT OF 6 SAMPLES OF POTATOES

Potatoes	Ascorbic acid (mg per 100 g)					
Raw	18 5	17 1				
After peeling	16 5	20 0	17 2	8 9	12 8	13 3
Peeled and kept overnight	16 0	18 0	13 4	8 3	10 2	13 4
Peeled, kept overnight and cooked	15 8	9 7*				

* Kept hot for 2 hr after cooking

TOTAL ASCORBIC ACID IN THE MEALS

In order to estimate the amount of ascorbic acid supplied by the meals it is necessary to know the size of the helpings This is not easy A fair estimate of the size of an average helping of potatoes can be calculated from the total amount supplied and the number served , 14% may be assumed to be wasted with the peel For example school E used 28 lb per day for 80 children, and school D 112 lb per week for 12 small and 25 big children and 4 adults The size of the average helping so calculated agreed with that found by weighing samples However, these were small schools where all the serving was done by one or two people , the whole process of serving could be watched and fair samples chosen for weighing Children's helpings varied with the age—for example, at centre N the average helping for juniors was 144 g and for seniors 270 g But there were wide variations not due to age between different centres , thus the average helping over 3 days at centre G which supplied children of all ages was 210 g , but it was only 75 6 g at centre H which supplied children of all ages and adults At the centres G to M, where two sample helpings were weighed at most of the meals, the average difference between the weights of two was 29% of the weight of the smaller , in 3 cases the difference was over 50% and in one it was 128% There were similar wide differences between the weights of helpings of other vegetables, both between duplicates taken at the same meals and between the helpings at different centres For example, at N the average helping of green vegetables was 34 g for juniors and 36 g for seniors , while at school D it was 123 g Occasionally helpings of carrots and parsnips were unexpectedly large The differences between the total amounts of ascorbic acid contained in the other vegetables of duplicate samples of meals at centres G to M were less than those between the weights of the duplicate samples of potatoes The mean difference was 17% and in no instance was it over 40% The mean total ascorbic acid in the members of each pair that contained the larger amount was 18 mg and the mean of the other members that contained the smaller amount was 15 5 mg At school N seniors got 75 mg in 3 days and juniors 70 mg

The most striking features is the difference between the series A to F and G to M on the one hand and the series N to R on the other This difference was due to the fact that green vegetables (mainly kale and sprouting broccoli) were served more often in the last series and that the amount of ascorbic acid in the greens served was larger A similar contrast can be drawn between schools E and F The average amount of ascorbic acid derived from a helping of potatoes was nearly 10 mg (table II) This may be regarded as a constant foundation of the day's supply of vitamin C A helping of green vegetables usually brings up the total to over 30 mg With good helpings of swedes or leeks or raw carrots the total is likely to be over 20 mg , but it is likely to be under 20 mg if any other cooked vegetable is used to supplement the potato This does not include vegetables—kohlrabi for example—which are not grown to any great extent Raw green vegetables are usually eaten in small amounts In the one meal included in this series at which they were served 21 g of raw chopped greens supplied 8 5 mg of ascorbic acid and 21 g of lettuce another 4 2 mg

Vegetables for the school canteens were obtained from local retailers, school gardens and (schools B and D) from the gardens of large houses in the neighbourhood In the series G to M the two schools that provided the most ascorbic acid per meal had gardens , In series N to R the one centre (O) that had a garden supplied by far the most ascorbic acid, mainly owing to the large helpings of green vegetables As is shown by the example of schools E and F, the effect of the school garden on the supply of ascorbic acid depends largely on the type of vegetable grown

A further study was made by two of us (F W) and W W P) on 17 meals served at school canteens S, T, V, W and X and British restaurant U, all situated in towns The schools had no gardens

Special precautions were taken to ensure accurate estimation. A normal portion of a separate vegetable or of a whole serving for one person was taken while the meal was being served This was cut up and well mixed on a plate with knife and fork and divided into four approximately equal portions two of which were examined at an EMS laboratory at Watford and two at the Ovaltine Research Laboratories Each part was put in a weighed glass jar containing 20 ml of 25% metaphosphoric acid, prepared on the same day, and at once well mixed by shaking Samples were brought to the laboratories within one hour and the ascorbic acid estimated at once Special attention was paid to the accuracy of the estimation. As experience showed that assays of ascorbic acid in foods may be too low owing to incomplete extraction, the solid was ground thrice with sand under metaphosphoric acid solution, the extract squeezed through muslin and the residue ground with further sand and metaphosphoric acid The resulting extract was made up to a known volume and clarified by centrifuging The results on coloured solutions were checked by the potentiometric method of Harris, Mapson and Wang (1942) The estimates at the two laboratories agreed well, for example the amounts of ascorbic acid found at the two laboratories in one meal were 26 6 and 27 4

The first of these estimates was made on May 13, the others on May 21 and during June and July The amounts of ascorbic acid found in potatoes up to the beginning of July were less than in the series A to R because of gradual loss of vitamin C in old potatoes on storage After the first week in July new potatoes became available and the average rose to nearly 12 mg per 100 g The amounts in green vegetables ranged from 19 to 53 mg per 100 g Differences between duplicate samples were similar to those found in the previous series The effect of keeping hot after cooking was studied at the canteen of an industrial firm At 11 30 AM the amounts of ascorbic acid in two servings, weighing 140 g, of mixed vegetables (potatoes, greens and carrots) were 18 6 and 21 6 mg per 100 g, mainly contained in the greens The amounts in samples weighing 140 g, taken at 1 30 PM when all servings had been distributed, were about one-third less—13 2 and 13 6 mg The vegetables had been kept on a hot plate at about 80° C

An attempt was made to check the estimates of the size of helpings by finding the total amount of vegetables used and the number of persons supplied The amounts of vegetables used per week in May at school S would supply each child with 320 g of potatoes, 172 g of greens and 57 g of carrots per week; actual helpings weighed were potatoes 108, 124, 118 g, greens 38 g At school T during a week in June the totals would supply each child with 150 g of potatoes and 62 g of greens per day, not allowing for waste; these are in fair agreement with the actual samples taken Greens were served on three out of five days of the week The largest difference between helpings of vegetables at the same meal was 31% The average helping of potatoes actually weighed (when these were weighed separately) was only 115 g, and the average total weight of vegetables in a serving 196 g The amount of ascorbic acid per meal ranged from 0 9 to 29 6 mg, and averaged 16 mg up to the end of June. In July, when new potatoes and larger quantities of greens were available, the average amount rose to 48 mg. and ranged from 29 to 79 mg per meal As might be expected the meals showed considerable seasonal variations in their vitamin-C content

DISCUSSION

In most cases little more ascorbic acid is taken during the day than is supplied in the dinners served at these canteens A small and doubtful amount is contained in milk and 1 mg or so may be obtained from meat and jam The meals should, therefore meet the whole of the day's requirements Actually the average amount in the meals, served before vegetables were plentiful, was little over half the standard of 30 mg proposed by the technical commission of the League of Nations (1938) and regarded by Bacharach and Drummond (1940) as a marginal requirement If requirement of ascorbic acid is proportional to the body-weight, the dinners may be considered just to meet the requirements of schoolchildren during the transition period before green vegetables are plentiful, during the worst period the amounts supplied are not adequate for children. This can hardly be regarded as satisfactory, but the amounts of ascorbic acid in meals supplied at these centres in Hertfordshire are no less than found at other school canteens and British restaurants, nor than amounts obtained at home In January, 1941, one of us kept a record of his diet, the average intake of ascorbic acid was 16 mg per day, in 1942 with more attention to the supply of green vegetables the average was well over 30 mg

Study of ways to avoid losses of ascorbic acid in cooking suggests that the supply of green vegetables is of considerably more importance than the method of cooking The difficulty is to get the green vegetables At centre A it was almost impossible to get any greens from March 16 to April 27 However, abundant supplies of savoys were ready in private gardens by April 3 and the garden of school E was supplying sprouting broccoli in abundance by April 20 The garden of school F was not so well used, it was supplying potatoes right up to April, although potatoes were cheap and abundant, but did not produce any of the early greens The British restaurants and schools in towns have to depend on market gardeners who as a rule grow vegetables more suitable for transport than sprouting broccoli savoy or kale

The supply of ascorbic acid could be increased by eating green vegetables raw This would, however, solve only one of the difficulties associated with vegetables The supply of vitamin A from animal sources is fixed at a low level by the rationing of butter, margarine and cheese, the control of the milk-supply during the winter months and the scarcity of eggs Requirements must be made up from the carotene of green vegetables and carrots The vitamin A values of the average helpings of green vegetables and carrots are only some 1300 and 6000 international units respectively The 13 servings of green vegetables and 13 servings of carrots in the 50 meals of series A to M spread out over 50 days would supply only about 1600 IU per day It would be no more, possibly less, if the vegetables were eaten raw The supply of green vegetables should therefore be increased in order to provide sufficient vitamin A

We wish to thank the County Education Officer for his encouragement of this investigation, Miss J Organ, Ph C, for carrying out many of the estimations, and the staffs of the school canteens and British restaurants for the help and information they provided

TOTAL ASCORBIC ACID IN THE MEALS

In order to estimate the amount of ascorbic acid supplied by the meals it is necessary to know the size of the helpings This is not easy A fair estimate of the size of an average helping of potatoes can be calculated from the total amount supplied and the number served, 14% may be assumed to be wasted with the peel For example school E used 28 lb per day for 80 children, and school D 112 lb per week for 12 small and 25 big children and 4 adults The size of the average helping so calculated agreed with that found by weighing samples However these were small schools where all the serving was done by one or two people, the whole process of serving could be watched and fair samples chosen for weighing Children's helpings varied with the age—for example at centre N the average helping for juniors was 144 g and for seniors 270 g But there were wide variations not due to age between different centres, thus the average helping over 3 days at centre G which supplied children of all ages was 210 g, but it was only 75 6 g at centre H which supplied children of all ages and adults At the centres G to M, where two sample helpings were weighed at most of the meals, the average difference between the weights of two was 29% of the weight of the smaller, in 3 cases the difference was over 50% and in one it was 128% There were similar wide differences between the weights of helpings of other vegetables, both between duplicates taken at the same meals and between the helpings at different centres For example, at N the average helping of green vegetables was 34 g for juniors and 36 g for seniors, while at school D it was 123 g Occasionally helpings of carrots and parsnips were unexpectedly large The differences between the total amounts of ascorbic acid contained in the other vegetables of duplicate samples of meals at centres G to M were less than those between the weights of the duplicate samples of potatoes The mean difference was 17% and in no instance was it over 40% The mean total ascorbic acid in the members of each pair that contained the larger amount was 18 mg and the mean of the other members that contained the smaller amount was 15 5 mg At school N seniors got 75 mg in 3 days and juniors 70 mg

The most striking features is the difference between the series A to F and G to M on the one hand and the series N to R on the other This difference was due to the fact that green vegetables (mainly kale and sprouting broccoli) were served more often in the last series and that the amount of ascorbic acid in the greens served was larger A similar contrast can be drawn between schools E and F The average amount of ascorbic acid derived from a helping of potatoes was nearly 10 mg (table II) This may be regarded as a constant foundation of the day's supply of vitamin C A helping of green vegetables usually brings up the total to over 30 mg With good helpings of swedes or leeks or raw carrots the total is likely to be over 20 mg, but it is likely to be under 20 mg if any other cooked vegetable is used to supplement the potato This does not include vegetables—kohlrabi for example—which are not grown to any great extent Raw green vegetables are usually eaten in small amounts In the one meal included in this series at which they were served 21 g of raw chopped greens supplied 8 5 mg of ascorbic acid and 21 g of lettuce another 4 2 mg

Vegetables for the school canteens were obtained from local retailers, school gardens and (schools B and D) from the gardens of large houses in the neighbourhood In the series G to M the two schools that provided the most ascorbic acid per meal had gardens, In series N to R duction of physiological salt solutions or blood was ective This action of potassium phosphate is seen n the absence of anatomical injury of the vegetative centre cells and while they still have capacity to When they are exhausted the drug has not this

This procedure is therefore indicated in all cases hock where there are signs of the weakening of pathetic tonus The best results are obtained when injection is not too long delayed, since after a time nervous centres become exhausted and cease to react

CONFIRMATION IN MAN

nese laboratory results were fully confirmed clinically on the battlefield The technique in man is to inject ne sixth molar solution (isotonic) of potassium sphate (a mixture of potassium hydrogen phosphate potassium dihydrogen phosphate giving a pH of in a quantity of 1–2 c cm directly into the cerebral tricles or cisterna magna

he patient must be in a horizontal position (prefer- y on his left side) with the head lower than the body bent on the chest, the lower limbs must be flexed external occipital protuberance and the first ncal spinous process are identified and the skin ween them shaved and disinfected A graduated ernal needle or an ordinary lumbar-puncture needle nserted exactly in the midline pointing towards the ernal auditory meatus and slid along the occipital e until the atlantoid membrane is perforated (with a king sound) This occurs at a depth of 4–5 cm, nslucent cerebrospinal fluid will escape from the dle after removal of the stylet Since in shocked ients the intracisternal pressure may often be low the ebrospinal fluid often does not flow spontaneously l has to be drawn out with a syringe After 1–2 c cm the cerebrospinal fluid has been withdrawn 1 c cm of solution of potassium phosphate which has been rmed to body temperature is injected with a syringe der such a pressure that it penetrates into the ven- les This method of treatment is simple and can be ily applied at the front The preparation of the tassium phosphate solution is not complicated, but st be done carefully the glass of the ampoules must neutral, the mixture of the monometallic and netallic potassium phosphate (concentration one-sixth lar) can be prepared either from these salts (K_2HPO_4 d KH_2PO_4) or by adding the ortho-phosphoric acid a solution of potassium hydroxide up to pH 7 6

As a rule the effects of this injection are noticed in 1–2 inutes or even sooner the blood-pressure rises and the piration becomes deeper The absence of these effects thin a few minutes is generally due to the fact that the id has not reached the ventricles as a result of the orrect direction of the needle or an insufficient pres- re In those cases one must repeat the operation

Other measures of proven worth in the treatment of ock must also of course be employed blood-trans- ion where this is necessary adequate fluids and utriment by mouth, alleviation of pain, and removal of verely injured tissues which may be a source of bstances harmful to the body, and a possible nidus for fection, besides in many cases causing direct leakage f plasma locally and resultant shock

SUMMARY

The main feature of the final stage of traumatic shock a considerable reduction in tonus of the sympathetic ervous system and a partial increase in that of the arasympathetic nervous system

The most effective means of combating shock in this inal stage is the raising of the tonus of sympathetic erve centres by the direct action on those centres of otassium ions

If potassium phosphate be introduced directly into the ateral ventricles or cisterna magna the potassium ions ill stimulate sympathetic nerve centres and the phosphate (reducing the concentration of ionised calcium) ill cause a depression of parasympathetic centre tone

This measure is indicated in traumatic shock in the hase of decreased sympathetic tonus that is at a omparatively late stage In no circumstances should it employed when there is evidence of sympathetic excita- ion, as sometimes happens in the first phase of shock

It is effective in man as well as in experimentally roduced animals In human cases it must be introduced into the lateral ventricle or cisterna magna to be effective, 1–2 c cm of a one-sixth molar solution of a mixture of potassium hydrogen phosphate and potassium dihydrogen phosphate, pH 7 6, is injected with the patient lying horizontally on the left side with the head at a lower level than the body

Other measures of combating shock, such as transfusion and alleviation of pain, should not be neglected

TREATMENT OF PULMONARY TUBERCULOSIS BY LUNG PUNCTURE

CARLOS ROBERTSON LAVALLE
PROFESSOR OF SURGICAL PATHOLOGY IN THE NATIONAL UNIVERSITY OF BUENOS AIRES

IN an article[1] five years ago I described my technique for the treatment of bone and lung tuberculosis by puncture of what I termed the nucleus of post-allergic focal infection, and I attempted to explain the satisfactory results obtained by suggesting that puncture liberated into the circulation antibodies which had hitherto been confined in the nucleus I was then able to report a favourable reaction to this treatment in 76–80% of about 450 bone cases and in a similar percentage of 200 lung cases I have since extended my series of cases to over a thousand

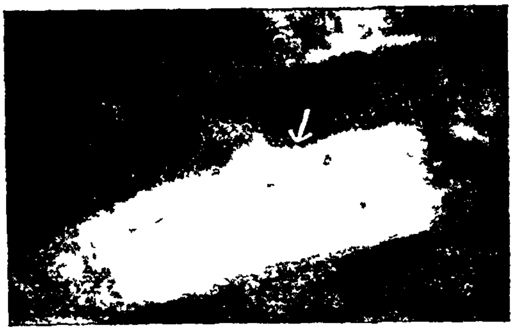

Fig 1—Radiogram showing nucleus (arrow) in second right intercostal space

The nucleus in the lung has been carefully studied by stereoscopic X rays, and has been found to be generally similar to the lesion in bone which I described[2] in 1931 It is sometimes star-shaped and sometimes like a wheel of which the spokes are made up of small lines or dots and the rim is a more or less continuous line or a ring of round dots each about the size of a pin's head The nucleus can often be seen in the ordinary X-ray film, but a series of stereoscopic films may have to be taken before it is identified The shadows, particularly the star-shaped ones are apt to be blurred because of the relatively long exposure used in chest radiography We are aiming at exposures of 1/100 sec in order to eliminate the effects of movement of the lung tissue In the chest radiogram the nucleus appears as a circle about 1 cm in diameter (figs 1 and 2) but it is probably actually a good deal larger The exudative components of the tuberculous process give it a blurred outline, and it is only when definite fibrous tissue has been formed that a clear impression of lines or spots is obtained

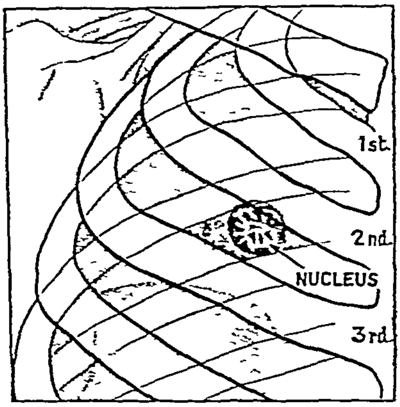

Fig 2—Sketch of radiogram of upper part of right lung to show position and appearance (exaggerated) of nucleus

SHOCK

TREATMENT BY DIRECT ACTION ON VEGETATIVE NERVE CENTRES

ACADEMICIAN LINA S STERN
DIRECTOR OF THE INSTITUTE OF PHYSIOLOGY, ACADEMY OF SCIENCES OF THE USSR, MOSCOW

THE concept of shock is still inadequately defined despite much writing and many observations on pathogenesis and treatment obtained in the laboratory, in the hospital and on the battlefield The existing differences of opinion are in part explained by the fact that the definitions are based on observations made during different phases of shock It is generally agreed that traumatic shock shows two main phases (1) an initial reflex phase following quickly after the injury and irrespective of the amount of blood loss , and (2) secondary shock setting in a few hours after the injury, manifest in weakness, pallor, fall in blood-pressure and a consequent fall in temperature This last phase is similar in many ways to collapse as seen, for example, in typhoid, pneumonia and diphtheria, and is characterised primarily by circulatory insufficiency *An important factor in this derangement of hæmodynamics* is thought to be reduction of blood-volume due to accumulation of blood in the so-called blood depots (liver, kidneys, spleen, and, as emphasised recently, skeletal musculature), plasmorrhœa, leading to reduction in volume of the plasma by leakage through the damaged capillary walls , and actual loss of blood When the loss of blood does not exceed 25% of the total blood-volume, blood-pressure is maintained at a normal level by means of vessel constriction This reduction in blood-volume is compensated by absorption of fluid from the tissue spaces After a few hours hæmodilution is often observed This compensatory process may however prove inadequate if dehydration is present Continued decrease of the volume of circulating blood will finally bring about an abrupt fall in blood-pressure despite vessel constriction The resultant reduction in blood-supply to the tissues, with impaired nutrition and oxygenation, will lead to damage and increased permeability of the capillaries This in turn will permit leakage of plasma through the capillary walls and the development of œdema The diminished plasma volume means an increase in viscosity, and circulation is impeded At this late stage blood-transfusion is of little value since the plasma is not retained in the vessels The diagnosis of shock although difficult to make in the initial stages, later becomes an obvious one from the characteristic symptoms of circulatory insufficiency At this stage the blood-pressure is maintained mainly by constriction of the vessels, and the slightest disturbance—for instance, anæsthesia or a further small loss of blood or plasma—is sufficient to cause a rapid fall in blood-pressure

Experiments made with our colleagues, Rosin and Chvoles, have proved that sensitivity, especially to pain, plays an important part in the development of shock This work showed that irritation of the skin by an induction current for 2–6 hours causes shock, whereas when the skin is previously anæsthetised with procaine much longer electrical stimulation produces no effect Given the same conditions, shock is most easily produced by irritation of the skin on the inner surface of the thigh and of the peritoneum and periosteum, whereas irritation of the dura even for as long as 8–12 hours does not cause shock The rhythm of irritation plays an important part, shock usually appearing much more quickly when the rhythm is quicker The criteria of shock in all these experiments were (1) sudden and maintained fall of blood-pressure with a rapid and feeble pulse, (2) shallow breathing, (3) the absence of reaction to irritation, and (4) lowering of the temperature All these point to a disturbance of the vegetative nervous system

The important rôle played by preceding conditions in the development of clinical shock in man has been demonstrated by clinical observation Excessive tiredness, prolonged insomnia, insufficient nourishment, fear, exposure, loss of blood, and, not least, painful irritation, lead after a transitory and relatively short phase of sympathetic over-stimulation to one of exhaustion and contribute in this way to the development of shock

The results of these experiments show that caused, apart from loss of blood, by a whole circumstances, each of which affects the condition nerve centres Only when all these conditions present does shock develop

COMPOSITION OF THE CEREBROSPINAL FLUID

In studying the clinical picture of shock attention been focused mainly on the functional biochemi changes in the blood and cardiovascular systems the mechanism of shock and its rational treatment prophylaxis are to be better understood attention mu be turned to the functional condition of the nerve cent to their metabolism, and to the nature of the cereb spinal fluid surrounding these centres The import rôle played by the CSF in the maintenance of functional condition of the nerve centres has be established by many years' clinical and laborat observations[1] Not only the penetration of abnorm substances from the blood into the CSF through blood-brain barrier, but even an altered equilibrium electrolytes in the CSF may be enough to induce seve changes in the nerve centres, sometimes fatal In som cases we have observed that changes in the potassiu and calcium ion concentration were related to the develo ment of a shock-like state (Voskressensky, Nodia) T injection of small doses of calcium salts directly into t cerebral ventricles induces a condition of great depressi under experimental conditions, while a minimal dose potassium salts will produce excitation, sometim leading to the animal's death by exhaustion Moreove the changes in the vegetative nervous system induc by strong peripheral stimulation are closely related the pre-existing chemical composition of the CSF, a in particular to the concentration of potassium an calcium in it

Attempts to combat shock must be primarily directe towards restoration of the circulation In man instances however these efforts to combat shock by dire action on the cardiovascular system may fail becaus in the presence of an intact blood-brain barrier, they d not affect the condition of the central nervous system Many drugs are without action on the central nervou system when injected peripherally, whereas when directl injected into the CSF they give a maximal and powerf effect Moreover, their action when introduced directl into the CSF may be exactly opposite to that obtaine when they are injected peripherally When injecte into the subdural or subarachnoid spaces, many drug are less effective than they are when introduced directl into the lateral cerebral ventricles The most importa agents in this respect are potassium and calcium

EFFECT OF INJECTING POTASSIUM

Laboratory experiments by G J Chvoles at th institute have shown that the direct introduction potassium ions into the lateral ventricle or cistern magna gives rise to strong excitation of the sympathet nervous system in cases of experimental traumati anaphylactic peptone and histamine shock Phosphat ions, by reducing the concentration of free calcium ion lead to a substantial decrease in the tonus of the para sympathetic centres Seemingly as a result there is increase in the quantity of circulating fluid due to mobi isation of blood from the blood depots and fluid from th tissue spaces Chvoles's animals were in a state of shoc as a result of serious wounds, with or without hæmo rhage , prostration was extreme, reactions to painf stimuli feeble or absent, blood-pressures were half norm or less, respiration scarcely perceptible In all h experiments, injection of a small quantity of potassiu phosphate (equivalent to 3–4 mg of potassium) cause the pathological manifestations of shock to disappea completely , blood-pressure rose to normal within 30 sec and respiratory rhythm and normal reactivity an excitability of the animal were restored Introductio of the drug into the subarachnoid space by lumbar o thoracic puncture was without effect however In som experiments where the blood-volume had been reduce to half normal by bleeding, introduction of potassiu phosphate into the ventricles was sufficient to bring th animal out of the state of shock without the necessity o compensating for the blood loss In control cases the

Absorption —It is of interest to compare the output of xalate with the intake According to Cook (1933) mmon foods such as potatoes and cabbage contain -40 mg per 100 g , while rhubarb contains 210 mg per 0 g and spinach 320 mg per 100 g It is evident that ry little of the dietary oxalate normally appears in the ine, as the persistence of oxalate in the urine on an xalate-free diet or in starvation bears witness It is nerally thought that calcium oxalate is poorly absorbed d that its absorption is facilitated by the solvent action f the hydrochloric acid of the gastric juice , however, uantitative results on the absorption of oxalate under rmal conditions appear to be lacking As a prelimin- ry, it was demonstrated in human subjects that the rinary excretion of oxalate is constant over a period of veral days when diet is constant

Thus subject 1 excreted 31 2, 31 4 and 30 1 mg of xalate on the third, fourth and fifth day of a five-day eriod on a standard diet Similar figures for subject 5 ere 31 8, 30 3 and 32 4 mg In an experiment on sub- ct 1, 90 mg of oxalic acid in the form of sodium oxalate as taken daily for three days The oxalate was ingested ith the mixture of milk and water consumed at meal- me and is to be regarded as calcium oxalate Of 270 g of oxalic acid ingested during this period only 9 2 g was excreted in the urine

A similar experiment was conducted on a cat During 2 hree-day control periods the cat was fed on a diet of bread and ilk flavoured with 'Marmite,' but received no oxalate , the mounts of oxalate excreted were 14 and 9 6 mg During the ext three days the cat was fed as before and also given a total f 108 mg of oxalate (36 mg of sodium oxalate in 20 c cm of ilk daily by stomach-tube) 11 mg of oxalate was excreted n the 4th three day period the cat was starved and given 108 g of oxalate (36 mg in 20 c cm of water daily) and excretion ose to 33 3 mg In the final three day period the cat was tarved and given no oxalate , excretion fell to 10 9 mg

Experiments with rhubarb —Further experiments were arried out on human subjects 1 and 2 to investigate the bsorption of oxalate when a meal containing rhubarb as consumed Changes were made only in the main meal of the day, the remainder of the diet being constant and low in oxalate With subject 1 the daily output of oxalate rose from 32 7 to 59 3 mg when rhubarb but no milk was taken with a meal consisting of potatoes, meat and sprouts (table II) When a similar meal containing rhubarb was accompanied by ½ pint of milk, reconstituted from milk powder, the oxalate excretion remained within normal limits In a similar experiment with subject 2 the meal consisted of meat, potatoes and carrots When rhubarb was taken with this meal a value of 67 9 mg was obtained for the urinary oxalate compared with a value of 31 1 mg when ½ pint of fresh milk accompanied a similar meal on a subsequent day A further experiment was carried out on subject 2 in which 0 4 g of calcium as calcium chloride was consumed with the rhubarb , again the oxalate excretion remained within normal limits The rhubarb used in these experiments was of the "forced " or early type and was stewed with sugar in the usual way The figures in table II refer to the weight of uncooked rhubarb

TABLE II—EFFECT OF MILK AND CALCIUM ON EXCRETION OF OXALATE

	,, 18	Potatoes, 8 oz , carrots 5 oz , meat, 2 oz , rhubarb, 5 oz water	49 1

DISCUSSION

It appears from these experiments that the absorption and excretion of oxalate is greatly diminished when milk or calcium is taken with rhubarb Evidently, oxalate is only absorbed in significant quantity when it is present in the intestine in the soluble form A foodstuff such as rhubarb which contains a large excess of soluble oxalate may evidently cause the onset of a temporary but heavy oxaluria unless sufficient calcium is present in the intestine to precipitate the oxalate as the almost insoluble calcium salt Milk appears to be the ideal source of calcium for this purpose, since it is usual to take milk in various forms at mealtimes In addition, the buffering power of the milk may be of some importance, since calcium oxalate is unlikely to be redissolved in the stomach unless the pH of the stomach contents is low While one would expect the oxalate to be reprecipitated as the calcium salt in the intestine it is conceivable that when the acid chyme is neutralised some oxalate may not be immediately precipitated as calcium oxalate if substances capable of hindering this precipitation are present It is evident that the absorption of oxalate is closely connected with the quantity of calcium in the intestine *It has already been demonstrated that the* absorption *of calcium* is *related to the oxalate* content of food Thus Fincke and Sherman (1935) attributed the poor absorption by rats of the calcium in spinach to the presence of oxalate More recently Speirs (1939) showed that not only was the calcium of spinach poorly absorbed but that when it was taken with milk the availability of the calcium of the milk was diminished The above results on the absorption of oxalate are in agreement with these findings It is logical to suggest that a meal containing much soluble oxalate should be accompanied by milk in some form In this way the absorption of oxalate would be cut to a minimum and the tendency to alimentary oxaluria avoided, while at the same time the intestine would be assured of an uninterrupted supply of available calcium

SUMMARY

A group of 14 normal people (10 men, 4 women) living on an uncontrolled diet excreted 20–47 mg of oxalate a day (average 33 mg) On a constant diet the excretion of oxalate in 2 subjects was found to remain steady over several days

Soluble oxalate given by mouth to a cat on a diet containing milk did not raise the output of oxalate , but the same dose given while the cat was starving raised it considerably

In 2 human subjects a meal containing rhubarb raised the output of oxalate to double the normal figure, whereas if milk or calcium chloride was taken with the meal the output did not materially increase

At least part of the oxalate absorbed from the intestine is excreted by the kidneys, and if present in large quantities may favour the formation of stones Calcium precipitates oxalate in the intestine and thus prevents its absorption

It is recommended that milk should be taken with rhubarb and spinach, which are rich in oxalates, in order to avoid excessive oxalate absorption

I wish to thank Prof E C Dodds for suggestions and criticism, Mr P C Williams, BSc, for help with the animal experiments, and those members of the staff of the Courtauld Institute who acted as subjects in the experiments

Lease-Lend —The following pharmaceutical products have been imported from the United States under the Lease Lend arrangement and will shortly be available for distribution amidopyrine, barbitone, benzocaine, pancreatin USP, peptone USP IX, phenazone, phenobarbitone, phenobarbitone soluble, pot guaiacol sulphonate, theophylline, urethane carbromal, pepsin 1/10,000

The nucleus always lies close to the visceral pleura, and in a constant position in the right lung Its site in the adult male is 6 cm from the midline in the 2nd right intercostal space, in women it lies at 5 5 cm and in children at 4 5 cm from the midline in the same intercostal space The regularity of the site is remarkable, and it permits accurate puncture even when radiological localisation is unsuccessful

TECHNIQUE

The patient is given calcium for three days before operation, and receives a hypodermic injection of morphia shortly before the actual puncture The site of the lesion is checked from the X-ray films or is marked out from the measurements given above After careful preparation of the skin a needle 5–6 cm long and 1–2 mm in diameter is inserted perpendicularly to the surface to a depth where it just traverses the pleura and enters lung To those experienced in artificial pneumothorax work there is no difficulty in recognising the entry of the needle into the pulmonary tissue

Calcium should also be given in the postoperative period

RESULTS

The operation is not dangerous and is usually well tolerated Patients do however complain, within a few hours, of slight shortness of breath, shivering and pain radiating through the chest from the point of puncture Sometimes the temperature is slightly raised for a day or so and there may be slight staining of the sputum In only 2 patients was a pneumothorax noted and in both the symptoms disappeared with the withdrawal of air next day Provided the patient is not in an advanced stage of the disease the effects of the puncture are surprising appetite and weight both improve, while temperature, sweating and sputum all tend to decrease The changes are most notable in the milder types of phthisis Exudative lesions tend to resolve and there seems to be no risk of dissemination of the disease In the absence of an obvious-ulcero-cavernous focus healing is rapid in 60–70% of the cases treated, judged by disappearance of tubercle bacilli from the sputum Changes in the sedimentation-rate and in the hæmogram appear quickly and run parallel with the detoxication and general improvement in the patient's condition

In the grosser forms of cavitated disease beneficial changes are not so apparent, though there is some resolution in the affected areas and cavities seem to clear up over a period of months Even in this type of case I think the healing trend is quicker than with other methods of treatment, and 40–50% successful results may be claimed Hæmoptysis occurs in a good many cases and is regarded as marking the onset of fibrosis before it reaches the cicatricial stage Cavities up to 3–4 cm in diameter diminish appreciably in size and may even close, though a second or even a third puncture may be used with advantage if improvement does not seem to be being maintained The interval between punctures should be well over a month In oldstanding sclerotic cavities I use cavernoscopy in order to cauterise the draining bronchus, about 4–5 months after the nucleus puncture (Lavalle 1941) Large apical cavities with adherent pleural layers do not often alter greatly in size and require thoracoplasty for their closure

The improvement in tuberculous lesions in other parts of the body after puncture is comparable to that seen in the lung Larynx, bowel, glands and joints benefit to about the same extent as the actual pulmonary lesions In combined lung and bone-joint forms of tuberculosis I find that only 20% of cases treated by lung puncture improve, but if in addition the nucleus in the diseased bone is locally treated along similar lines the successful cases reach 75% The more severe forms of joint disease, particularly tumor albus of the knee, only respond to the local bone puncture which I have described elsewhere[3]

I should like to emphasise that puncture of the lung is relatively easy to perform, and is harmless to the patient If the beneficial effects of the original puncture are not maintained the procedure can be repeated and in any case it should be done after any attack of intercurrent infection, such as influenza One puncture is sufficient, however, in most cases

SUMMARY

Puncture of the "nucleus of post-allergic has proved beneficial in 60–70% of cases of tuberculosis without cavitation and in 40–50% with cavities

The nucleus occupies a constant position in second right intercostal space It can sometimes identified radiographically, but is often blurred by ment of the lung tissue

Puncture is harmless and is easy to perform It now been used in over a thousand cases

ABSORPTION AND EXCRETION OF OXALATE

J F BARRETT, B SC LOND

(*Courtauld Institute of Biochemistry, the Middlesex h*

CLINICAL interest in the metabolism of oxalic oxalates is focused on the presence of calcium oxal stones and on the occurrence of crystals of oxalate in the urine Such crystals are often viewed suspicion, since it is possible that they may lead to development of calculi containing calcium Commonly but not invariably crystals of calcium are found in the urine after eating foodstuffs rich oxalate, notably rhubarb and spinach Rhubarb especially, is occupying a more prominent position diet of the nation under present conditions, and the spring and summer is extensively used as a substitute for fruit It therefore seemed to be of interest to investigate the factors influencing the absorption and excretion of oxalate

In spite of many investigations carried out in the on this subject, no clear picture has been owing to the difficulties of accurately determining in urine Thus as late as 1931 Cerecedo, having a fivefold increase in the urinary oxalate in one ment, stated that owing to the inaccuracies of the methods in use at that time the inclusion of this result was not justified. In the next year, Dodds and Gallimore (1932) introduced a method for the determination of oxalate which though laborious yielded accurate and reproducible results This method in a slightly modified form has been used in the determinations which The more recent procedure of Heikel and Koch (193 embodies the routine addition of extra oxalate to urine in order to obtain a suitable precipitate of calci oxalate The dubious nature of this operation reflected in the considerable fluctuation in the daily put of oxalate in their subjects The conclusions require confirmation under strictly normal con and with a more reliable method

INVESTIGATION

Normal output —The normal daily output of oxalic in the urine is usually given in textbooks as 15–20 mg although some determinations by Widmark (1937) gave the normal range as 14–56 mg in the case of medical students The results obtained with 14 normal people of various ages and of both sexes are given in table I A range of 20–47 5 mg per day was obtained with an average excretion of 33 6 mg This investigation was conducted during the winter and spring of 1941 and the diet of the subjects was unrestricted The effect of diet was shown subject 5, whose output rose to 67 mg per day when a containing rhubarb and spinach was eaten Subject ate spinach regularly when obtainable It is that the normal output of oxalate is higher than generally supposed

CONTROL OF VENEREAL DISEASE

HE chief medical officer to the Ministry of Health o be congratulated on the tact and persistence he shown in securing the withdrawal of the taboo on mention of venereal disease on the radio and in the ly press His opponents had a certain case, for parents want to have their young children's iosity aroused about this topic, and it is they and the BBC lecturers or the newspaper editors who ve to parry awkward questions But the case for blicity is far stronger even from the point of view the family group, which suffers more than anyone ough ignorance of the dangers of infection Sir LSON JAMESON had to call attention to a rise in own civilian infections of syphilis from 5000 in 1939 5600 in 1940 and 7300 in 1941 If Service infections are added the rise is 70% and a parallel increase gonorrhœa would probably be revealed if the figures uld be ascertained He estimated that there were arly 70,000 new venereal infections last year, not a rprising figure for a nation of 45 000,000, subject the disruptions and strains of war, but in a preventle group of grave diseases just 70,000 too many

The first reaction of the press to its new-found eedom was a series of leaders full of valuable informaon for the public, but containing also some rather ive assumptions The writers seemed happily naware that their papers had been the last stronghold f an obsolete tradition and that the real pioneers in reaking down the policy of secrecy are now dead of ld age or on the verge of a dignified retirement he National Council for Combating Venereal Diseases now the British Social Hygiene Council) was formed 1916 and from that date onwards thousands of ctures have been given to every variety of audience nd masses of informative literature have been istributed Even in 1919 the Church Congress at eicester had a full and frank discussion on venereal isease and its moral and social implications, in which he then Archbishop of Canterbury took a leading art The 200 free clinics to which the chief medical fficer drew attention could not have flourished ithout strong local support That the demand for nlightenment has already spread very far is shown by he results of a Gallup poll published in the *News hronicle* of Sept 16 The interviewers found that 3% of men and 76% of women were in favour of ublic bureaus for giving more information on enereal disease What help is newspaper or BBC ublicity likely to give towards solving the problem ? t should certainly arouse flagging interest and bring nfected persons more quickly to the clinics or to their wn doctors Indeed, one of the most useful ways in hich the daily press could assist is by publishing articulars of local clinics in its advertisement lumns, side by side with those of the Ministry of abour or the Ministry of Food In regard to preveníon however, it is not clear that publicity can do uch more than has already been done, unless more [illegible] on the dangers of promiscuity and the [illegible] g a high standard of sex behaviour [illegible]. The chief medical officer pointed out quite rightly that he spoke only as a doctor and could only lay the medical facts before the public But knowledge of medical facts is not the end but only the beginning of wisdom There is no medical question in which the medical and moral aspects are more closely interlocked than in this one The value of the whole campaign depends on the extent to which leaders of public opinion are ready to take up the challenge the doctors have thrown out A further consequence of enhanced public interest has already emerged in a renewed demand for some form of compulsion. Notoriously the country is prepared to *tolerate, as never before, invasions of personal freedom* provided they are for the common good The Gallup poll elicited the curious fact that, of the sample of the general public questioned, 64% were actually prepared to support a law requiring tests before marriage, though few of them could have thought about the question before it was put to them The Ministry of Health is no doubt keeping its ear to the ground and will take advantage of any public demand for useful measures

It is clear, however, that many technical complications unguessed by lay enthusiasts will have to be considered Does the incidence of marital transmission of syphilis by spouses infectious at the time of marriage justify the vast trouble, expense and unpleasantness of mass blood tests for every prospective bride and bridegroom ? Are experts agreed as to what they would do with the results of such tests when obtained ? It is hard to see how compulsory treatment could be applied without notification, but is compulsory notification of gonorrhœa practicable in view of the difficulties of diagnosing the disease in women and of assessing cure ? Moreover, with the quick results of modern drugs it is not going to be easy to persuade all doctors to notify the unwilling patient whose straightforward and early gonorrhœa can almost certainly be cleared up in a few days Many cases of gonorrhœa, too, will not even consult a doctor now because they have no severe symptoms, and they would be much less likely to do so if the disease were notifiable, and it is the case of mild gleet that is particularly likely to spread infection Probably the best immediate return will be got from the compulsory control of known contacts who have infected others, provided for under a new Defence Regulation (see p 589) These people, whether male or female, will deserve little sympathy for any inconvenience they suffer, and the knowledge that such a measure exists will be a deterrent to the careless and selfish Yet the opportunities of the present time may not recur, and we must not waste them on half-measures If these diseases are to be overcome we must make the most of the cases which do seek treatment by examining every contact of every case The Services use what is in effect notification and compulsion—if a serving woman is infected by a serving man and can identify him, then he is examined, and vice versa It seems illogical under present conditions to apply this fundamental measure to one section of the population and not to all Whole-hearted propaganda can convince the public that these are diseases which must be controlled, and controlled now, if the authorities agree that this can only be done through notification and compulsory treatment they will not find public opinion immovable provided the preliminary bombardment is adequate

Reviews of Books

Epilepsy and Cerebral Localisation

A Study of the Mechanism, Treatment, and Prevention of Epileptic Seizures WILDER PENFIELD, MD Johns Hopkins, DSc Oxfd, professor of neurology and neurosurgery, McGill University, director of the Montreal Neurological Institute, THEODORE C ERICKSON, MD Minnesota, associate professor of surgery, University of Wisconsin London Bailliere, Tindall and Cox Pp 623 44*s*

DR Penfield and his colleagues begin this important book by saying that originally it was their firm intention to deal with focal epilepsy and to elaborate those aspects of it which interested them "with no thought of encyclopedic treatment" Unable to resist the encyclopædic e, however, they have satisfied it by inadequate ence to the rest of the huge subject with results h are ill-balanced and almost dangerous The book cked with original material derived from scrupulous ervation and faultless technique, but the preoccupa- ion of the authors with experimental surgery leads them to present epilepsy as a disease resulting from hosts of discrete lesions of varied pathology As far as they are concerned the local lesion is the thing epilepsy depending somehow on a biophysical or biochemical disorder and often inherited has an insignificant place in the book It would have been better to omit the major subject of essential epilepsy altogether and to have presented a treatise on focal epilepsy None the less, a long chapter by Dr Jasper on electro-encephalography is one of the best reviews of the subject so far published, and a study of the psychology of epileptic patients by Dr Hanover-Erickson is informative and balanced As a survey of the anatomy and surgery of convulsive disorders the book is unequalled

Surgery of Modern Warfare

(2nd ed.) Editor HAMILTON BAILEY, FRCS Edinburgh E and S Livingstone Vol II Pp 1000 40*s*

THE second volume completes the new edition of this comprehensive book on war surgery The articles on burns and on chemotherapy deserve special praise, the work on which they are based has been done in this war rather than the last, and they stand out by reason of their compactness and their satisfactory answers to many obvious questions Some of the advice given on anæsthesia is disappointing Surely the advantages of gas-oxygen and the disadvantages of ether in badly wounded patients need not be learned all over again after the work of Marshall and his colleagues in the last war And why should it be suggested that the anæsthetist in the battle zone must carry on without gas and oxygen cylinders? It is discouraging, too, to see Mr Jenner Verrall defending the guillotine amputation in a book intended as a guide to all the many who will have to do surgery under war conditions Where continuous after-care is assured no doubt it has advantages, but in the last war its use caused needless suffering when the care was broken by long-distance transport Illustrations are good and ample, and the companion volumes will be welcomed by war surgeons

A Descriptive Atlas of Radiographs

(5th ed) A P BERTWISTLE, MB Leeds, FRCSE London Henry Kimpton Pp 584 42*s*

A RADIOGRAPHIC atlas is a useful book for students and practitioners but to be effective it should contain first-class reproductions of common diseases and the diagnosis in every case should be fully established Some of Mr Bertwistle's radiograms are good, some are bad and many are indifferent There are cases in which the diagnosis is doubtful and some in which the diagnosis is wrong Thus a typical Charcot arthropathy of the lumbar spine is diagnosed as osteoarthritis (fig 269) "A deformed gall-bladder" (fig 553) is a common normal variation, and "an adhesion to the gall-bladder" (fig 555) is a Phrygian cap deformity Some pictures of gall-stones are printed wrong way round Under the heading "normal chest" (fig 695) the author makes the remarkable assertion that "the markings of the bronchial tree are beautifully seen, the older view that these markings are due to blood-vessels can be definitely discountenanced" Many of the reproductions in the gastro-intestinal section are poor, but the sections on normal bones, fractures and renal diseases are satisfactory The first edition of this atlas appeared in 1926 and it is obvious that many of the radiograms antedate that year Thus neither the technical nor the medical advances in radiology during the last 16 years are properly represented

Edinburgh Post-Graduate Lectures in Medicine

Vol II, 1940–41 By various authors Edinburgh Oliver and Boyd Pp 536 12*s* 6*d*

MOST of these Honyman Gillespie lectures have already received notice in our columns A reminder from F E Jardine of the value of clinical inspection is timely and salutary in these days of hasty recourse to special methods of investigation D M Dunlop's lecture on medical dietetics abounds in shrewd sense, and GP's who see the end-results of both medical and surgical treatment will wholeheartedly endorse the opinion that peptic ulcer is best treated by bodily rest and mental peace W F Harvey pleads for a simplification and a more extended use of blood-examinations and Charles Cameron discusses modern methods of treating pulmonary tuberculosis In the surgical field, W A Cochrane surveys the present position of orthopædics, Sir James Fraser of wound infection and accidental wounds, and W Mercer of fractures of the neck of the femur In his interesting account of the treatment of war wounds in France during May and June, 1940, J S Jeffrey points out that local applications of sulphonamide produce a concentration 80 times greater than when the drug is given by the mouth The diagnostic and therapeutic possibilities of tracheobronchoscopy and œsophagoscopy are considered by G Ewart Martin, and of special interest to those concerned with the care of evacuees is G H Percival's lecture on war and skin disease The volume ends with an informing and thoughtful lecture by R J S McDowall on the physiological approach to medical problems

Neuroanatomy

FRED A METTLER, MD, professor of anatomy, University of Georgia school of medicine London Henry Kimpton Pp 476 37*s* 6*d*

THIS book has been well planned to give the anatomical background needed in the study of clinical neurology It is accurate, orderly and devoid of ambiguity, the style is crisp and the nomenclature logical and consistent The 337 illustrations are all original and include reproductions of many novel dissections and unusual pictures of structures in the central nervous system Line diagrams in colour are never used to simplify but always to elucidate, and have been introduced to good effect, those representing the meningeal structures of the base, and the relationship of nuclear masses in the brain stem, are specially helpful The text is not interrupted by references but there is a full bibliography The author has been imaginative in meeting the advanced student's needs

Parents Revolt

RICHARD and KATHLEEN TITMUSS London Secker and Warburg Pp 128 3*s* 6*d*

THIS book, which has a foreword by Mrs Sidney Webb, is an examination with statistics of the causes leading to the limitation of families in England The limitation is now so great, the authors find, that the one-child family has come to be the thing and families of four or five are looked on as unwieldy and eccentric England as a power needs a large population, no doubt, but it is open at least to philosophic question whether England as a happy community needs more than the land can support, so that not everyone will immediately share the alar They tra and despondency of the writers of this boo vidualist the cause of shrinking families to the indi an average acquisitive nature of our society, but acquisitive cted has presumably been rampant since man owned a th and herds, and to denounce it will not put such a sens community values into English- and American-speak peoples as to restrain them from race suicide Nevert less, their indignation is stimulating, and their statist though they overload the book, provide starting-poi for informed discussion of a topic which affects the wh race truction of the fœtal vessels to the placenta ey do not accept that a patient has a true toxæmia less they can demonstrate "toxic" infarcts or scular diseases in the placenta The predisposing tor to the obstruction of the placental vessels is a osition of cholesterol under the endothelium In attempt to prevent this deposition, they administ ed thyroid in doses of gr 1½–3 daily to women tinuously from the third to the eighth month of gnancy, the incidence of toxæmia in these women nained the same as in a series of controls They n tried iodine in the form of 'Lipoiodine,' with a se of gr 1¼ iodine daily, throughout the same iod This fairly definitely reduced the incidence mild toxæmia, and possibly of the severer forms of æmia also though the figures are too small to stantiate this conclusion How this effect was ained is not clear, for the theoretical basis for the rk would lead one to expect a similar effect from yroid Nevertheless the results are sufficiently hope- l to warrant investigation on an adequate scale

These explanations of pregnancy toxæmia as a ult of placental infarction are supported by a con- lerable weight of evidence and probably represent advance towards the eventual solution It is a mulating mental exercise to try to account, on each tory in turn, for the different incidences of toxæmia hydatid mole, erythroblastosis fœtalis, plural gnancy, postmaturity, chorionepithelioma, parti- y separated placenta prævia, and retention of the centa for several days after delivery

DEFENSIVE SECRECY

The Duke of Wellington told Mrs Norton that, Chancellor of Oxford University, he was "much posed to authors" In their humbler sphere edical practitioners and hospitals are much exposed lawyers Whether as a counterblast to an un- elcome claim for professional fees or because cilities for treatment are too hopefully regarded as guarantee of cure, disgruntled patients or their xt of kin launch legal proceedings which are a otorious distraction of medical practice Legal oceedings must be met with legal aid "Say as ttle as possible," advise the defending lawyers, admit nothing" The teaching is doubtless sage ough Civil expressions of sympathy will be isted into confessions of carelessness A casual mark about a sheer accident will sound sinister hen repeated forensically in the opening speech of laintiff's counsel On the other hand, if it be not oo weak and too sententious to suggest it, are there o dangers in defensive secrecy? An overworked or nder-experienced nurse uses the wrong bottle, or repares the wrong solution of a dangerous drug, a ifficult and perhaps necessarily hurried diagnosis is t fault, or some other regrettable contingency occurs oyalty among colleagues and hospital staffs rallies ound If the patient pulls through, neither he or he nor the next of kin need be any the wiser Mean- while a precautionary silence is maintained But here is another side—the side from which the tients or their anxious relatives will be looking hen information withheld has at last been dragged ut by the coroner, confidence in the medical pro- ession and the hospital system will be jeopardised

A simple instance may illustrate our point, let it be given as a hypothetical case A patient aged 74 is taken by her daughter to hospital in a feeble condition The plinth normally used in the receiving department happens to be occupied because a child, accompanied by her mother, is awaiting examination The elderly patient is placed on an emergency table and her daughter is asked to withdraw Two hours later, and with no word said about an accident, the daughter sees the mother again and is shocked to find her face cut and bruised, nobody will disclose what has happened The daughter's husband calls at night in vain Twelve hours after the patient's death, and a day and a half after the accident, the family is told for the first time of her having fallen from the table in the receiving ward The details are elicited at the inquest There should have been at least two nurses in the ward, but a temporary cause had reduced the staff there to one student nurse The latter had done her best, standing between the two tables, to keep an eye both on the child and on the elderly patient, but, while the doctor was speaking to the child's mother, a bump was heard The 74-year-old woman had rolled off the emergency table, which turns out to have been just an operating table, perhaps twenty inches wide The medical evidence attributes death to hypostatic pneumonia (following immobilisation in bed), senility, myocarditis and arteriosclerosis The coroner makes his comments He knows that hospitals are short-handed, he knows that this particular hospital is in general admirably administered There, however, are the ineluctable facts The feelings of the relatives, baulked in their natural and proper desire for information, can be imagined A verdict of "death by misadventure," to which the coroner adds an expression of sympathy with the relatives, exonerates all concerned from the immediate implications of legal liability But there may well be an enlargement of the circle of folk outside who next time will wonder, almost suspiciously, what goes on behind those hospital doors, and why a patient's closest relations are denied their right to be told when something untoward has occurred

PLATELETS AND THROMBOSIS

Having shown how to measure the stickiness of platelets,[1] Wright has now applied her technique to a study of the changes after normal labour and after surgical operations,[2] since these are times when venous thrombosis is particularly liable to occur She found that parallel to the rise and fall of the platelet count there is a rise and fall in the stickiness of the platelets as measured by their disappearance from a heparinised sample of blood rotated in a glass bulb The greatest stickiness and the highest counts are found about the tenth day, after which there is a slow return to normal, taking about another ten days Simultaneous observations of the red cell sedimentation-rate showed that the changes had a different periodicity —a maximum increase about the fourth day—and consequently Wright concludes that plasma factors were not responsible for the changing stickiness of the platelets Her opinion is that large numbers of new platelets are released from the bone marrow in response to the stimulus of trauma and loss of blood, and it is these young forms that cause the excess stickiness All this goes to show that we must not concentrate too much on plasma factors in our efforts to avoid postoperative thrombosis, especially as the period of maximum platelet stickiness is also the period of greatest liability to thrombosis

LUNG PUNCTURE IN THERAPY

Much if not all of our treatment of pulmonary tuberculosis remains empirical, or is directed towards purely mechanical ends, and the essential problems underlying susceptibility and resistance remain unsolved Progress in the last fifty years has been marked by such milestones as the introduction of sanatorium regime, artificial pneumothorax and the other ingenious and determined developments of collapse therapy, the rise and fall of gold therapy and more recently the introduction of cavity drainage Each of these has enlarged the scope of available treatment, but the clinician, ably directed by the radiologist and abetted by the surgeon, has tended to focus much of his attention on the pulmonary lesion and to lean somewhat heavily on Providence in the matter of that humoral response which inevitably will determine the ultimate fate of his patient In his paper on another page Lavalle, of Buenos Aires, invites phthisiologists to adopt an ingenious operative procedure which, although directed to a focus in the lung, yet, he claims, exerts a beneficial influence on the whole defence mechanism both local and general He holds that puncture of a certain area of lung with a needle is followed by a degree of improvement that is beyond all reasonable expectation in the exudative stages of the disease His claims for improvement in ulcerative or cavernous forms are more reserved, but even then the healing tendency appears to run a more favourable course and assists any necessary surgical intervention

Houghton[1] has lately drawn attention to the improvement that sometimes follows trauma to the lung in the drainage of tuberculous cavities, even when actual drainage of the cavity is not established, the lung has simply been punctured by a fine trocar and cannula But the basis of Lavalle's operation lies in the puncture of a definite area—the "nucleus of postallergic focal infection" This nucleus is said to lie with remarkable constancy just under the lung deep to the second right interspace in front, and its existence should readily be confirmed or disproved by pathologists What happens when this nucleus is punctured is conjectural Lavalle suggests that there is a freeing of antigens or antibodies from the focus, and that this produces a rise in local and general resistance Alternatively some of the effect may be brought about by an entirely non-specific action from local trauma of the tissues Trauma elsewhere (in the skin, for example) is known to modify the reactivity to other stimuli, with the release of histamine like bodies What, for instance, underlay the remote effects of the seton which were so long unquestioned? There seems to be little difference in the local effect produced by trauma and by certain organic or inorganic substances It will be recalled, moreover, that non-specific shock therapy has been advocated in the treatment of pulmonary tuberculosis and that a variety of antigens have been used A well-known empirical effect of trauma is seen when tuberculous peritonitis is treated by laparotomy, often to the great benefit of the patient Bone and joint tuberculosis has similarly been subjected to trauma by Lavalle and others with advantage in a number of cases Such explanations of the observed phenomena are, however, purely speculative

The simplicity of the puncture operation is at same time an encouragement and a disadvan Uncontrolled enthusiasm before there has confirmation of results may bring the procedure disrepute before its value and place in treatment be assessed But its novel principle cannot discarded without trial in view of the results claim for it

TOXÆMIA AND PLACENTAL ISCHÆMI

It is nearly thirty years since Young first pounded his theory that placental ischæmia is origin of the toxæmias of pregnancy During time the theory has received much lip service has not been investigated at all thoroughly by o workers. It has achieved a place in the textb side by side with the dozen other theories, perhaps because of these evil associations, per merely as a result of age, has lapsed graduall partial oblivion Now Young[1] has jerked the th back into the full glare of attention Its basis rem the same, but it is supported by so many new f that it must be given full consideration in any mo study of the toxæmias and will certainly stimu research

Young's primary thesis is that certain wo have an "abortion taint" which is possibly endoc in origin and reveals itself by interference with maternal circulation to small or large areas of placenta In the early stages of pregnancy causes abortion, in the later stages it causes place necrosis or retroplacental hæmorrhage This t shows a strong tendency to recur in successive p nancies, and in any pregnancy may result in an these three manifestations The more serious c sequences arise when the maternal circulation part of the placenta is disturbed in late pregna This part undergoes necrobiotic changes which not be recognisable in the first day or two, even hi logically, but subsequently go through the var stages of infarction Even in its early stages necrosing tissue produces substances which ca albuminuric toxæmia, a large necrosis gives ris pre eclampsia or eclampsia There is however essential condition for this effect the fœtal circ tion must continue Too large a placental les such as one involving over half the organ, kills fœtus and prevents the development of the toxæn Accidental hæmorrhage is the other serious manife tion of the abortion taint in late pregnancy Hæn rhage takes place behind a part of the placenta, w is thus cut off from the maternal circulation If blood can escape externally the placental damag usually small and there is little resultant toxæn If the bleeding is concealed a greater amount placenta is separated and toxæmia follows in t thirds of cases If the hæmorrhage is so severe t the fœtus is killed, toxæmia does not follow, tho there may be a subsequent azotæmia similar in so ways to that seen in the crush syndrome Col Bartholomew and Grimes[2] agree that placen necrosis is responsible for the toxæmias of pregnan and that the severity of the toxæmia depends on mass of the infarction But they differ from You in maintaining that the infarction is caused truction of the fœtal vessels to the placenta y do not accept that a patient has a true toxæmia ss they can demonstrate "toxic" infarcts or cular diseases in the placenta The predisposing or to the obstruction of the placental vessels is a osition of cholesterol under the endothelium In attempt to prevent this deposition, they adminis- d thyroid in doses of gr 1½–3 daily to women tinuously from the third to the eighth month of gnancy, the incidence of toxæmia in these women ained the same as in a series of controls They n tried iodine in the form of 'Lipoiodine,' with a e of gr 1⅓ iodine daily, throughout the same iod This fairly definitely reduced the incidence mild toxæmia, and possibly of the severer forms of æmia also though the figures are too small to stantiate this conclusion How this effect was ained is not clear, for the theoretical basis for the rk would lead one to expect a similar effect from roid Nevertheless the results are sufficiently hope- to warrant investigation on an adequate scale

Annotations

PROF LINA STERN

BESIDES conducting research the Institute of Physiology at the Second Moscow State Medical Institute trains teachers and research workers, many of those who studied there now hold chairs and lectureships in laboratories throughout the Soviet Union Prof Lina Stern, whose paper on shock appears on another page, is director of the institute Her own interest in research dates from 1902 when she was a student at the University of Geneva, there, working in the laboratory of Prévost she began by studying internal secretions of the liver Her MD thesis, written in 1903, was a physiological study of ureteric contraction, and was awarded a university prize She became an assistant in Provost's laboratory in 1904, and her work as a teacher and scientist was increasingly notable from that time onward In 1906 she was accredited lecturer at Geneva, and in 1917 was appointed to the chair of physiological chemistry In 1925, with a considerable European reputation, she left Geneva to share in social reconstruction in Soviet Russia She founded her own school of physiologists, which has made a study of tissue barriers, particularly the blood brain barrier, oxidation in animal tissues, the influence of metabolites on various physiological systems, the relations between central and peripheral sympathetic and parasympathetic centres, and the effect of high-voltage currents in animals Since war broke out she has been engaged on physiological problems which have immediate application, among which is her method, now described, of directly influencing nerve centres in cases of shock She has fought hard for the freedom of women, and many of her women students now hold important research posts In 1939 she was elected the only woman member of the Academy of Sciences of the USSR

RADIUM FOR UTERINE HÆMORRHAGE

SINCE the early work of the French gynæcologists in 1906–07 radium has been successfully used in various forms of uterine hæmorrhage Although its hæmostatic action is not understood systematic work has put dosage on a proper basis A survey of the Medical Research Council reports *Medical Uses of Radium* shows that for a time a wide difference of opinion existed as to the best dosage for a given set of clinical conditions, but since 1933 data from the Royal Free Hospital and the Marie Curie Hospital have confirmed the view that an exposure *to 50 mg of radium for 22–24 hours can be looked on* as a maximum need for uterine hæmorrhage Curiously enough while the interstitial radium treatment of cancer started with strong doses which gradually diminished as experience grew, the opposite tendency was taking place in the cases of uterine hæmorrhage, for much of the early work by Oudin, Verchere and Wickham was carried out with 50 or 100 mg of radium, the exposures being for an hour or so repeated very cautiously at intervals A further step was the recognition that the appropriate dose of radiation depends on the age of the patient, and in Elizabeth Hurdon's *Cancer of the Uterus* the fullest information on technique, dosage and results are given In an analysis of 837 cases under observation for 1 to 10 years up to the end of 1935, 97% of the menopausal cases and 78 5% of the younger patients have remained well without further treatment A recent unpublished report from the Marie Curie Hospital implies that radon has proved a complete substitute for radium in the treatment of uterine conditions Here the exposures seldom exceed 24 hours, and there is little difficulty in adjusting quantities so that the same dose results Russ and Scott [1] have shown that in the destructive action on the ovary of the rabbit radon can replace radium over quite a wide range in the quantities and times of sure Radon however is not a good substitute for when, as in breast cancer, exposure may continue week on end, the decay of radon cannot in such a safely be made good by increasing the radon the needles, because the higher intensity is not tolerated by normal tissues

VIRUS INFECTIONS OF THE MAMMALIAN

WHEN Rous and Murphy[1] used the developing embryo for the cultivation of Rous sarcoma they not have realised the potentialities of the field they opened up Hardly a week goes by but the embryo its membranes are found to have new use in the study the growth of viruses, bacteria, spirochætes, fungi protozoa Goodpasture was one of the first to seize the possibilities of the method and has continued adapt it to more and more problems Viruses actively growing cells in which to multiply and emb tissues seem to be the most suitable for this pur All viruses are not able to infect avian embryonic but may grow in the embryonic tissue of other su hosts, such as *mouse embryo or guineapig e* Recently Sanders and Jungeblut [2] found that the m strain of SK poliomyelitis virus grew best in t cultures of embryonic mouse brain, reaching a titre 10^{-8} in the 6th culture generation, but also grew cultures of embryonic guineapig brain, reaching a titre 10^{-4} Non-nervous mouse embryonic tissue was found capable of maintaining a certain basic level virus growth but was greatly inferior to the cultures central nervous system tissues The embryonic tissue was found quite unsuitable The growth of viruses in embryonic tissues has greatly facilitated advance of knowledge of virus and rickettsial dise For their volume these tissues often yield many times quantity of infective agent previously available other sources for use as antigen for complement fixation and as vaccine for immunisation The infective agents may remain highly virulent and have to be inactivated, as in rickettsiases, while in yellow fever and vaccinia virus becomes attenuated during passage in these Though these chick tissues have been used for years it was only recently that Berge and Hargett pointed out that protein of 14 day chick embryos, in contrast to that of 10 day embryos, is highly anaphy lactogenic for young guineapigs This probably explains the severe reactions obtained with the equine encephalomyelitis vaccines made from the older embryos, in contrast to the slight or absent reactions from the yellow fever vaccine Poleff [4] and Findlay and MacCallum [5] used minced human placental tissues in suspended cell cultures for the growth of vaccinia and yellow fever virus Now Goodpasture [6] has advanced further by the ingenious method of grafting human fœtal membranes, chorion or amnion or both at once, on the chorioallantoic membranes of the developing chick embryo The tissues were placed mesodermal surface uppermost and were apparently nourished by plasmatic circulation Satisfactory infection was obtained by applying a paste of virus containing tissue to the graft 24–48 hours after grafting Using this technique grafts of human amnion were readily infected with the viruses of herpes simplex, variola, vaccinia and the virus of mare abortion, the last of these had not hitherto been propagated beyond doubt in the tissues of an alien species Human chorion was very resistant to all the viruses used This would explain the comparatively few cases of intra-uterine infection from infected mothers with such very contagious diseases as measles, mumps, chicken pox and influenza, though a number of infections with small-pox have occurred Wolf and others[7] have reported a case of prenatal inception of infantile toxoplasmosis, perhaps the chorion will be a good medium for growth of these organisms The experiments of Anderson and Goodpasture have also thrown light on the mechanism of immunity in some virus diseases, for they found that skin from a chicken hyperimmune to fowl-pox was readily infected with the virus when grafted on the chorioallantoic membrane of the developing hen's egg but again became refractory when grafted on the immune fowl A similar set of events occurred with skin from humans immune to cutaneous vaccinia, suggesting that in these diseases at least immunity depends on the antibody in the fluids bathing the tissues For some unexplained reasons many animals which are susceptible in the embryo to various viruses are resistant during the first few weeks of life, and some which are susceptible in the first few weeks gradually become more resistant with age though active growth of tissue is occurring The new technique of Goodpasture and his colleagues may make it possible to study specific resistance and susceptibility in a way that is impracticable in the intact host

"THE DOCTORS MAYO"

In a full scale biography of the Mayos, father and sons, and an authoritative history of the Mayo Clinic Miss Helen Clapesattle has written an absorbing story[8] She is of the University of Minnesota to which the Mayo Clinic is affiliated, and she is to be congratulated on the historical accuracy of her record and the way in which she has handled that part of the story which concerns clinic staff now living Those who know the clinic intimately will find little fault with the results of her patient research, except that the wealth of the documentary evidence tends to slow up the swing of the story and make the book over long William Worrall Mayo, born in Eccles near Manchester, in 1819, migrated to the United States in 1845 He practised medicine as a pioneer physician in Minnesota against the primitive background of covered wagons, Indian insurrections, civil war and the rapid agricultural development of a frontier state He died in 1911, but not before he had seen his two sons William and Charles rise to medical eminence and international fame in the very village in which the father practised The main body of the book concerns the medical odyssey of these two remarkable men and the living memorial which they created The Mayo Clinic has probably exerted a more profound influence on American medicine and perhaps on world medicine than any other single factor How it was built and why it developed in a frontier village of Minnesota is told At a time when group medicine is being actively discussed this book presents a statement of its ideals, underlying principles and end-results Those who knew Dr Will and Dr Charlie personally will put the book down with admiration for its scholarship, but with the feeling that a shorter, more pungent biography is still possible, drawing a little more warmly two of the most remarkable characters, medical or otherwise, who have passed across the contemporary American scene

OPHTHALMIC BOGIES

H M Traquair[9] has made a collection of popular misconceptions concerning the eyes, some of which many medical men share with their patients Foremost of these is the question "Does over use cause disease of the eye?" The answer is an emphatic No The eye is a part of the body and subject to the same ills, and so one finds eye disease occurring chiefly as a result of such complaints as diabetes, nephritis, hypertension and toxæmia from whatever cause Disease of the eye will no more result from over-use than disease of the brain from too much thinking, or disease of the ear from too much listening At the same time, too much eye work will cause tired eyes, for which the cure is to rest them The term "eyestrain" has come to stay, but we do not speak of brain strain or ear strain No-one is surprised if their legs are tired at the end of the day, but all resent it if their eyes are weary The question then arises, "How much will glasses relieve eyestrain?" If there is an appreciable error of refraction this should be corrected in office and precision workers But even when this is done many will experience eye fatigue at the end of the day It is usually found in these patients that it is not the effort of accommodation that causes fatigue but the effort of convergence, and relief will come to them when their muscles—including internal recti—have an increased tone, whether this be brought about by exercises, holiday or both To supply these patients with convex magnifying glasses unless they are presbyopic, is to worsen their lot for the accommodation is thereby somewhat relieved but the effort of convergence required is greater than before

PHYSIOLOGY OF THE PREMATURE INFANT

CERTAIN physiological adjustments are usually successfully made by the newborn baby as he passes from a parasitic to an independent existence The immaturity of the prematurely born infant however, renders him less successful at such adjustments, and Levine and Gordon[1] of New York have discussed the physiological handicaps of the premature infant, leading logically to a consideration[2] of what can be done clinically to smooth the path Premature infants show respiratory difficulties which predispose them to asphyxial attacks and aspiration pneumonia Circulatory difficulties are indicated by cyanosis of the extremities and frequent œdema Faulty control of body temperature facilitates their well known tendency to alarming bouts of low and high temperature A diminished tolerance of the alimentary tract predisposes to gastro intestinal attacks Other problems include the increased fragility of the capillaries impairment of renal function, inadequate antenatal storage of minerals and vitamins, defective hæmopoiesis, immaturity of liver function and incomplete development of enzyme systems This formidable list is analysed by Levine and Gordon in some detail For example, the immaturity of the *respiratory system* can be shown to be related to at least five special problems The respiratory centre in the premature has a high threshold for all stimuli, nervous and chemical, the centre is relatively poorly vascularised, a sparsity of elastic tissue in the lungs delays full pulmonary expansion, the muscular and skeletal structures are weak and soft so that intrathoracic negative pressure is poor, and finally there is the persistence of a fœtal type of hæmoglobin which may not take up oxygen so well in the lungs as the normal adult type The erratic control of temperature in the premature infant is also shown to be due to various inter related factors First there is a low total heat production due to bodily inactivity and feeble muscular development Next a surface area out of proportion to the body-weight and a paucity of insulating subcutaneous fat permit excessive loss of heat by radiation and convection Finally Levine and Gordon show that the immaturity of the sweating mechanism leads to a breakdown of this means of compensating for exposure to heat The renal function of the premature infant has recently been studied by Young, Hallum and McCance[3], there is clear evidence of impaired urea clearance Of immediate practical importance is the physiological immaturity of the alimentary system It is shown that there are heightened demands for relatively large quantities of food, and yet enzyme activity, swallowing and sucking reflexes, and a faulty absorption of fat all exist to add to the difficulties Fat splitting is essentially normal but absorption is defective Further evidence of inefficient digestion is shown by studies on amino acid metabolism With a relatively high protein diet the premature infant tends to excrete certain intermediary metabolites of aromatic amino acids A striking discovery is that administration of vitamin C, in single or divided doses of 100–500 mg of ascorbic acid leads to a prompt rectification of this metabolic aberration and the disappearance of the abnormal metabolites from the urine This action of vitamin C is specific, and other substances chosen (vitamins A and D, riboflavin and others) were without effect This consideration and many others arising from the review by Levine and Gordon lead to certain valuable practical measures General aids for the handicapped premature start with an antepartum programme of diet, hygiene and general care Specific measures include procedures which tend to minimise the severity of such potentially impending symptoms as asphyxia, hæmorrhages, anæmia, birth trauma, hypothermia and infections The incidence of cyanotic attacks may be reduced by abstaining from the use of narcotics and analgesics shortly before and at delivery, by adequate resuscitative measures and the use of oxygen when indicated Skilled medical and nursing supervision are essential and stress is laid on proper feeding A low fat diet with relatively high carbohydrate and protein—digestion of the latter aided by vitamin C—is advocated together with relatively low fluid intakes A daily intake of 120 calories per kg is claimed to give optimal growth Great care over the post hospital regime of the premature baby is also important to complete the programme of his physiological adjustment

RATCATCHERS' RIDDLE

SEAFARING rats go roving, whether the world is at peace or war, and dockside rats are hardy parents of big families In the port of London an old feud between man and rodent has lately taken a new turn For many years the dock authorities and their tenants the shipping companies have destroyed rats and mice, but unsystematically, without that nice attention to choice of bait and type of trap which raises ratcatching to the status of a science Six-monthly inspection and fumigation of foreign going ships was established as an international practice in 1926 and the danger of spreading plague has thus been much reduced, but rats as carriers have a list of diseases to their discredit as long as their tails, and any live-and-let-live policy towards them would be fatal in the long run to the party which intended to do the living There were fears, at the outbreak of war, that if bombing broke open warehouses, and ratcatchers went to other fronts rats might go from strength to strength , these have not been wholly fulfilled, for though the rodent population of ships has increased the land-rats do not seem to have made full use of the opportunities offered by bombing to rodents of resource and sagacity The port health authority and the port of London authority have laid their heads together to make sure that things shall get better rather than worse Dr M T Morgan, port medical officer of health, and Mr James Fisher and Mr J S Watson, from the Bureau of Animal Population at Oxford, state[1] that the health authority has taken over all responsibility for rodent destruction while the port of London authority defrays the cost The scheme covers all the premises belonging to the port and also the premises of tenants and the craft of shipowners who choose to share in it by paying a subscription A staff of nine rodent officers carries out the work, and the bureau has collaborated and advised The Seamen's Hospital has lent laboratory accommodation

Some odd facts have been learned about rodents since the scheme has been running Thus the old English black rat, who came over at the time of the Crusades, prefers to die for the sake of boiled shrimps, used as bait in a breakback trap , whereas mice fancy rolled oats Brown rats can be put down conveniently by mass poisoning, a method to which the black rat fails to respond , and mice can rear naked families in a nest of frozen kidneys in a refrigerating chamber at 17° F of frost In the six months that the scheme has been running only 26% of premises have been visited by a single rat, and only 15% by a mouse or mice as judged on the evidence of droppings and the use of runs These are good figures, but the area within the jurisdiction of the port authorities is only a small part of the frontage of wharves, docks, basins, embankment and river side, and from the river densely populated industrial areas spread inland Thus the authorities are set about with good harbourage for rats, and even though they clear their own territory completely must be alert for fresh invasions There is much to be done before docks, premises and craft are cleared , and meanwhile it remains for London planning authorities to make homes in the dock region more appropriate for men and less attractive to rats

MINIMISING OXALURIA

IT has been known for very many years that the urine contains oxalates, and that, owing to the insoluble properties of their calcium salts, these are often in crystalline form and readily conglomerate into stones The oxalates excreted by the kidney seem to be derived from two sources, the internal metabolism of the body and the food We can do nothing at present to modify the former, but we know that certain foods, such as rhubarb, spinach and strawberries are very rich in soluble oxalates and that their ingestion often leads to a shower of oxalate crystals in the urine Indeed, the limitation of their consumption by people with stones in their urinary tracts is an old medical custom Most of us however like strawberries, and some of us are fond of rhubarb, and it is worrying to think that we may be ruining our urinary tracts by eating a little stewed rhubarb in the spring As so often happens, the solution of this difficulty has been the work of many people, most of them not even interested in oxaluria The studies of calcium absorption which have been made in the last fifteen years have clearly shown that anything which precipitates calcium tends to prevent its absorption if taken at the same time Phosphates, phytates[1] and oxalates[2] have all been demonstrated to have this effect Barrett, in the work reported on another page, has now established by experiment that the converse is also true Milk or calcium salts, taken with soluble oxalates, prevent the absorption of the latter so that no increase in oxaluria ensues This discovery rings true, for it is the local application of well-established principles So children may have their strawberries, and we may all enjoy our poached eggs on spinach, and our rhubarb tart, without a twinge of foreboding—provided we take plenty of milk with them

SIR NORMAN WALKER died on Saturday last, at Balerno, after a long illness He succeeded Sir Donald MacAlister as president of the General Medical Council in 1931, and retired from the presidency in 1939, but retained till last year the seat which he had held as Scotland's direct representative since 1906 He was in his 81st year

A CONFERENCE ON INJURIES

AT the invitation of the Director-General of Medical Services of the Ministry of Pensions, a conference of surgeons was held at Queen Mary's Hospital, Roehampton, on Sept. 23 and 24, Mr. G. R. GIRDLESTONE presiding.

Mr. T. P. KILNER demonstrated plastic and orthopædic cases. Arguing that the best dressing for a large open wound is skin, he suggested that all surgeons in charge of accident services should be given special equipment for cutting large Thiersch grafts of selected thickness. He demonstrated cases illustrating the use of thick Thiersch, tubular, and flap grafts. Mr. GEORGE PERKINS showed a patient with the moderate but disabling degree of equino-varus that is associated with the relative weakness of the external popliteal group of muscles after a partial sciatic recovery. These patients are much benefited by an inside iron, outside T-strap, and a toe-raising spring attached to the outer side of the sole opposite but not distal to the 5th metatarsal head. He then illustrated by a number of patients his ardent and infectious faith that it is the use, as natural as possible, of the muscles surrounding the fracture, which stimulates and accelerates union. He limits the extent of his plaster splints to the margin of safety. He dislikes the Bohler iron and the single stick, but likes a heel and toe movement with particular attention to the active use of the toes. He prefers crutches or two sticks with limited splinting to a long plaster which makes full weight-bearing safe, and even goes so far as to recommend that splints can be discarded, at least during the waking hours, on evidence provided by palpation and before there is radiographic evidence of union.

In the afternoon Prof. R. J. WILLAN discussed *failures after operation for derangement of the knee-joint*. He stressed the value of an exact history, and the far greater value of the evidence which could be elicited by X-ray examination as well as by clinical examination. Once again it was made clear that the diagnosis of an internal derangement, indicating the removal of a semilunar cartilage, requires great care and consideration. If this is true in civil life, decision to operate on a soldier or a pensioner requires even more deliberate judgment. The vital necessity for a thorough reconditioning was emphasised.

Mr. A. G. ORD spoke on the treatment of *minor fractures*, which he thinks are often kept in plaster too long. In his own clinic he finds periods of splintage safe which others might think dangerously short. The principle again emerged that it is the man and his team, rather than the method, which makes for success.

Prof. T. P. MCMURRAY discussed *non-union of fractures*, with special reference to the scaphoid of the wrist. In his opinion non-union of the scaphoid results from missing the diagnosis, or—though not so often—from a failure to reduce a displacement. It is wrong, he said, to suppose that the fractured scaphoid was almost always just a crack without displacement. Those in which there was displacement and which were not reduced would be less likely to unite, and more likely to give rise to a secondary arthritis. A practical test of deformity can be applied gently and slowly when the case was first seen after the accident; in the absence of post-traumatic swelling, if there was no deformity a full range of movement could be accomplished, whereas the presence of deformity would limit movement. He advocated carrying the plaster to the tip of the thumb; the position of the wrist should not be dorsiflexion, but neutral. Bone-grafting in his opinion should only be used in cases of delayed union in the presence of perfect reduction; it is a mistake, he thinks, to graft a scaphoid where there is malposition of the fragments, whether or not secondary osteoarthritis has already developed. In late ununited wrist fractures the bone may appear as if it were congenitally bipartite, but this condition will not, per se, be responsible for pain or for disability. The joint may possibly be a little more sensitive to a sprain, but after X ray has disclosed the old fracture the injury should be treated as a sprain and nothing more. On the other hand arthritis may have developed and a sprain or continued occupational strain may aggravate and so call attention to the arthritis. In the presence, then, of arthritis with non-union, bone-grafting is absolutely contra-indicated. If the disability is sufficiently severe the scaphoid should, in his opinion, be removed. He admitted that reported results have not been good, but thought that this was possibly due to traumatic methods of scooping out the scaphoid. He preferred a gentle if tedious dissection with scalpel and forceps. He admitted that the power of the hand was afterwards less than normal but the hand could be more freely used than in the presence of radioscaphoid arthritis. After this operation the joint should be kept at rest for 6 weeks, after which active movement should be gradually resumed.

In the discussion which followed some advocated arthrodesis for the secondary radioscaphoid osteoarthritis, as well as the excision of the proximal row of carpal bones.

Mr. C. GORDON IRWIN gave a cinematograph demonstration on *late surgery for disability of the hand* after gunshot wounds or septic infection. Where an old infection had flared up, he favoured delayed incision and active movements throughout. Provocative massage is advisable before doing a plastic operation, on account of the danger of flare-up. For Dupuytren's contracture, he thinks excision and grafting better than tenotomy. For stiff fingers, the position of the bones when fractured is immaterial, but the motor apparatus is important. He had never succeeded in restoring movement in stiff fingers by any form of surgery. Amputation of a finger is justified if it interferes with the patient's working capacity, but amputation of the hand is done too often, he considers, and the loss of a hand is a tragedy. He had performed several successful cineplastic amputations but the limb-fitters had never been able to fit a suitable prosthesis. Repair of extensor tendons is usually successful; repair of flexor tendons gives poor results. In amputation of the finger the head of the metacarpal should be left, since function is more important than a cosmetic result. He had not seen painful stumps after finger amputation except when there was a question of compensation or pension. Excision of nerve bulbs is never successful in abolishing the tenderness, he finds, and correction of malunited phalanges by ostectomy gives bad results. Fingers should not be splinted for longer than 7–10 days, and the thumb should not be held in the plane of the hand but abducted and splinted at right angles to the plane of the hand. He was not in favour of doing plastic reconstruction of fingers.—Mr. KILNER emphasised that for crippled hands prevention was better than cure. After seeing burns treated in many hospitals he was a strong supporter of the Bunyan method, and in particular he advocated the first-aid Bunyan bag, filled with sulphonamide. The important things in the treatment of burns were the early control of infection and the early removal of necrotic tissue so that the raw area could be covered with a skin graft at the earliest possible moment. The best dressing for a raw surface area was transplanted skin. Early movement of the fingers is important—another argument in favour of the use of the Bunyan bag. The nursing difficulties are greatly lessened, he finds, when the Bunyan bag is used because the patient can be moved painlessly. In treating burnt hands, the forearm should be slung. Resting the hand on a pillow encourages deformity. In Dupuytren's contracture, and in burns, the important question is: has skin been lost? If so it should be replaced by a graft. He wondered whether any operation on fixed finger joints was worth while, and he thought that the value of cineplastic amputations should be reinvestigated.

Mr. G. H. STEVENSON thought shortage of material would prevent the wide application of the Bunyan bag treatment. A short arm bag would be economical, and electrolytic sodium hypochlorite could be manufactured in hospital. He was not satisfied that the ideal first-aid treatment for a burn had yet been found, but thought we might go back to an oily solution. He had had good results by grafting skin on the end of a denuded terminal phalanx, but not much success in repairing flexor tendons in the hand. He was strongly opposed to the treatment of hand and finger injuries in a septic casualty department. All patients with these injuries should be admitted; they ranked in urgency with fractured femurs. Surgeon Rear-Admiral G. GORDON-TAYLOR said many burns had been treated by tanning. It was not generally realised how many patients had at times to be given their first treatment by one doctor who, perforce, chose the quickest and simplest treatment He deprecated the modern view that cut tendons should not be immediately sutured —Mr IRWIN in reply said he had himself had the two flexor tendons of the index finger sutured two weeks after they had been cut The result was excellent He always used to advocate immediate suture of cut tendons, but after reviewing his cases he decided to suture later , and his results since had greatly improved He advocated the Bunyan bag as first-aid treatment Lengthening fingers with bone grafts covered with grafted skin was rarely worth attempting because a finger was very little use unless it possessed delicate sensitivity In repairing tendons he had successfully grafted extensor tendons, but had failed with flexor tendons

MEDICINE AND THE LAW

Mistaken Diagnosis of Pregnancy

ENTERING judgment in Megarry *v* Vernon on the basis of an agreed settlement, Mr Justice Norman Birkett observed that, if he had any sympathy in the case, it was equally divided Miss Megarry, aged 44, had offered her services to the WAAF and, during medical examination, had been told that she had a fibroid growth She was advised that a good gynæcologist could remove it and that she could then offer her services again She went into hospital, taking with her a note from her panel doctor and another from the WAAF doctors The experienced surgeon who prepared to operate found, on opening the abdomen, what looked like a typical pregnant uterus After consulting his colleagues, he closed the abdomen without completing the operation It is by no means unknown to him (as to others) that women desirous of terminating an unwanted pregnancy sometimes exploit a surgeon by having an operation in such circumstances as these He told the patient next day of his conclusion She indignantly denied the allegation Later there was an interview with the patient's brother, a medical practitioner, at which the surgeon repeated his view that the patient was 4½ months pregnant in spite of her denials Further examination and a first and second Friedman test showed that the diagnosis was mistaken The surgeon expressed his regrets to the patient for his error, but, not unnaturally, he failed to conciliate her He had attacked her chastity, and she sued him for damages both for negligence in his diagnosis and for slander of a most serious kind The defendant denied the negligence and the slander and, in respect of the latter, pleaded privilege

At the trial Miss Megarry gave evidence bearing out her claim She said she asked the surgeon to record his mistake in writing, but he refused Expert evidence followed on her behalf Next morning, after the defendant surgeon had been in the witness-box for an hour, and before his colleagues and his own medical experts had been heard, the plaintiff's advisers initiated a settlement which was obviously a proper ending to the case The court was thus deprived of an interesting argument on the issue of privilege wherein it would seem that the defendant should have succeeded On the issue of negligence in diagnosis plaintiff's counsel had insisted that it was perfectly easy, when the abdomen was opened, for a surgeon to detect whether he was dealing with a fibroid or a pregnancy The defendant's case was that he made no examination *per vaginam* because this is not the common practice with an unmarried woman He did not feel justified in taking the uterus out of the abdominal cavity for more detailed examination because this would have meant a larger incision and possible disturbance to the supposed pregnancy He was evidently until his mistake was established, convinced of the correctness of his diagnosis , this involved the assumption of wilful deceit and the danger of his being made a party to an illegal operation

Diagnosis of pregnancy is not so absolutely certain a matter as patients may suppose Both the Aschheim-Zondek test and the Friedman test have their margin of error, however small Even with X-ray examination the radiogram may be misread or may not disclose the true condition The uncertainty is all the more reason for not telling a patient definitely that she is pregnant unless she has admitted the fact , it is wiser to regard case as one of mere suspicion Doubtless the defen in the recent unfortunate case would now be ready to acknowledge that he committed not only a mistake his professional judgment but also an indiscretion in firmness with which he maintained his mistaken His experience may be of value to others in a position

In England Now

A Running Commentary by Peripatetic Correspondents

I WELL remember my disappointment when Eddington first made his pronouncement that, for the one home of life in the Universe, Nature had scattered a million useless barren stars in space I had always hoped that life might be more widely spread than that The universe seemed hardly worth running if so little of it could house life , for human reason almost demands that life is the only thing for which it is worth while to run a universe at all But the depression produced by reading Eddington was as nothing to the utter hopelessness engendered by Jeans , for Jeans has declared that the home of life in the universe is as " a millionth part of a grain of sand out of all the sea-sand in the world " Yet, in the end, it was Jeans who cured my depression , for his statement was so dramatic that it made me think I began to recall the endless miles of sandy beaches on which I had roamed in various parts of the world, and I thought how wonderful it was that Jeans, who had never even seen all these and the thousand more besides, should have any definite idea how much sea-sand there was in the whole world And on this a great assurance came to me, for I realised that, in truth, he had no idea at all It is quite beyond the bounds of possibility that any human being, no matter how clever he may be, could give even the roughest approximation of an estimate of how much sea-sand there is in the world I am quite sure Jeans could not even pretend to make a guess at it The statement, I concluded, carries no more authority than would be implied in the dictum of the gardener's boy as to the number of blades of grass there were in the world What then is the use of dragging in " a millionth part of a grain " as though the matter were being dealt with by methods of great mathematical precision? After considering these things I became as the savage who, having accepted the story of Jonah and the whale as a sacred verity when it was taught to him by the missionary, was subsequently instructed in the doctrine of the immaculate conception This he was quite unable to believe and, after thinking the matter over, said to the missionary " If that woman had been my wife I would have killed her , I don't believe it , and, now I come to think of it, I don't believe the story of the big fish either " Frankly, the " millionth part of a grain of sand out of all the sea-sand in the world " story has made me bold to say that I don't believe it and that I don't believe the " one in a million " story either To my great relief, it is now possible to fall back on the more recent dictum of the president of the British Astronomical Association that, by the law of probability, " amid the vastness of the universe life is widely diffused " This, in itself, is a welcome relief, but for my present line of thought there is more interest in the matter than that conveyed in these comfortable words Dr Davidson sees in Mars a place " where conditions prevail that will probably prevail in thousands of millions of years from now on our Earth, when most of the atmosphere will have disappeared and probably most of the animal life " Evidently Mars has been through its troubles, life is passing into a steady decline and the only possibility is that, though " there is no reason why vegetable life should not exist," animal life has passed On Earth our troubles are with us there is no need to remind anyone of that But things are very different with Venus " In hundreds of millions of years from now it is possible that Venus will be the abode of higher forms of life, though it is impossible to say whether their development will resemble that which took place on the Earth " Venus has all its troubles ahead and they lie well in the future There have been many who have thought it would be a great achievement of science if we could one day communicate with Mars I have no interest whatever in the possibility of imunicating with Mars. Whatever form they may have taken its troubles are all done with. But I certainly think that someone should try to communicate with Venus. Anyhow we *do* know what has happened to us on Earth. We can all realise the disaster that occurred when evolution took the foolish turning that ended in the emergence of man from a decent "lower mammal." Someone should warn Venus before it is too late. We do not want a beautiful planet like that to be ruined if we can avoid it. It is surely enough that we should ruin our own.

* * *

It has been my good fortune to sail in all sorts of craft, ranging in size from half deckers to large schooners. I have cruised, I have raced but always there has been something missing. Something which now that I have at last attained it, has made me realise that R. M. Ballantyne was not entirely in the realms of phantasy when writing of coral beaches fringed with palms and sapphire blue seas on which schooners made their way.

All this from having to visit British Honduras. This country lacks adequate communications though active measures are now being taken to improve them and of necessity much of the traffic is carried on the rivers or along the coastal waters sheltered by a fringe of islands called cays. These cays which are typical tropical islands, range in area from a few acres to a square mile or so. One trip down the coast scheduled for me would normally be made in a motor boat a hot and often smelly journey occupying a considerable part of a day and the same on the return journey but my host, whose kindness and originality I can never praise enough, arranged a passage for us in the handsome schooner of about twenty tons belonging to a well-known naturalist. Never has any excursion steamer left Tower Pier with a more light-hearted ship's company than did ours on the brilliant early morning we left Belize. The vessel had a crew of three Bay Islanders. Originally these islanders were British colonists along part of what is now the Honduras Republic. Now citizens of that country, they remain British in outlook and English is their language.

On a spinner over the counter we caught fish of a size that more than answered the fisherman's prayer. I can recommend for luncheon grilled kabala steaks the colour reminiscent of salmon and the flavour well! Inhabitants of most British territories bordering the Caribbean have, tragically enough, to eat salt fish imported from the North American coast rather than the fresh food provided on the spot. Our work ashore completed left us with an hour or two of light to reach the cay where we planned to spend the night, and we lazed between the islands steering by the appearance of the white sea bottom, many feet below us, easily seen through the gin-clear water. Finally, we arrived at our anchorage and were all quickly over the ship's side to bathe in the Caribbean, which if once sampled, spoils you completely for bathing anywhere else in the world. An idle evening was spent on deck under the bright tropical sky, our only regret being the deteriorating news of the Japanese advance towards Singapore. The wireless-set may or may not have been a boon that night, but it did at least tell us the worst. It was a crime to go to sleep, but the effects of a day such as had passed could not be delayed. We settled down to eight hours of the best.

With full daylight it was possible to take stock of our surroundings in greater detail than on the previous evening. The schooner lay in a bay about a quarter of a mile from the shore sheltered on the weather side by small cays. Ashore could be seen some of the few inhabitants moving around their lotus island while we on board wished the clock would stand still so that we could relax and enjoy the golden hours. But there was more work to be done, so after another exotic bathe and breakfast it was up-anchor and away.

* * *

The ripening of the apples in my garden was the signal for a more than usually severe outbreak of petty larceny; for in addition to the usual small boy to whom stolen fruit tastes sweetest the more dangerous type of thief who steals to sell in the black market has invaded my privacy. The worst feature of the work of these scoundrels is that having dared their youthful acquaintances to accompany them into forbidden territory at the first alarm their cry is "Devil tak' the hindmost." The result is that the relatively innocent smaller boys are caught while the real criminals by virtue of their superior agility escape the retribution which should justly befall them. There have, however, been so many raids on my orchard of late that it has become necessary in the interests of my fruit trees, if for no other reason to make an example of the first available scapegoats. Two wretches who invaded the sacred precincts last night were misguided enough to climb too high in the tree to make a timely retreat and instead attempted to hide in the upper branches. When spotted they apparently appreciated the hopelessness of their position and surrendered promptly. According to the best traditions of the Force I began my examination by asking for names and addresses. Without a moment's hesitation the younger of the two ragamuffins gave my own name and indicated an abode in a nefarious quarter of the town. I told him that he was little credit to a good name but as I could not persuade him to alter it, had to pass over his offence for the time being. The other scamp found some difficulty in deciding whether he was called Robert or Bobby but as it proved later that his real name was William he had cause enough for uncertainty. There had been a third rascal with them, so they said whose name was extremely appropriate; he was called Robbing and like Judas of old had had the bag which was half full of fruit when he absconded leaving them to face the music. From their willingness to give information about him I suspect that they knew that he had left them to their fate without doing much to help them. Some further inquiry revealed that one of our two captives was a hardened sinner. He admitted a previous conviction for "selling" wood as he called it, without thinking it necessary to tell me that theft of the wood was a necessary preliminary to its sale. When asked why he thought I had taken him into custody and why I would presently turn him over to the police he said that he had been "eating" apples. I suppose such an evasive turn of mind indicates that the child is psychologically abnormal but the theft of a few apples scarcely seem to justify his incarceration in Broadmoor as a criminal lunatic. In due course a sergeant and a constable arrived a notebook was produced and in it were entered the particulars which I had elicited, together with my own name, address occupation and to my annoyance, my age. I often used to wonder why every report of court proceedings ran on this wise, "John Smith (59) of 19 Apple Row, Orchardston, a seedmaker by occupation, was charged with stealing sugar." It is plain to me now. No policeman worth his salt regards the description of one of his fellows be he witness prisoner or mere suspect as complete without all those particulars. I, however dislike publicity to be given to the fact that I am entitled to an old age pension and consider that as a gesture to public opinion the ages of all parties involved in prosecution might well be given. The press report already quoted would then read, "At Rhimie High Court today, before Sheriff Whalley (99) of 'The Weasles,' Stotley, John Smith (59) of 19 Apple Row Orchardston, was charged with stealing sugar. Constable A. McNabbem (67½) of the local police force *deponed* that ..."

Our youthful criminals answered with creditable self possession the sergeant's questions, and mercifully neither burst into tears during the examination. By some mischance the booty which I had forced the scamps to disgorge was lying close by on a side table where it caught the eye of the youthful budding Sherlock Holmes who accompanied the sergeant and before I realised what was happening it had been impounded as evidence and, in addition, I had to give them my wife's last brown paper bag in which to remove it. It appears that these two miscreants will appear in court in about six weeks time. As I have never known these apples to keep for more than a month after being pulled from the tree I tremble to think what horrid sticky mess will be produced from that paper bag on the dies iræ. It appears too that I may have to lose a morning's work to give the evidence which will secure the conviction of my two scapegoats. The price which I am being asked to pay for a little peace is heavy, and it would have been far less trouble to turn them over to their own parents for correction.

That article on lid-retraction in the *Lancet* of Oct 3 intrigued me What is this state of staring anxious surprise? Surely it is a defence mechanism Not only is the visual field increased—at least mine is—and its periphery more illuminated, but it is also the most delicate method of detecting the direction of the wind If you go out of doors, especially on a cold day, and stare violently the windward part of your recently uncovered conjunctiva smarts, when you face the wind for some reason it doesn't If you watch a boy suddenly smelling wood smoke, his eyes slightly stare, the head rotates and goes backwards, the nostrils dilate and more conjunctiva is uncovered It is the method of getting "centre" to the wind's bowling Why is it important? Because if our noses were half as efficient as those of the fathers of our phylum or our fox-terrier's, of whose turbinates I am reminded every time I eat a cake of shredded wheat, we should know what was moving within a hundred yards of us upwind What's more, binaural directional hearing cannot function properly unless the error of the wind is obviated by facing it Anyone who has watched dogs hunting or deer feeding, to take examples from our brother mammals only, will realise the overriding importance of the wind to them The nose is the enemy, food, water, path and mate detector, especially at night, and the uncovered conjunctiva is its invaluable assistant I know a lot of people snort at this sort of thing They remind me of a nouveau riche O no, I was never a slightly unscrupulous manager A scheming clerk? Don't be silly A nasty little office-boy? Ridiculous! I was always as I am now, big, prosperous, pot-bellied, smelling of cigar smoke, gold chain, powerful, omniscient Yes, staring is a defence mechanism developed probably not so much for individual protection as for tribal protection, for the punishment on the individual would not have been so constant and reforming And it is a nicely graduated mechanism The wide-eyed children need it most and it is correlated in them with better directional hearing (who sees the aeroplane first?), keener smell (a lot of children know their masters and mistresses by smell) and acuter taste ("I can't tell the difference between sugar and saccharin *this* war") The day-dreamer is another who needs some limited measure of its protection Why in Graves's disease the autonomic interprets some internal poison as an external threat, an "alert," just as in asthma, she interprets it as a respiratory invasion, is fairly clear For millions of years those were the common if not the only threats, and she is as much automatic as autonomic ("She" because of her motherliness, contrariness, immunity to argument and sense of humour How she would chuckle at a term like "conditioned reflex")

Modern medicine is so taken up with "how" that it often forgets to ask "why?" We've got to the small boy's pull-the-watch-to-pieces stage, or it's possibly a reaction from the false and facile assumptions in the post-Darwinian period, of which this little essay may not be entirely innocent

---

FACIAL HEMIATROPHY

L Zeno reports a case of facial hemiatrophy successfully treated by means of free fat-grafts (*Ann Cir Argentine*, 1942, 8, 52) A boy of ten years had received a blow on the right side of the face when fighting another child two years before, and atrophy of that side followed The atrophic changes affected chiefly the subcutaneous fatty tissue, but the skin was also involved, with diminished sense of pain and of secretion of sweat and sebum The child's mental state had suffered from the effects of the deformity, he was timid and shrinking and ashamed to show his face to strangers An incision was made in front of the ear, parallel to the posterior border of the ramus of the mandible, and with Mayo's scissors the subcutaneous tissue of the cheek was split so as to form a bed for the graft A second incision in the nasolabial fold enabled a similar bed to be formed in the upper lip, which had to be freed from the underlying muscle in order to bring down the angle to the level of the opposite side Through these two incisions free fat-grafts obtained from the gluteal region were insinuated with forceps The skin wounds were closed and pressure was applied by a plaster cast fixed over the head with a bandage Recovery was uneventful, the cosmetic result was excellent, and the boy's mental state was greatly improved

Letters to the Editor

COMFREY, MAGGOTS AND UREA

SIR,—One of the nurses in a neighbouring village asked me, a fortnight ago, if I knew of anything that would help a poor old woman suffering from a chronic ulcer on her leg I gave her some comfrey (powdered root) wherewith to make a dressing and a little bottle of allantoin wherewith to reinforce it I had a message yesterday informing me that the ulcer is practically healed I am disposed to think that it is best to use the comfrey preparation because, as in others of the simple remedies, the natural allantoin is dextro-rotatory whereas synthetic allantoin may become lævo-rotatory if the crystals are old and have been exposed to the air

Cheltenham CHARLES J MACALISTER

SIR,—Your annotation seems to imply that allantoin in general, and allantoin admixed with sulphanilamide in particular, is of no proven value After an extended trial of the latter, I am opposed to this view The results I have obtained in using it in conjunction with cotton suture and ligature material in nearly 1000 cases compel me not to allow this implication to go unchallenged

Harley Street, W1 HAMILTON BAILEY

COMPLEMENT FIXATION IN TYPHUS FEVER GROUP

SIR,—Your annotation of Oct 10 contains a number of incorrect statements, which should not be allowed to pass unchecked

1 The statement is made that, since the clinical differentiation between typhus and Rocky Mountain spotted fever is very difficult, "the only means of diagnosis in the past has been the inoculation of guineapigs with blood from the patient immediately it has been withdrawn" The foremost expert on Rocky Mountain spotted fever, Dr R R Parker, director of the Rocky Mountain Laboratory, Hamilton, Montana, not long ago defined the position quite differently He says (*J Amer med Ass* 1938, **110**, 1275), "The three tests ordinarily used are the infection test, the Weil Felix reaction and the protection, or virus neutralisation, test" "On the whole the most useful and practical test is the Weil Felix reaction, that is, the test of the patient's serum for agglutinins against O strains of *Proteus X19* and *X2*" The serum of some patients with Rocky Mountain spotted fever reacts only with *Proteus OX2*, or shows a higher agglutinin titre for *OX2* than for *OX19* Either of these results confirms the diagnosis and at the same time excludes that of typhus fever When, on the other hand, the predominant agglutinins are of the *OX19* type, a differential diagnosis as between the two diseases cannot be made Davis and Parker (*Publ Hlth Rep Wash* 1938, 53, 1526) showed that both the *OX19* and the *OX2* antigens are essential components of the O antigen of the rickettsia of Rocky Mountain spotted fever In the annotation, however, the existence of the *Proteus OX2* type is not mentioned

2 Bengtson and Topping (*Amer J publ Hlth*, 1942, 32, 48), whose paper is the subject of the annotation, did not employ *Proteus OX2* antigen in their agglutination tests The "Weil Felix titres" recorded in their tables and figures refer solely to agglutination of *Proteus OX19*, and cannot therefore be accepted as an adequate statement of the agglutinative properties of the sera they tested Nevertheless Bengtson and Topping give a clear account of the relative usefulness and the limitations of the two reactions they employed—namely, complement fixation with typhus rickettsiæ and agglutination with *Proteus OX19* They showed that the complement fixation test is the better criterion of past infection with endemic typhus, whereas the *OX19* reaction is the more useful test in early diagnosis The annotation, however, does not mention the latter fact, and, moreover, it gives an inaccurate summary of the results Bengtson and Topping obtained with the complement fixation test in cases of Rocky Mountain spotted fever Thus a note is made of their table 4 which shows that the sera from 14 cases of Rocky Mountain spotted fever gave no cross fixation with typhus rickettsiæ, but no mention is made of table 5 which shows 8 cases in which there was cross fixation Bengtson and Topping rightly concluded that "the question of the best method for the early diagnosis and the differentiation between typhus and Rocky Mountain spotted fever is one which cannot

be answered completely at the present time " In the annotation, however, Bengtson and Topping are said to have demonstrated that the complement fixation test " will clearly differentiate between endemic typhus and Rocky Mountain spotted fever " Incidentally Bengtson's name is spelt wrongly throughout the annotation

3 Having thus exaggerated the value of the complement-fixation test with rickettsial antigens the annotation proceeds as follows " Though more or less specific for the typhus group of fevers, the Weil Felix reaction being an indirect test has never been happily accepted by many workers These new antigens may give us a simple inexpensive direct test for diagnosing this group of diseases " Your readers may compare this sweeping statement with the following quotation from a review by Zinsser (*Amer J Hyg* 1937, 25, 451), who devoted the last ten years of his life to the study of typhus fever " The so called ' Weil Felix reaction ' has attained extraordinary importance in the diagnosis of typhus fever and considerable significance for the differentiation of the several groups of Rickettsia infection The three most important varieties of proteus bacilli in use at the present time are those known as OX19, OX2 and OXK "

It is well established that the position of the Weil-Felix reaction as a diagnostic test for typhus fever is in some respects better than that of the classical serodiagnostic method—the Widal test in typhoid fever There is, admittedly, still plenty of room for improvement in the serology of the typhus group of fevers Advances may be expected from the adoption of methods similar to those now in use in the serum diagnosis of the enteric fevers These, it is known, are based on the separate estimation of the antibodies that correspond to the different kinds of antigen possessed by typhoid and paratyphoid bacilli Rickettsiæ, too, are complex antigenically (Castaneda and Zia, *J exp Med* 1933, 58, 55) The heat-stable O antigens of rickettsiæ are available in the most convenient form in the three types of *Proteus X* What is needed are suitably prepared reagents for the demonstration of the antibodies to the heat-labile rickettsial antigens These will supplement rather than replace the *Proteus* OX antigens

Emergency Public Health
Laboratory Service A FELIX

*** No-one doubts that the Weil-Felix reaction has been of great value in the past and probably will be in the future, especially in the hands of particular individuals The purpose of the annotation was to stress the desire for and the possibilities of a relatively simple biologically specific reaction for widespread use, which all will agree is to be preferred at any time to a concomitant reaction, one recent example of the non-specificity of the latter being the observation that certain experimental animals inoculated with clean strains of *Spirillum minus* develop agglutinins for the OXK strain of *Proteus* in much higher titre than after infection with *Rickettsia orientalis* —ED L

MECHANISM OF CONVULSIVE THERAPY

SIR,—The originators of insulin therapy and of ' Cardiazol ' or convulsive therapy got their names transposed in your annotation of Oct 31 (p 520), this, of course, was a mere slip of the pen The statement, however, that " convulsive therapy and particularly electric shock " is to be preferred in such and such a psychosis, is open to misinterpretation, since they are one and the same treatment, electrical shock being nothing but a technical modification of Meduna's convulsive therapy He first used camphorated oil for producing the convulsion when introducing it in 1934, and later cardiazol The next technical improvement was the substitution for cardiazol of ' Triazol ' by Walk and Mayer-Gross in 1938, and in the same year Cerletti and Bini replaced injection by electrical stimulation of the cortex These historical facts are not important, but it should be more widely known that the therapeutic effects of this electrical modification, all too easy to carry out with the foolproof apparatus, are in no wise superior to those obtained by cardiazol or triazol, in fact, it is to be feared that ultimately they may prove to be inferior, since their consolidation by means of psychotherapy is becoming neglected, the patients being more and more left to themselves between treatments

Cornwall H PULLAR-STRECKER

RICKETS IN THE BREAST-FED BABY

SIR,—I am glad to see it stressed in your leader of Oct 10 that the pregnant and nursing mother should drink her daily pint of milk and should also have adequate vitamin D Thus sufficient vitamin D should be ensured in her breast milk for baby's needs—surely better than giving the baby some form of vitamin D in addition to his natural food, and thus upsetting the perfect balance of his diet ? Certainly the synthetic form of vitamin D is more desirable than cod-liver oil for obvious digestive reasons If cod-liver oil is used then the Government compound is to be chosen since much less need be given Halibut-liver oil is in the same way suitable since one drop of this, we are told, is equivalent to one teaspoon of pure cod-liver oil in its vitamin content My experience with a good many normal breast-fed babies who have been given the compound (or halibut-liver oil drops) is that slight sickness resulted or the stools became relaxed and perhaps frequent, or that both these conditions occurred On comparing foods available now with those of prewar days, I cannot see that we need seriously lack in any way Our margarine has been reinforced with vitamins equivalent to butter standard, and the ration of this is sufficient Eggs, although today they are less plentiful, have previously been available to most mothers with priority claims Meat has never been considered a good source of vitamin D It seems reasonable that the fats and milk, together with fish-liver oil taken by the average mother, will ensure ample of the antirachitic vitamin in her milk, and her fully breast-fed child should not even now need an extra addition any more than he did before the war

The Nursery World E MORRISON

MASKED HYPERTHYROIDISM

SIR,—Your leading article of Oct 31 is to be welcomed *as a sign that thyrotoxicosis is becoming increasingly* recognised as a mosaic of symptoms, of which hypermetabolism is only one constituent fragment Your observation that we lack any simple means of measuring thyroid function other than by the indirect means of the BMR, indicates a major difficulty both in research and clinical work Far too much attention has been paid to the BMR in the past as an index of severity of, and standard of comparison between, cases of thyrotoxicosis, and most clinicians now rely very little on it The work of Hinton and his associates, which you quote as suggesting a separation between hyperthyroidism and hypermetabolism, is a step in the right direction, and may end a deadlock which has so long existed in investigation of thyrotoxicosis Such a separation would be complementary to the work of Dodds and Robertson (*Lancet*, 1933, ii, 1137 and 1197), who separated hypometabolism from hypothyroidism They raised the BMR of a patient with myxœdema to + 30% by administering dinitro-*o*-cresol, but without relief of symptoms, yet with thyroid extract symptoms were relieved at a BMR of + 10%

It would be a major advance if some substance could be found capable of lowering the BMR in thyrotoxicosis without ameliorating the hyperthyroidism—such as occurs with iodine It is also to be hoped that future researches on thyrotoxicosis will not be concentrated entirely on the thyroid gland, to the neglect of the soil in which the disease flourishes—namely, the constitutional make-up of the patient

Cambridge LAURENCE MARTIN

NICOTINIC ACID FOR ANGINA PECTORIS ?

SIR,—I think we should differentiate between the immediate transitory effects and the lasting effects of nicotinic acid Its immediate effect is to relax spasm As regards the lasting effects, many patients suffering from heart troubles show constipation, defective absorption of nutriment and increased production of indole. C P Rhoads of New York demonstrated that indole impaired the utilisation of vitamin B (*J Amer med Ass* 1939, *113*, 297) whose constituents are components of several enzymes and ferments Nicotinamide, is an important part of co-zymase of von Euler-Chelpin and of Warburg's co-ferment, thiamine pyrophosphorylate is an essential part of co-carboxylase, riboflavin phosphorylate attached to a special protein is the yellow

University of Cambridge

On Oct 31 the degrees of MB, BChir were conferred on R M Stuart Matthews

Association of Anæsthetists of Great Britain and Ireland

The following officers have been elected by this society for the ensuing year president, Lieut -Colonel Ashley Daly, vice president, Dr C F Hadfield, treasurer, Dr Z Mennell, and secretary, Dr A D Marston

Appointments

FOY, HUMPHREY, MRCS, DMRE visiting radiologist to the Robert Jones and Agnes Hunt Orthopædic Hospital, Oswestry

KINNEAR, JOHN, MD ST AND, MRCPE workmen's compensation referee for dermatitis for Cupar, Arbroath, Dunblane, Dundee, Forfar and Perth

Births, Marriages and Deaths

BIRTHS

CARTER —On Oct 25 at Castlederg, co Tyrone, the wife of Surgeon Lieutenant D M F Carter, RNVR—a son

KERSHAW —On Nov 1 at Leamington Spa, the wife of Surgeon-Lieutenant G R Kershaw RNVR—a son

MARSHALL —On Nov 3, at Carshalton, the wife of Dr T S Marshall —a son

MATHIAS —On Nov 4, at Aberystwyth, the wife of Dr J Gordon Mathias—a son

MOORE —On Nov 9, in London, the wife of Mr A M A Moore, FRCS—a daughter

THOMSON —On Oct 27, the wife of Dr E J Thomson, of Grimsby—a son

WILLIAMS —On Nov 4 at Oxford, to Dr Joy Williams (*née* Jewson) wife of Squadron Leader Denis Williams, MD RAFVR—a son

MARRIAGES

BINNING—McKECHNIE —On Nov 7 at Northwood John Sydney Binning, MB, captain RAMC, to Patience Mary McKechnie

COMPSTON—STANDISH —On Nov 7, at St Peter's, Vere Street, Nigel Dean Compston, MRCP to Diana Mary Standish

STRADLING—SNOW —On Oct 31, at Exeter, Peter Stradling, LRCP, to Peggy Snow, LRCP

VERE HODGE—BUDGEN —On Nov 7, in London, Nicholas Vere Hodge, FRCS, squadron leader RAFVR, to Ann Budgen

WALKER—KITWOOD —On Oct 29, at Boston, Lincolnshire, Gerald Walker, MRCS, to Lyndis Margaret Elizabeth Kitwood

DEATHS

BELL —On Nov 3, at Netley, Delvine Bell, MC, MB EDIN, lieut-colonel RAMC of Denewood, Rustington Sussex

GOWLLAND —On Nov 1 at The Star and Garter Home Richmond Edward Lake Gowlland, DSO, TD, MB LOND, lieut colonel RAMC, aged 65

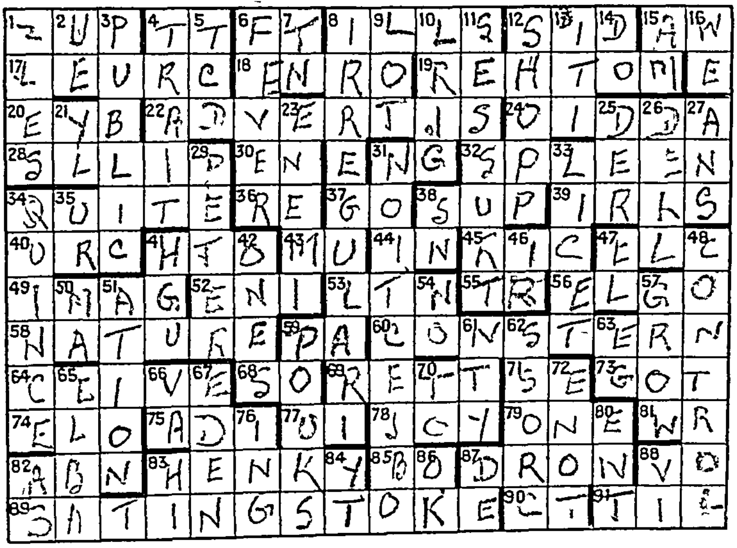
HOGG —On Nov 5 at Poona, William Peat Hogg, MC, MB ABERD, DTM&H lieut colonel IMS

INCE —On Nov 7, at Sturry, Kent, Arthur Godfrey Ince, FRCS

MARTIN —On Nov 1, at Bath, Henry Meredith Martin, M CH DUBL, FRCS

PIRRET —On Nov 1, Mary Janet Pirret, MD GLASG, DPH, of West Cromwell Road, SW5

WALKER —On Nov 7, at Balerno, Sir Norman Walker, MD EDIN, LLD, FRCPE, aged 80



New EMS Hospital in Wales

On Nov 3 the Minister of Health opened the 600 bed Merriston Hospital, near Swansea, which has been built at a cost of £180,000 under the Emergency Hospital Scheme Until heavier emergency demands arise, five wards, with 200 beds, are being placed at the disposal of the Welsh National Memorial Association for tuberculosis cases The hospital will also be used to relieve the pressure on the Swansea and General Eye Hospital

Tuberculosis Association

A meeting of this society will be held at 26, Portland Place, London, W1, on Friday, Nov 20, at 2 45 PM, when Dr Clifford Hoyle, Dr W C Fowler and Mr R C Brock will open a discussion on the treatment of tuberculous pyothorax

LANCET CROSSWORD

SIR,—When (19rev)s of (57/76) (10rev)s meet out (12dn/76) and discuss where the very best (62rev/87ac rev) (1ac rev/1dn) are (70) be (73), (79) is sure to (88ac rev/36rev)hear it said,—" (16) always (37) to Mr (29) (34dn) for ours You can always (36/21rev) (54rev) his to be (34ac) free from all (31dn rev/65rev) (22/76) (15dn rev/69rev) " (49/52rev) the (60/51) in these (45rev/47ac rev)s, (63rev/53rev/36rev) than the (42) you frequent, my (37/14rev) sir, (16/36) I to employ my (43/71) in (38ac rev/83dn/31ac) Tom and Dick's (11rev), (83ac)'s (8dn/84rev) (28rev), or even a *Lancet* (3/51)! What (82ac/63/51) of high principles (18/70rev/87dn rev) in my (58)! How (25rev/74rev/7rev) of commerce! How my (23/71rev) would have triumphed!

Actually Margaret, my (43/71), was so (81/41ac rev) at the slightest (83dn/7rev) that the (59ac/46) of us might accept the (25/37rev/51) that she (15ac rev/26rev) out (54rev) me without as much as " (37/14rev/20rev)," but (43/4ac/36rev/76)—as she always (14/71rev) when (12ac rev/4dn)—, " Oh, (14/7rev) (87dn/64) yourself!" She was a (37/14rev) (70/41dn rev) (43/71)—she came from the (43/71/43rev) at (5)—though " suffering much from (32) and (66/59dn) " and (41ac rev/36rev) similar (8ac) Unfortunately I had had to (89) her rather (17rev/21rev) that very morning because she would (56rev) a (9) of (35rev/87) (82dn)s who shouted (40rev/87dn) remarks on the (12ac rev/59ac/46rev/84rev) in our ages (68) now, thanks to you, sir, I am in the un(30/88dn/65rev) position of having (54) (43/71) It (39) me not a little —to employ a (91rev/70rev/71rev)

As you yourself (47dn rev/7rev) a (87dn/6ac) hand in (87dn rev/13/31ac) this (85ac/86), you cannot very well (36/88dn/16rev) it in your columns A pity, I should have (34ac) (30/78/87dn rev) (81/13/31ac) a (59ac/63rev) or (68) of highly (87dn/47dn rev/90/65rev) prose—and incidentally (30/45/83dn/31ac) the (72rev) of your (3/51), instead of all this (54/38dn rev/30/71) where I have with considerable (76/30/77/84rev) to (44/71/55rev) awkward words, (88dn/87dn 33) " (88dn/87dn 33)," and quotations, (63) " This (41ac rev/36rev) (67), demi-Paradise," without (12ac rev/70/55rev/76) the theme too much, but with (79rev/41dn rev) double-(62rev/76) (55/59ac rev)s to (27rev/36) and delude the poor (85ac/85ac rev)s who fall for that (68/55 rev) of thing

You (82dn rev/87dn) me (87dn/88dn/71) a (62 rev/87ac rev) about " (48) of the Common (6dn)s " Well, you are not (63 rev/4ac/76) (79) from me My (31dn rev)s (70) (14/76) it are (44/38ac/36rev/65rev) The (85ac/86) and its (80rev/61/79) authors are too (37/14rev) to be taken (44) (66/44), and the (3) will be a (43/4ac) if it doesn't (38dn/59ac rev) up the entire (87dn rev/13/54rev) anyhow

(75/2rev) and likewise (24ac rev)
(29) (34dn)

*** We invited Mr Quince to contribute a crossword, taking as his theme a recent *Lancet* publication Mr Quince, who as everyone knows is apt to call a spade " a black-suited worker," wrote to refuse in the above harsh terms The solution will appear in a fortnight's time when we will have had an opportunity to find out what he really did say

SELECTION OF ARMY PERSONNEL·
DEVELOPMENT OF THE DSP

CHARLES S MYERS, M D CAMB, F R S

THE Directorate of Selection of Personnel was nstituted in the British Army in the early summer of 941, under the immediate control of the Adjutant-General Its work had been foreshadowed about a year before, when the Army Council decided to introduce election tests into units receiving intakes of recruits This initial phase was entrusted to the director of military raining, who appointed as his adviser a civilian (later aided by 3 assistants) to devise and to arrange for the application of a 20 min test in the various training regiments for artillery, engineers, ASC, armoured corps, nfantry, &c , throughout the country Separate, but imilar, arrangements were also in force for the testing of recruits in training regiments for anti-aircraft duties One great disadvantage of this scheme was the length of time needed to transfer an unsuitably allocated recruit from one arm of the Service to another and to procure the discharge of a recruit found unfit owing to lack of ntelligence or mental instability, for any kind of Army work. In contrast to the practice obtaining in the Navy and in the Royal Air Force, it had been laid down by Parliament that no man could be deemed enlisted until he had been posted by the Ministry of Labour to one arm of the Service (and to its training regiment), after his attendance at one of that Ministry's recruiting centres The DSP was provided with a staff of administrative and technically qualified men and women of military rank to conduct its work

Its institution followed the receipt by the War Office of a memorandum on the selection and allocation of personnel prepared by one of the command psychiatrists of the Army medical services, and of a report from a committee of three psychologists appointed to advise him by the Adjutant-General Both the memo and the report had urged that the new directorate be established, that a non verbal test of intelligence be given to every recruit on his medical examination at the recruiting centres; that mobilisation depots be established throughout the country, to which recruits should first be sent after their attendance at the recruiting centres, and at which a more detailed psychological and psychiatric examination could be carried out *before* their allocation to any arm of the Service, that a permanent staff of non-commissioned officers be provided in the new directorate to carry out the routine application of the necessary tests, and that the directorate should be in the closest possible relation not only with the directorate of the Army medical services (concerned with the problems of Army *health*), but also with the directorates of recruiting and mobilisation and of military training (concerned with the problems of Army *personnel*)

* * *

The first work of the DSP was to select NCOs suitable for the routine work of applying selection tests Most of those chosen had been teachers in civil life and were trained by a staff of commissioned officers who were qualified and experienced in vocational psychology The next step was to introduce a well-tried non-verbal test of intelligence at the recruiting centres By January, 1942, 85% of all intakes were receiving this test in a shortened form, and by March every recruit for the Army (save in Northern Ireland), man or woman, was being thus tested A card was prepared for each recruit on which all information about him that related to personnel problems was entered, and the Hollerith system was adopted for future analysis of the data thus recorded A "job analysis" of the numerous occupations in the Army was also begun, the special mental and physical qualities being systematically ascertained which were required by each

Towards the end of 1941, an experiment was begun of using an extended selection procedure in training regiments Here men underwent tests which assessed mainly clerical, mechanical and signalling aptitudes, and also took a verbal test of intelligence The recruits filled up a form giving their past educational and other histories, interests and hobbies, and they were sympathetically interviewed by commissioned (usually regimental) officers who had been already trained for this important work Recruits of undesirably low intelligence or of doubtfully adequate mental stability were referred by these interviewing officers to the local Army psychiatrist The job analysis of Army occupations made it possible to recommend each recruit, thus tested, interviewed, and considered in the light of his past education and employment and of his present interests and hobbies, for suitable employment in his arm Potential "tradesmen" and men clearly better suited to other arms were able to be transferred early in their Army careers

This small experiment proved so encouraging that the work was gradually expanded It was succeeded in May, 1942, by a small try out of the present general service procedure in 10 units The decision was now made to allocate *all* recruits at the recruiting centres to a General Service corps, and to establish primary training centres throughout the country to which they would be directly sent before allocation to any arm of the Service These important changes came into force in July Many additional officers, commissioned and non-commissioned, were needed by the rapidly expanding DSP. The non-verbal test of intelligence was still given at the recruiting centres, in order that units linked to those arms which required the personnel of highest intelligence should have a selected intake and so reduce troop movements when they were posted Soon after, command personnel selection officers, each provided with NCO and clerical assistance, were appointed for local supervisory duty

* * *

In the selection of officers—another branch of the DSP's work—the psychiatrists have played a more dominant rôle than the psychologists For here there is less need of the discovery of appropriate mental aptitudes Apart from adequate intelligence, the essential desiderata for a good officer are qualities of character and temperament, constituting a suitable personality The vocational psychologist has always regarded tests of personality as far less reliable than those of aptitude He has depended rather on the interview for the assessment of such characteristics as honesty, industry, cooperativeness and sociability Moreover, slight degrees of mental instability or other quasi-psychopathic tendencies are much less important among "other ranks" than among officers In the summer of 1941, a War Office selection board (WOSB) was experimentally set up to improve the methods of assessing officer-candidates and so to reduce the numbers of men rejected from officer cadet training units with consequent waste of time, effort and expense At this unit, during their two or three days' stay, they were confronted by military testing officers with professional and other situations in which they had opportunities of displaying their possession or their lack of initiative, ingenuity, capacity for leadership and courage They were also subjected to psychological tests and to various psychiatric observations, many of them initially of a tentative, experimental character But such success was achieved, particularly by the situation tests and by the interviews with the psychiatrists, that in the following spring WOSBs were established in every command throughout the country Their work is largely clinical, psychiatrists, psychologists, and military testing officers live with the candidates during their stay in the unit, they discuss their independently formed verdicts in the presence of the president of the board who regards them as his technical advisers in determining the acceptability of each officer-candidate and his suitability for some particular arm of the Service

* * *

The director of the DSP, a professional soldier, has to be in intimate touch with those formulating the ever-changing requirements of the Army Though seldom given sufficient notice to allow of really thorough preparation, he has had to produce adequate numbers of the best-suited men and women needed in the various arms of the Service, and to select and train an ever-increasing staff The DSP has received the invariable support and sympathy of the present Adjutant-General It has had to spend much time in devising or adapting tests so that they are better suited to the Army's needs than any hitherto employed in civil life for vocational guidance and selection Some of those suggested have been adopted , others (e g , tests for drivers and gun-layers) have been rejected The value of these tests had to be experimentally determined within the Army before they could be applied on a wide scale Their correlations with other tests already in use has needed calculation , " factor analysis " has also usually been carried out

From the outset the DSP has established close contact with the corresponding but considerably older department in the American Army, which has generously sent to our War Office full information of its experience and methods Similar assistance has been received from those psychologists carrying out corresponding work for the Admiralty and the Royal Air Force The relations of the DSP towards the newly formed directorate of psychiatry within the Army medical services have throughout been cordial The Army psychiatrists have cooperated in all the primary training centres, in the WOSBs, and in field units The consultant psychiatrist or his director, or both, attend the meetings of the advisory committee with the War Office staff of the DSP The psychologist depends on the psychiatrist for the psychopathological examination of men who through deficient intelligence or mental instability need special placing in the Army or discharge In return, the psychologist informs the psychiatrist of the scores obtained from the intelligence test, and possibly will help to detect psychopathic conditions by the responses made to different sections of this test Regular conferences are held at the War Office between the DSP headquarters staff and the advisory committee the members of which have assisted also in several investigations and in reporting on the work at various training centres A conference with civilian psychologists, mostly in charge of university psychological laboratories throughout the country, has also been held, at which various offers of help were received and considered Some offered statistical help, others the free use of their laboratories for research The problem of selecting additional officers for the ATS was effected by liaison with the psychologists at Cambridge engaged upon the selection of specialists for anti aircraft units Contact was also established with the Medical Research Council, one of whose research workers carried out an investigation to devise the shorter form of intelligence test needed at the recruiting centres, another worked on the problem of the avoidance of traffic accidents among Army drivers Technical investigators of the Industrial Health Research Board of the MRC had early been seconded to the staff of the directorate , while the staff of the vocational guidance department of the National Institute of Industrial Psychology was depleted almost to vanishing point, to supply the urgent need for selection work in the Army and Navy Work similar to that of the DSP has been going on both in the Navy and in the RAF Altogether, it will provide sociologists and anthropologists with a valuable survey of the distribution of aptitudes among a vast number of the poulation of this country, and with data which will still be useful after the war, when those now in the fighting Services return to civil life

---

TREATMENT OF BACILLARY DYSENTERY IN THE MIDDLE EAST

J W PAULLEY, M B LOND, M R C P,

FLIGHT-LIEUTENANT, RAFVR

FOR a long time purgation and still further purgation has been widely accepted as the routine treatment for bacillary dysentery There has been variation in the drugs themselves, their length of exhibition and dosage At a recent medical conference in the Middle East the general feeling was that it was better to do nothing at all for cases of bacillary dysentery than to give salines It was agreed that to dehydrate an already dehydrated patient could no longer be considered rational, and the farce of seeing such cases—which require urgent and immediate restoration of fluid intravenously—treated in this way should cease

Results in a large series of cases treated last year on " do nothing, plus fluids " lines were at least as good as those obtained at the same time in a series of saline cases [1] This tendency of most cases to get better anyway is disturbing, because in the mild form of disease (which has predominated this year) it leads to complacency The few cases which do not " do " are lost in a mass of satisfaction and quick discharges

The rationale of treatment with kaolin can be summarised as adsorption of toxins , rest for the gut , and avoidance of dehydration Bacteriophage has apparently been found unsatisfactory by most standards, although it receives recognition on the continent Large quantities of Bayer's polyvalent phage were captured in Libya Pectin and pectinates have been used particularly in the dysentery and acute infectious enteritis of children The mortality of these diseases, below the age of 3 years, remains deplorably high (they are the scourge of children's hospitals) and before the war were one of the big problems confronting municipal authorities

Marshall and his colleagues [2] published results in a series of children treated with sulphaguanidine and reviewed its action , 220 mg is soluble in 100 c cm at body temperature, and this was regarded as the level required in the gut for maximum therapeutic effect , in fact concentrations of 150–200 mg per 100 c cm are achieved by the dosage generally employed On the same dosage the blood values per 100 c cm vary between 3 and 4 mg (compare 9–10 mg sulphapyridine) The guanidine radical makes the drug sufficiently insoluble to remain in the bowel in high concentration In Marshall's 17 children, mainly with Flexner but some Sonne dysentery, 7 who were treated on or before the third day had a rapid and uninterrupted recovery , in the others the reaction was either moderate or there was no demonstrable effect There were no toxic effects, no hæmaturia and no effect on leucocytes The quantity of the drug required for treating each case is considerable, its present cost is high and stocks are limited , so that only cases giving cause for anxiety, or becoming chronic, are at present receiving sulphaguanidine in the Middle East

Reitler and Marberg [3] published results with sulphapyridine in 20 cases, all of which did well Masefield [4] described a series of cases in a Flexner epidemic He gave 1 g 4-hourly of sulphapyridine on the first day, 0 5 g 4-hourly on the second, 0 5 g 6-hourly on the third, 0 5 g three times on the fourth, and 0 5 g twice on the fifth He remarks on the excellent general condition of the patients when they were allowed up, usually about 7 days after the onset

Lieut -Colonel Buttle, who has kindly carried out in vitro experiments, can find no difference between the bacteriostatic effect of sulphaguanidine and sulphapyridine against dysenteric organisms

TREATMENTS COMPARED

The cases compared here were drawn from an area of a few square miles in the Middle East, over the period April-July, 1942 Most cases were mild , a few moderate to severe The cases in this series fall into the following groups (1) Cases on salines (plus sulphaguanidine when considered necessary) at a nearby hospital (2) Cases on sulphaguanidine at this station sick quarters (SSQa) (3) Cases on sulphapyridine at SSQa (4) Cases on sulphapyridine at Flight-Lieutenant Craib's station sick quarters (SSQb) (5) Cases on kaolin at SSQa

These patients all passed blood and mucus, and the laboratory either isolated an organism, or reported indefinite exudate (IE) or bacillary exudate (BE) on the fæces Isolation was low throughout and lower in the SSQ cases than in the hospital series Most of the organisms were Flexner, a few were Shiga, Schmitz and Sonne Personnel were all RAF, RAAF or RCAF There was no selection of cases The hospital series, which actually form the control, were men admitted either before SSQa was rendered fit to accommodate dysentery patients, or were " overflows " when the dysentery wards were full There was no question of admitting severer cases to the hospital , rather were they detained in order that the sulphonamides might be tried further Unlike many of the dysenteries from forward areas all patients in the series were seen and treated within 1 or 2 days It is thought that the groups are strictly comparable The results are summarised in table I

TABLE I—FIRST SERIES FINDINGS IN FIVE COMPARABLE GROUPS

Where treated and treatment	Cases	Av blood days	Av days in bed	Remarks
SSQa Sulphapyridine	43	1 23	4 26	No failures
SSQb Sulphapyridine	30	–	4 96	No failures
SSQa Sulphaguanidine	25	2 16	5 36	2 cases given sulphapyridine, 3 others outstandingly poorer response than in any sulphapyridine case
Hospital Salines *	60		12 6	Shortest case 6 days, longest 65 days 11 cases more than 20 days
SSQa Kaolin	15	2 6	6 1	2 cases given sulphapyridine

* Plus sulphaguanidine in bad or chronic cases

1 *Hospital cases on salines (plus sulphaguanidine when necessary)*—These men were treated with castor oil and salines, the amount of salines varying with the opinion of the medical officer. There were 60 in all, of whom 11 can be regarded as being more severe, or who lapsed into a chronic state These spent more than 20 days in hospital, 1 had a Shiga, 1 a Schmitz, 2 Flexner infections, 2 BE and 5 IE Of those which cleared up without complications, 1 was a Shiga and 13 Flexners, the rest were BEs or IEs All cases of sufficient severity were given sulphaguanidine early, the others received the drug only when they began to show signs of toxicity, dehydration or chronicity (usually 7–9 days after the onset) The shortest period under medical treatment was 6 days, the longest 65 The average period in hospital was 14 6 days Since it takes about 48 hours for the discharge of a patient from hospital to go through, it has been decided to regard this as 12 6 days Further analyses cannot be made on these cases since full details are not available

2 *Cases on sulphaguanidine at SSQa*—A group of 25 patients were treated with this drug, there was no selection of cases Their average stay was 5 36 days The amount of blood they passed was assessed in half days, the total of "blood days" was worked out for each case and averaged 2 16 days per man All cases discharged were put on 2 or 3 days' light or excused duty, while their fæces were observed As the hospital recommendations were the same, this period of non effectiveness has not been taken into account Five of these patients showed an outstandingly poorer response to sulphaguanidine than any did to sulphapyridine, and in 2 of them sulphapyridine was substituted for sulphaguanidine on the fourth and fifth days In one the passage of blood was profuse, and the patient was becoming exhausted, the other was thought to be in danger of becoming chronic The improvement on sulphapyridine was immediate in both cases, and the sulphaguanidine figures benefited by this interference The average total dosage was usually about 80 g per patient, over an average of 3 or 4 days

3 *Cases on sulphapyridine at SSQa*—Treatment from the start with sulphapyridine was given to 43 patients There were no failures. All cases were put on glucose fluids initially, not less than 5 pints daily, and if motions were numerous this was increased to 7 pints a day, plus citrates In a mild case sulphapyridine, 2 g, was given at once, followed by 1 g 4-hourly for 24 hours. At the end of this time decision was made either to continue with 1 g 3 hourly, or to reduce to 1 g 4-hourly The third day was nearly always at the rate of 1 g 4-hourly Only in one or two cases was it necessary to carry on treatment to the fourth day Every effort was made to get the patients on to a light diet, and this was usually achieved by the morning of the third day, if not before, and the patients were allowed up They were well throughout and frequency of motions had nearly always ceased by the second day The total dosage averaged about 20 g per patient over 3–4 days, average stay was 4 26 days per man Average total days of pass [illegible]s 1 23

4 *Cases on sulphapyridine at SSQb*—SSQb was only 600 yards away and the epidemiology corresponded exactly with that in SSQa The dosage was slightly less than that used at SSQa and Flight Lieutenant Craib's criteria for discharge slightly different (negative culture was always awaited) He treated 30 cases The average for these patients' stay in sick quarters was 4 96 days, after which most of them returned to full duty *It is seen that this is better than the sulphaguanidine figures produced in this SSQ* He too had no failures with sulphapyridine

5 *Cases on kaolin at SSQa*—Kaolin powder was given to 15 patients in doses of 2 oz immediately, 1½ oz in 2 hours, 1½ oz after a further 2 hours, then 1 oz three times daily, total dosage varied between 12 and 18 oz In 2 cases it was necessary to interfere by substituting sulphapyridine for kaolin, in one on the seventh day, and in the other on the fifth day Both cases showed signs of drifting to a chronic state Effect of sulphapyridine was almost instantaneous, and the figures for kaolin have benefited thereby Average period in SSQa was 6 1 days Average period of passing blood was 2 6 days

SHIGA OUTBREAK

An isolated Shiga epidemic developed in one camp, during a week in July Though patients were admitted to hospital when SSQa became full, control figures provided by such hospital cases are not yet available The outbreak was vicious and, though both sulphapyridine and sulphaguanidine were found to be efficacious at SSQa the period of treatment required was generally longer than in the five groups compared above Since these Shiga cases had no controls, and were not comparable to the mild or moderate dysenteries of the first series, they could not fairly be discussed with them

The camp had had no dysentery cases for 3 months and the camp adjacent to it was not affected by the outbreak The cause was possibly a carrier in a draft of 70 men who had arrived from India about 7 days before the dysentery began There was altogether a total of 45 cases, 28 of which were treated in SSQa; 17 were sent to hospital In 13 of the cases in SSQa the Shiga bacillus was isolated, and a somewhat higher percentage of isolations of this bacillus was obtained in the hospital cases In view of the completely discrete nature of the epidemic, the number of isolations of the Shiga bacillus, the absence of other organisms, and the severity and similarity of the cases, I think this was a pure Shiga outbreak

Sulphapyridine was given to 15 cases at SSQa Total days of passing blood were assessed as in the previous series; there were 9 Shiga isolations in these cases Sulphaguanidine was given to 13 cases; there were 4 Shiga isolations The days of passing blood and in hospital are shown in table II

Criticism may be levelled at the discharge of patients with this severe infection from the wards in such a short time Under ideal conditions these patients might well have been detained in bed *for a further few days* The dominating factor was, however, accommodation, both here and in the neighbouring hospitals The procedure adopted was similar to that in the first series · cases as soon as they had been free from blood and mucus for 2–3 days were discharged to 3–4 days excused duty, complete rest, and kept under the observation of the nursing staff All their motions were observed, and for 2 days after

TABLE II—FINDINGS IN A SHIGA EPIDEMIC TREATED AT SSQa, AND IN ALL CASES TREATED PERSONALLY

Series	Treatment	Cases	Av blood days	Av days in bed	Av total dosage	Remarks
Shiga	Sulphapyridine	15	2 66	5 7	34 g	1 drug rash 1 relapse
Shiga	Sulphaguanidine	13	4 73	8 01	142 g	1 drug rash
All cases*	Sulphapyridine	63	1 74	4 8		
	Sulphaguanidine	83	2 55	5 59		

* These final figures for all cases treated by Flight Lieutenant Paulley, including the Shiga outbreak and some recent cases bring his experience up to date —Ed L

discharge a light diet was provided by the sick quarters' kitchen They were made unfit for posting to other units for a week

Sigmoidoscopy was carried out in all but 4 cases There was one relapse in the sulphapyridine series while under outpatient observation. He was readmitted and rapidly cleared up in 2 days without further treatment Average total dosage of sulphapyridine was 34 g , the highest total amount to one patient was 43 g Average total of sulphaguanidine was 142 g , Nausea and vomiting were not serious, and affected patients on both drugs Two drug rashes were encountered, one a sulphaguanidine case, and the other a sulphapyridine They were morbilliform , one became confluent, but both cleared in 4 days

The main observations were , The more rapid reduction of stools, and disappearance of blood and mucus in the sulphapyridine cases than in those on sulphaguanidine , and the fact that cases on sulphapyridine became apyrexial within 24 hours, whereas cases on sulphaguanidine were often pyrexial for 4–5 days

DISCUSSION

In the first series of 73 mild and moderate cases, sulphapyridine used from the onset was not followed by a single failure, or by any case in which the clinical response was not immediate (i e , within 1–2 days) In no case on sulphapyridine in the first series was blood passed for more than 3 days On the other hand, of 52 cases receiving the present recognised dosage of sulphaguanidine, 5 cases failed to show satisfactory response

In the Shiga epidemic, the figures were even more conclusive , 5 out of 13 sulphaguanidine cases fared worse than any sulphapyridine case From published work and from observation of other cases treated in hospitals in the Middle East, it seems that though sulphaguanidine is often as effective as sulphapyridine, cases commonly occur in which it appears to be inferior This may be due to one or more of the following causes (1) Dosage of the drug may not be high enough (though the dosage commonly recommended has been shown to provide a bowel concentration of 150–200 mg %—the level advocated for this drug) (2) Sulphapyridine has a greater bacteriostatic action than sulphaguanidine in vivo (3) The attainment of a high bowel lumen concentration may, after all, not be as essential as the attainment of a high blood concentration in dysentery

Superficially, it looks as though there may be some truth in the last hypothesis For years the intestinal diseases have been attacked from the viewpoint of local action Intestinal disinfectants have been used and vaunted, but have failed to stand the test of time May it not be a preconceived and mistaken idea to aim at a high bowel concentration of sulphonamide ? True the sulphonamide compounds are effective as local agents, but though bacillary dysentery is pathologically a disease of the colonic mucous membrane, it is worth remembering that a tonsillitis or a pharyngitis is more effectually treated by a high blood concentration of sulphonamide than by painting the drug on those areas A severely infected wound would not be treated by local sulphonamide alone

In other conditions susceptible to sulphonamides the importance of catching the disease early in the acute stage has been emphasised, and presumably this is equally necessary in dysentery Where sulphaguanidine is scarce there seems to be a good case for using sulphapyridine, not only because the results in these two small series have been encouraging but because the drug is more plentiful, less is needed for each case, and it is cheaper On the other hand, there is more danger of agranulocytosis with sulphapyridine, which necessitates white counts if the drug is given for longer than 4–5 days, and it gives rise to more minor toxic phenomena In the first series reported here no patient required sulphapyridine for more than 4 days In the Shiga epidemic white counts were done in 11 cases, and there were a few examples of minor toxic phenomena among these cases, some patients vomiting on sulphaguanidine as well as some on sulphapyridine

Advantages of sulphonamides over other forms of treatment are the speed of recovery, and the facts that solid food can be taken early, that the patient does not need a long convalescence, and that discomfort is cut short If sulphonamides are used as a routine, however, there is always a danger that a dehydrated patient may get crystallisation in the renal tubules, with anuria In the Middle East, of course, supply and cost must also be considered

One severe case developed hæmaturia after 2½ days of sulphapyridine It was immediately discontinued, but his dysentery was cured Hæmaturia cleared in three days on fluids (forced) and massive alkali treatment by mouth He was a bad patient and would not take his fluids well in the first place It has been routine since this case to prescribe alkali—pot cit , gr 40 2-hourly—in the initial stages in all cases passing a large number of stools on admission It is understood from the Egyptian Faculty of Medicine that a urine pH of 11 is necessary before crystallisation can certainly be averted The importance of a daily urinary output of at least 1500 c cm has been stressed by Thompson, Herrell and Brown [5] of the Mayo Clinic as the surest means of preventing this complication

The disadvantages of supply and cost are outweighed, from the military as well as the civil aspect, by the remarkable saving on the period of non-effectiveness In this paper it is shown as 8 clear days per individual over the time with saline treatment

SUMMARY

Results in five comparable groups of cases of mild and moderate dysentery among Air Force personnel in the Middle East were compared Most were of the Flexner type

In 60 cases treated with salines, supplemented with sulphaguanidine later if necessary, the stay in hospital averaged 14 6 days (equivalent to 12 6 days in bed)

In 25 cases treated with sulphaguanidine the average period in bed was 5 36 days

In two groups of 43 and 30 cases treated with sulphapyridine the average periods in bed were 4 26 and 4 96 days

In 15 cases treated with kaolin (2 supplemented with sulphapyridine later) the average period in bed was 6 1 days

In an outbreak of severe Shiga dysentery the average periods in bed were 5 7 days in 15 cases treated with sulphapyridine and 8 01 days in 13 cases treated with sulphaguanidine

It is concluded that treatment with sulphonamides is superior to other methods tried, and that sulphapyridine has advantages over sulphaguanidine

Sulphonamide treatment should be begun early in the acute phase before the disease has spread or become chronic

Wing Commander J H L Newnham first suggested that strictly comparable series of dysentery cases should be treated by the various methods available I wish to thank Flight Lieutenant Craib for permission to record the results of his cases treated with sulphapyridine, and also Group Captain O'Malley, Wing Commander Lee Potter, and Major Dick for their help and criticism

Status of the General Surgeon —The general surgeons on the staff of the Johannesburg General Hospital have issued a manifesto in which they deplore the prevalent impression that general surgery as a specialty is rapidly becoming defunct They argue that there is apt to be a confined outlook and lack of broad perspective in small specialties The one system concerned in any particular specialty is but a small part of the body, and its diseases are often considered without due regard to the whole organism The present-day tendency to embark on specialism soon after qualifying never permits such specialists to appreciate the immense importance of the condition of the rest of the body in relation to their own small sections of it In the teaching of students particularly, says the manifesto, the teacher must be able to consider the whole body in relation to disease and injury

ANTERIOR AND POSTERIOR FOSSA CEREBRAL TUMOURS

CLINICAL STUDY OF 122 CASES

G JOHN DIXON
M D DUBL, M R C P
LATE REGISTRAR

GERALD FITZGERALD
M B N U I, M R C P
LATE RESIDENT MEDICAL OFFICER

NATIONAL HOSPITAL, QUEEN SQUARE

SINCE Hitzig and Fritsch discovered the motor area in 1870, certain physical signs and symptoms have come to be regarded as indicating lesions in various parts of the brain Clinicians, however, led by Hughlings Jackson (1871) have increasingly appreciated that the brain works as a whole, thus extensive lesions in one area may cause effects usually associated with lesions remote from it (Collier 1930) Hare (1931), Gordon (1934) and Jefferson (1939) have noted that anterior fossa tumours may mimic the symptomatology of tumours in the posterior fossa, and stressed the difficulty of deciding in which of these regions a cerebral tumour may lie Some tumours in the posterior fossa may also produce symptoms suggesting a lesion in the anterior fossa, though little attention has hitherto been paid to them in published work

Recently we have observed several cases which illustrated these two points, and led us to analyse the clinical symptoms of all cases of proven anterior and posterior fossa tumours in the National Hospital between January, 1938, and October, 1940 Only cases where the diagnosis was verified either at operation or autopsy were considered The 122 cases included 56 tumours of the anterior fossa and 66 of the posterior fossa The anterior fossa tumours were 40 frontal gliomata, 2 frontal cysts of undetermined nature, 11 meningiomata of the sphenoidal ridge, 2 meningiomata of the falx, 1 sarcoma arising from the falx The posterior fossa tumours were 12 cerebellar gliomata, 9 cerebellar cysts of undetermined nature, 7 medulloblastomata, 4 gliomata of the floor of the fourth ventricle, 2 ependymomata, 10 hæmangiomata, 17 neurofibromata, 3 meningiomata of the posterior fossa, 1 cholesteatoma, 1 vascular tumour of the lateral recess

The examination was confined to those signs and symptoms which, while generally useful in differentiating between tumours in these two situations, may cause confusion when they happen to be anomalous An analysis of such signs and symptoms is given in the table, they were mental changes, epileptiform convulsions, nystagmus, ataxia, the grasp reflex and an absence of all localising signs

INCIDENCE OF SIGNS AND SYMPTOMS IN 122 CONSECUTIVE TUMOURS IN THE ANTERIOR (56 CASES) AND POSTERIOR (66 CASES) CEREBRAL FOSSA

Symptom or sign	Total cases	In anterior cerebral fossa	In posterior cerebral fossa
Major fits	28	23	5
Loss of consciousness with—			
Minor motor disturbances	8	5	3
Fits and/or minor fits	36	28	8
Mental disturbance	58	42	16
Drowsiness	21	14	7
Nystagmus	49	7	42
Static tremor	9	8	1
Cerebellar ataxy	29	0	29
Slight irregularity of movement—			
Ataxy or tremor	15	2	13
Unsteadiness	55	13	42
Absence of all localising signs	20	13	7
Grasp reflex	5	5	

DISTRIBUTION OF SYMPTOMS

Mental changes were common in both types The most characteristic change was drowsiness and lethargy In 21 (16% of the whole series) this was so severe that the patient spent the greater part of his time asleep with occasional periods of misdirected voluntary motor activity, when roused however he would appear rational and cooperative Of these, 14 had anterior fossa and 7 had posterior fossa tumours Mental abnormality other than drowsiness was found in 58 cases (48%), these included affective disturbances, disorders of judgment and will, fixation of attention, alteration in basic mood, loss of inhibition and lack of spontaneity 16 (25%) patients exhibiting one or more of these changes had tumours in the posterior fossa and 42 (75%) in the anterior fossa Among the latter were the 12 cases showing the greatest degree of psychological abnormality in the series As a rule the mental changes were of recent origin in the posterior fossa group and may well have been due, as Stewart and Holmes (1904) suggest, to increased intracranial pressure There were 2 noticeable exceptions to this rule in one the mental change had been present for 25 years, and in the other for 15 years In these 2 cases the mental disorders may have been a coincidence Schuster (1902) found mental changes in 55% of 588 verified cerebral tumours, and in a discussion at the Royal Society of Medicine in 1931 Kinnier Wilson stated that the localising value of mental symptoms in cases of cerebral tumour was slight Most of those who took part in the discussion agreed

Epileptiform convulsions have long been known as a common feature of cases of cerebral tumour, but the work of Lennox and Cobb (1928)—who noted that cerebral tumours were found in only 3 5% of epileptics at autopsy—established that fits alone, in the absence of other symptoms and signs, are of little significance in the diagnosis of a cerebral tumour In our series, fits occurred in 28 cases, and a history of "fainting attacks" in a further 8 On careful investigation of the history it seemed that most of these fainting attacks were epileptiform in nature Fits occurred in 5 cases of posterior fossa tumours and loss of consciousness with minor motor disturbances in 3, giving an incidence of convulsive states in 12% of cases This is significantly greater than the figure of 0 6% for epilepsy in the adult male population of London (Galloway et al 1920), and must be due to an association between posterior fossa tumour and epilepsy Fits have been noted in cases of posterior fossa tumour by Collier (1904), 3 cases out of 26, MacRobert and Feinier (1931), 5 out of 45 cases, and Webster and Weinberger (1940), 34 out of 158 cases The association was denied by Parker (1930), who failed to find a single instance in 91 cases of posterior fossa tumour In the 1931 and the 1940 series, major epilepsy was relatively rare, while tonic and localised clonic attacks and syncope accounted for most of the cases.

In our series, 4 patients with posterior fossa growths (multiple neurofibromata, a cyst and a glioma of one lobe of the cerebellum, and a glioma of the floor of the fourth ventricle) all suffered from epileptiform fits One of these had, in addition, local clonic attacks which did not proceed to unconsciousness Another boy of 17 with a medulloblastoma had attacks of tonic bilateral adduction of the arms, followed by unconsciousness without any clonic movements Such further details as were available indicated that these attacks were similar to the classical cerebellar fits described by Hughlings Jackson in 1871 Of the 3 additional cases with loss of consciousness, one, a boy aged three years with a left cerebellar cyst, was reported to be stiff and unconscious with his legs extended during two at least of three so-called fainting attacks Thus it seems that a posterior fossa tumour predisposes to convulsions, occasionally these may be cerebellar fits, but more usually they are epileptiform in character

Epileptiform fits occurred in 23 cases of anterior fossa tumours 17 gliomata, 5 meningiomata and 1 sarcoma This gives an incidence of 41% in anterior fossa tumours Jefferson (1939) found convulsive attacks in 20% of 20 cases of frontal meningiomata and in 50% of 30 cases of gliomata of the same region Hyland and Botterell (1937) found it in 46% of 30 frontal gliomata An additional 5 cases in our series of anterior fossa tumour suffered from recurrent syncope

Nystagmus was regarded by Stewart and Holmes (1904) as one of the most valuable localising signs of cerebellar tumour They found it at one time or another in almost all their cases In our series, persistent nystagmus on lateral deviation was observed in 42 (64%) cases of posterior fossa tumour This does not include nystagmoid jerks observed at irregular intervals In addition, 7 (10%) cases of anterior fossa tumour also showed this sign Hare (1931) found that 19 of 50 unselected frontal tumours showed no evidence of incoordination or nystagmus, while another 5 of the same series simulated closely a lesion in the posterior fossa Comparable findings are recorded by Gordon (1934) and Jefferson (1939) In our series, nystagmus usually did not cause any great difficulty in diagnosis when present in anterior fossa cases, since most of these had other gross signs referable to a lesion in this region In 19 of our cases, nystagmus was an isolated localising sign, in 18 of these the tumour lay in the posterior fossa Stewart and Holmes (1904) described the typical nystagmus of cerebellar disease as " a deliberate jerking movement to the side of the lesion, when the eyes are deviated in that direction, with gradual recession to the middle plane, in conjugate deviation of the eyes to the opposite side the movements are of smaller range, but occur in more rapid succession " In our series nystagmus of this type occurred in 28 cases, 18 of which exactly corresponded with that description In 6, however, deviation of the eyes to the side of the lesion produced the finer and more rapid movements, and in 4 the tumour lay in the midline. Of the 28, 8 had unilateral intracerebellar lesions, in 7 of which the nystagmus conformed to the classical description

Ataxia —Irregularity of movement may be due to cerebellar ataxia or tremors In cases where the irregularity of movement is slight it may be difficult to differentiate between the two on this sign alone Such slight irregularities were found in 2 cases of tumour in the anterior and in 13 cases of tumour in the posterior fossa In most of these, however, other signs were present which pointed to the correct diagnosis Cerebellar ataxia was present in 29 cases, and all had posterior fossa tumours In addition, 3 anterior fossa tumours with hemiparesis had incoordination of movement in some respects resembling cerebellar ataxia on the hemiparetic side Static tremors similar to those described by Stewart (1906) were found in 10 cases, 9 of these had tumours in the anterior cranial fossa, and the 10th patient was found to have a cyst in the right lobe of the cerebellum This was an unusual case, since epilepsy had been present for twenty years In most of the 9 cases of frontal tumour with tremor this was greater on the side opposite to the lesion Another type of tremor, probably due to hypotonia (Holmes 1922), develops in many cases of cerebellar lesions on fatigue We have not found that this type of tremor causes much confusion, and since it is almost always associated with ataxia no special records were made

The *grasping, groping reflex* (Wilson and Walshe 1914) was observed in 5 cases of anterior fossa tumour Hyland and Botterell (1937) found this phenomenon in 1 out of 30 frontal gliomata, and Jefferson (1939) in 2 out of 50 frontal meningiomata and gliomata No such reflex was found in any case of posterior fossa tumour

Absence of localising signs —The absence of all localising signs in a patient otherwise known to have a cerebral tumour is regarded by many (Collier 1904, 1929) to be good evidence of a frontal or a right temporal location Such was found to be the case in 13 (23%) examples of anterior fossa tumour in our series We were impressed by the frequency with which drowsiness overshadowed the picture in posterior fossa tumours, so that either no signs relating to this region were obtained, or the signs consisted of one minor abnormality not constantly present In 3 cases at least, a left cerebellar hæmangioblastoma, neurofibromata of the 9th and 10th cranial nerves and a medulloblastoma of the roof of the fourth ventricle, diagnosis was only made after ventriculography In a further 4 cases, the physical signs on which the diagnosis was established were either likely to be missed by most observers or insufficient to warrant their being used as localising (10%) therefore of the posterior fossa gr ed by localising physical signs

SU

There seem to be inher
tion of growths in the an
fossa if too great

attacks, irregularity of movement, mental changes, nystagmus, or the absence of localising physical signs

In a consecutive series of 122 cases from the wards of the National Hospital, proven by autopsy or operation, 56 cerebral tumours were localised in the anterior and 66 in the posterior fossa

The grasp reflex in 9% of the anterior group, and cerebellar ataxia in 44% of the posterior group, were the only unequivocal signs

Nystagmus was seen in 10% and epileptiform fits in 41% of the anterior group, the incidence of similar findings in the posterior group was 64% and 8% Mental change was so common in both the anterior (75%) and the posterior groups (25%) that it should not be considered of value in localisation

All localising physical findings were absent in 23% of the anterior fossa group and in 10% of the posterior fossa group, this finding is unusual

We wish to thank the honorary staff of the National Hospital for permission to examine these cases, particularly Dr Gordon Holmes for his help and advice

SCABIES AND INTELLIGENCE

KENNETH MELLANBY, B A CAMB, PH D LOND
SORBY RESEARCH FELLOW OF THE ROYAL SOCIETY

A L NORTHEDGE
B SC LOND

C G JOHNSON
PH D LOND, MAJOR, RAMC

Hodgson (1941a and b) has shown that groups of patients suffering from different skin diseases may differ in their average intelligence In particular he found from a series of patients with skin diseases that those with parasitic infections, including scabies, contained the highest proportion of men of inferior intelligence In order to corroborate Hodgson's findings, and to see whether certain types of scabietic infection (for instance, with or without secondary infection) were correlated with different types of intelligence, several hundred patients were examined to assess their intelligence

The test used was the RECI Progressive Matrices (Penrose and Raven 1936, Raven 1939, 1942) Hodgson used sets A, B and C only, we used the whole five sets, A, B, C, D and E, in order that our figures could be compared with the " norms " which have been obtained by examining very large numbers of men on their entry into the Forces The men were allowed 20 minutes in which to attempt the test The highest mark obtainable is 60, and with this limited time test several hundred thousand army recruits gave scores which may be divided into grades as shown in the table, these results may be considered as norms

In every group of men examined some give scores which should be placed in another grade as " unreliable " These unreliable scores are distinguished by being significantly different from the average results in their " break up " of the answers for the different sets of questions The exact nature of a so-called unreliable score is best explained by means of an example The five sets, each of twelve questions, are of increasing difficulty and the average marks (for correctly answered questions) for men whose total was 22 were 10, 7, 3, 2, and 0 for sets A, B, C, D and E respectively If a total of 22 is scored, and if for any two sets the result is more than 2 marks different from the average, the result is u

Thus, a score of 22 made up as 7, 10, 3, 2 and 0 would be considered unreliable In analysing our figures we have treated separately 38 results which appear to be unreliable. Incidentally, whether or not the unreliable scores are included in the calculations given below, little difference is made to the final results

RESULTS

A series of 316 men were subjected to the test , 25 of these who were tested before their skins had been examined, were found not to be suffering from scabies and their results have been ignored , causes outside our control interrupted 3 of the tests and these too have been neglected , the 38 unreliable scores were treated separately In the table the results in the remaining 250 reliable scores are compared with the normal distribution and it will be seen that there is no significant difference at the lower end of the table, although our patients appear to include a rather low proportion of men of superior intelligence This result is not in agreement with Hodgson's conclusion that a high proportion of scabies patients are of lower than normal intelligence

TEST SCORES IN NORMAL RECRUITS AND IN PATIENTS WITH SCABIES

Intelligence grade	Marks	Per cent of	
		Norms	Scabies
1	45 or over	15 8	10 5
2	39–44	25 7	22 5
3	33–38	23 9	26 5
3	27–32	16 1	21 0
4	18–26	13 5	13 5
5	17 or less	5 0	5 5
Unreliable		5 0	13 2

The main criticism of Hodgson's results is that his norms are too high With a total possible score of 36 only 5% of his control group scored 19 marks or under In the norms used here—obtained from much larger numbers of subjects—out of a possible total of 60 marks 5% of the men scored less than 17 We believe that if Hodgson had used norms obtained from a larger group of subjects and not from a selected population like an RAMC intake his results obtained from scabies patients would not have been very different from ours

In the Army at present there is a good deal of propaganda about conditions such as scabies, and the men are urged to report sick as early as possible if they detect any such complaint One might expect therefore that the more intelligent man would report himself sick and the dullard would find little cause for complaint and only be detected at a routine inspection In all, 176 men reported themselves sick and 72 were detected at routine inspections (no data were kept in the other 2 cases) There appears to be no difference in the average intelligence of these two groups, the average score for the self-reporting cases being 33 9 marks whereas that for the men detected at routine inspections was 34 2

Scabies is usually detected because a patient itches and complains of this symptom or because he relieves his itching by scratching, and the scratch marks are themselves observed It was thought possible that less intelligent individuals might support larger parasite populations before sufficient itching was noticed and scratching provoked to lead to the detection of the complaint Actually this does not appear to be the case We have developed a technique for estimating the intensity of the parasitic infection accurately, and, when we divided the men into two approximately equal groups, those with a lower number of parasites (126 men) obtained on the average 33 0 marks and those (124 men) with a higher number scored 34 9 The phenomenon of itching is a complex one and it is perhaps not surprising to find it bearing no direct relation either to intelligence or parasite population

In most *cases neglected* scabies is complicated by secondary infection which is as a rule more serious in its consequences than the primary sarcoptic attack One might expect the intelligent man to be concerned about the onset of secondary infection, whereas the dullard would have nothing done about it In this investigation 168 cases showed no secondary infection and 82 some degree of it The average score for two groups was 33 5 and 34 9 respectively

Among the 13% (38 cases) of scabietic individuals who gave scores which had to be considered unreliable our figures were 5% higher than the norms ; this may be because many patients with scabies are suffering from anxiety, perhaps because many of them believe they have contracted a venereal disease

SUMMARY

Men suffering from scabies had their intelligence tested by the RECI progressive matrices test The results indicated that they were mentally an approximately normal sample from the Army There was nothing to suggest that this group contained an abnormally high proportion of men of low-grade intelligence

No significant difference in intelligence was discovered between men who reported themselves sick and those who were detected at routine inspections , those with few and those with many parasites , or those with or without secondary infection

We wish to thank Dr. F J Esher for his advice and Major J D W Pearce and Major G A Hodgson for reading and commenting on the manuscript

DIAGNOSIS AND TREATMENT OF SCIATIC PAIN

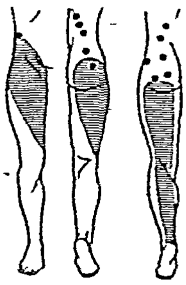
MICHAEL G GOOD, M D BERLIN, L R C P E
CAPTAIN, RAMC

(From a military hospital)

IN the Army I have met with a large number of men complaining of a dull ache sometimes extremely severe, down the back of the thigh, sometimes extending as far as the heel and sometimes stopping at the popliteal space The pain may be referred to the outer aspect or front of the leg ; it is increased on standing and often worse at night In my view the origin of this pain is almost always muscular Well-defined myalgic spots harder than the surrounding muscle, can be found in the quadratus lumborum, glutei or tensor fasciæ latæ muscles Pressure on these produces agonising pain, sometimes similar in character and distribution to that complained of, and persisting for some minutes The distribution of the spots does not correspond with that of the pain complained of, which is a referred one Injection of procaine into these spots removes both the local tenderness and the referred pain

EXAMINATION AND TREATMENT

Hard pressure is made with the right thumb, or with the index or third finger on the origin, *insertion* and along the border and course of the muscles to be examined Wherever possible the muscle or tendon should be pressed against a bone The pressure has to be made so as to cause only moderate discomfort or slight pain when applied to a normal muscle, and patients easily distinguish the difference between such a pressure on a normal muscle and on a myalgic spot Pressure on a myalgic area elicits so agonising a pain that the patient winces and sometimes says spontaneously "You have got it sir" In muscular sciatica the myalgic areas are, as a rule, to be found in the edge of quadratus lumborum, the origin and border of upper (muscular) part of tensor fasciæ latæ, in the gluteus medius about ¾ in. below the iliac crest and in the course or rarely the origin of gluteus maximus The figure shows characteristic examples of pain distribution and myalgic spots



Areas of pain (shaded) and myalgic spots in two cases.

Rapid, effective and permanent relief can be obtained by injection of procaine into each myalgic spot, care being taken to infiltrate the whole muscular area I use procaine hydrochloride, 1 g, with phenol, 0 5 g, made up with saline to 100 c cm in sterile rubber capped bottles The myalgic spots are mapped out very carefully on the skin with a blue dermatograph, the pencil marks are painted over with iodine and 1–2 c cm of the procaine solution is injected intramuscularly into each myalgic spot The results of a thorough and accurate injection are almost instantaneous relief of pain, relaxation of the contracted muscle as evidenced by palpation, and disappearance of local and referred pain and the wincing when the myalgic spot is pressed

RESULTS

In the Army I have seen, among 700 cases of myalgia, 65 officers and other ranks who suffered from the syndrome of "sciatica" In all the cases the myalgic spots described could be located in the hip muscles by objective criteria All but one case were fully relieved and returned to duty in a relatively short time The one case not cured turned out on psychiatric investigation to be due to simulated pain I am confident that these favourable results can be obtained by every physician who takes the trouble to locate myalgic spots and apply the appropriate treatment I treated the 65 cases in medical inspection rooms and at two military hospitals, and was therefore not able to follow them all up, in several patients seen up to 10 months after the last treatment the permanent results were good

---

Reviews of Books

Disorders of the Blood

(4th ed) L E H Whitby, MD Camb, FRCP, C J C Britton, MD NZ, DPH London J and A Churchill Pp 595 28s

In producing a new edition of this well-established book the authors, by including a good deal of new material, have sought to bring it properly up to date Unfortunately the additions have not always been wholly assimilated, nor the contradictory older sections thoroughly pruned, this is especially true of the first two chapters A new plate (plate III) sets out very well the classification and development of the erythroblasts according to present-day ideas, the scheme of Israels having been selected as representative, and plate IV also shows good reproductions of hæmoglobinated megaloblasts, and normoblasts, using these names in the same way, but plate II and tables II and IX are still retained, and these show a quite different kind of megaloblast—that of the schemes popularised by Doan and his followers some years ago This confusion is found throughout the text wherever erythropoiesis is mentioned, either normal or pathological, so far as we can see "megaloblast" between inverted commas indicates the cells illustrated in plates III and IV, megaloblast without inverted commas indicates the plate II cell There must be few hæmatologists nowadays who do not agree that megaloblastic changes in the marrow are limited to pernicious anæmia and allied conditions, and this is properly illustrated in plate III, but in the text megaloblasts are described as being present in the marrow of "simple anæmia," and the table of normal marrow cells (p 561) shows megaloblasts present up to 4% The scheme used in plates III and IV is now sufficiently accepted to allow the presentation of a much more uniform account of erythropoiesis than the authors give here The rest of the book maintains previous high standards It is interesting to see that Wintrobe's "morphological" classification of anæmias is used and is fully set out in table VII, this table will be puzzling to those brought up on "colour index" classifications, since the term "hyperchromic" doesn't appear at all, but it is a step in the right direction Full descriptions are given of recent work on methæmalbumin, the rôle of the porphyrins, the importance of vitamin K and glandular fever The section on blood groups is unusually complete and tackles the subdivisions of group A and the recently described "Rhesus factor" As might be expected, the section on blood transfusion and blood substitutes is thoroughly practical The discussion of the differential diagnosis of pernicious anæmia is very complete, and a useful table is given on p 200 of the various liver and stomach preparations available in this country for its treatment The increased iron requirements in adolescence are emphasised, and the theory that copper is necessary for erythropoiesis is supported The section on technique is practical, but to give 7½ pages to descriptions of how to determine red blood-cell diameters and only 2 pages to bone-marrow biopsy seems to be the wrong way round in view of the relative importance of these two investigations in differential diagnosis, the work of Jeanneret on the difficulties of obtaining reliable post-mortem marrow specimens is fully noticed The make-up of this book is familiar, and the publishers have again shown that it is possible to produce a book of nearly 600 pages with 8 excellent colour plates at a reasonable price

Society and Medical Progress

Bernhard J Stern, PhD, lecturer in sociology, Columbia University Princeton University Press, London Humphrey Milford, Oxford University Press Pp 264 18s 6d

Dr Stern cuts across the arbitrary barriers that have taken medicine out of the context of other sciences and social institutions, and shows that it cannot develop and never has developed in isolation—that its rôle and achievements are conditioned by the soil in which it is rooted His dynamic interpretation of medical history is at once stimulating and revealing The impact of social needs on medicine has been brought into relief, in England and America, by the problem of providing adequate medical care for those with low incomes Medicine, by reducing mortality and lengthening the life span has had repercussions on social life, chronic and degenerative diseases have become prominent, and this has affected public policy in the care of the aged Medicine has encountered opposition in its progress—from within the profession, from workers in other branches of science, and from non-scientific circles In each case, as Dr Stern shows, resistance to change has depended on social and economic factors

A Pocket Medicine

G E Beaumont, DM Oxfd, FRCP, physician to the Middlesex Hospital London J and A Churchill. Pp 202 10s 6d

The essentials of a bigger text-book are here condensed into 200 pages, and perhaps in war-time a reliable pocket medicine has its special place (besides the pocket) It is one of the minor horrors of war that it also has its special price Those who know Beaumont's fuller text-book will recognise this volume as an expertly abbreviated edition, it contains an astonishing amount of information and surprisingly few omissions The paper and printing are first-rate, a noteworthy advantage if it is to be read in war-time trains with war-time crowding and lighting The 15 chapters are arranged mainly according to bodily systems, but with special sections on tropical diseases, infectious diseases, parasitic worms, poisons, the ductless glands and metabolic diseases Some lack of balance is inevitable thus peripheral neuritis receives as many lines as ochronosis But for revision, provided he has founded his clinical learning on a rock, many a student will be glad to slip this book into his pocket

Illustrations of Regional Anatomy

4th ed, sections I–V, 3rd ed, sections VI and VII E B Jamieson, MD Edinburgh E and S Livingstone Plates 318 60s

The third edition of sections I–V of these well-known books was unfortunately lost by fire, so Dr Jamieson has quickly produced the fourth edition of these sections together with the third edition of sections VI and VII The coloured plates represent dissections of the regions concerned The fourth edition of sections I to V show, in general, that accuracy to be expected from the author In the interests of the learner, it is perhaps worth noting that the relation between the radial artery and the muscular part of the long flexor of the thumb might be misunderstood from plates 27 and 28 of section VI, showing the deep front of the forearm, this is only a detail, but regional anatomy is composed of such details, and if one of them is wrongly conceived, the whole picture must suffer Section VII deals with the lower limb fully and successfully The whole production reflects credit on the author, publishers and printers who faced and made good the damage

Supplement to THE LANCET, Nov 21, 1942

MEDICAL PLANNING RESEARCH

INTERIM GENERAL REPORT

I Introduction

1 MEDICAL PLANNING RESEARCH has set out to present a plan for the future of medicine in Britain. Through the medical press, it has invited membership from those who are prepared to play an active part in its work. Members who have prepared drafts for this interim report have been, for the most part, doctors qualified less than 21 years, or others connected with the health services who are not over 45. Members who wish to act as critics of the report are of all ages. Drafts have been received from over 200 members, and have been edited by a small editorial group. Since the report is intended as a basis for discussion, there has been no attempt at making the editorial group representative. The report is now presented for examination and detailed criticism by the members of MEDICAL PLANNING RESEARCH, and anyone else who may wish to do so. For their convenience, paragraphs are numbered consecutively throughout. Criticisms should be sent to MEDICAL PLANNING RESEARCH, c/o The Connaught Hospital Walthamstow, London, E 17. So as to give members serving in Middle East and other distant parts full opportunities for criticism, it is not proposed to prepare the final report until at least 6 months after this interim report has been circulated.

2 Members of MEDICAL PLANNING RESEARCH are pledged to two guiding principles. First, they agree to proceed by scientific methods. This involves the collection of all available evidence, belief according to the evidence, and readiness to admit error whenever shown by the evidence. It involves also an attitude of impartiality in dealing with matters whether of unusual novelty or sanctioned by time-honoured tradition. Secondly members agree to place first in their planning proposals the maximum benefit of the maximum number of patients. If this aim is to be achieved, it is only one degree less important to have optimum conditions for those who serve the patients. But if these two conflict, the patients must always have precedence. The word "patient" is defined as any person receiving, or needing to receive, the help of medicine in its broadest sense—that is, the prevention and treatment of physical and mental illness, and the production of positive health, physical and mental. In computing the maximum number of patients, the only practical method is to count each individual as one. Attempts to place different social values for health purposes on the labourer and the lawyer, the director and the dustman are not only impossible, they are foreign to the whole spirit of medicine.

3 This interim report has two parts. The first is a broad general outline of our proposals for the future of medicine. The second will deal with the numerous detailed problems which must be fitted into the broad picture. Ultimately it is intended to publish the final revised versions of both parts as a book.

4 At the start of our task, we have to recognise two groups of problems connected with, but not strictly a part of, medical planning. First, medical organisation is very largely determined by the social pattern of the society in which it exists. The nature of this pattern imposes certain limits on our efforts. Thus, for example, a small island community of a few thousand people could not maintain a teaching hospital. If it had to train its own doctors, it would have to revive the apprenticeship system. Our present medical system has grown up in a strongly individualistic society, with many special virtues and special faults, in consequence. We shall examine the probable social pattern of postwar society, so as to see the framework inside which the new medical services will have to be built. We shall have comments to make on this framework from our special medical point of view.

5 The second group of problems connected with, but not strictly a part of, medical planning are those of environmental planning for health and happiness. Whereas in the first group, we are concerned with the changes that are likely to occur, and their effect on medicine, in the second we are concerned with those which ought to occur if maximum health of mind and body is to be obtained. The first is, as it were, our minimum, the second is our optimum. We shall have, then, to add to our study of the pattern of postwar society, a study of the special measures which should be taken, inside these limits, to achieve the highest measure of positive mental and physical health. We shall study these two sets of problems concurrently from five different aspects: population, productive capacity, poverty, purchasing power, physical planning of town and country.

PART I

Minimum and Optimum

II Population

6 Among demographers (scientific students of population) there is substantial agreement on the following points:—

(i) If the population trends which existed in Britain before the war continue indefinitely, the rate of increase will get steadily less. In due course the population will become stationary at a maximum about 2 million more than the present figure of 46 million. This will be between 1951 and 1961. Thereafter it will steadily decline. Estimates for the population of England and Wales (now about 40 million) in 100 years' time range from 20 million to 4 million. These estimates depend on one assumption—that the prewar trends continue unaltered. But the upper limit of the birth-rate for the next 20 years is already determined by the number of girl children born in the past 25 years. In demography one has to look ahead a long way if one is to take check of a declining population.[1]

(ii) Concurrently with the slowing of the growth of the population, there will be a shifting of the age-grouping, from the younger to the older. The Registrar-General has forecast that in 1971, when the population has dropped to the 1937 level, the number of children under 15 will have fallen by 2½ million, and the number of persons between 15 and 65 by 1½, while the number of old people over 65 will have risen by 4 million. These figures strongly emphasise the danger of declining population which lies ahead. For this ever diminishing band of children represent the parents of the succeeding generations.[2]

(iii) It is both possible and practical to plan and control the population within certain limits, provided the population concerned agrees to do this and cooperates. The limits are, on the one hand, the potential fertility of the female population, and on the other the amount of skill necessary to use the simplest birth-control device. Even this lower limit can be still further reduced by compulsory or voluntary sterilisation.

(iv) In most people, emotional factors encourage the production and rearing of children, while economic factors discourage it. Having children in Britain is a pleasure, but for all but agricultural labourers a bad cash investment. Probably the most important factor in reducing fertility in the middle of the last century was the stoppage of child labour, which turned a large family from an economic advantage into a disadvantage.[3]

An interesting rider on this is provided by a survey undertaken in April, 1942, by the British Institute of Public Opinion. A representative cross-section of the adult population of Britain was asked "What do you think is the main reason why parents nowadays are not anxious to have larger families?"

The results were as follows:—

	%
Economic reasons (46%)	
Incomes too small for large families	26
Can educate small family better	14
Insecurity of all kinds	6
Political reasons (19%)	
War, why bring up cannon fodder?	13
Lack of faith in the future	6
Personal reasons (19%)	
Young people want freedom	12
Too much responsibility and bother	6
People have too much sense	1
Miscellaneous (9%) (including birth control, lack of state assistance, taxation)	
No comment (7%) (including those saying they do want large families)	

(v) Attempts to make children less of an economic disadvantage—but still a disadvantage—and thus to stimulate reproduction, have failed. In past times and even at present in the lower social groups, whenever children have been an economic advantage, reproduction has increased. This is, however, probably not the only factor; the lower social groups are almost certainly more careless over birth-control technique than the upper groups.

(vi) A falling population has sometimes been regarded as a good thing, because it would cure unemployment. This view is based on a fallacy. The amount of available goods and services for everybody in any community depends on the amount of work which all members of the community do. The larger the community, the more specialisation is possible, and the more there is available for all. The ultimate limiting factor is raw material, and as yet there are no signs of shortage of raw material in the world as a whole. If the size of any community decreases (other than by emigration, which is a spreading of the community rather than a reduction in its size), the amount of goods and services available decreases, and the real standard of living falls. Assuming that the organisation of the community is not changed, unemployment will in fact increase relative to the whole population. A falling population in itself will produce rather than cure unemployment. Unemployment is a sign of bad organisation rather than overpopulation.

(vii) Most reasonable people in Britain, who have thought seriously about the problem, want to see the British race (used in the loose sense to mean those who live in Britain) continue to exist at a population level which does not overcrowd these islands. What constitutes overcrowding is a debatable point. But even those who consider the present population too great agree that there is still much space in the world where people of British stock could live with pleasure and profit to themselves and their neighbours.

7. The following proposals follow inevitably from these agreed facts:

(i) After the war a long-term planned population policy is needed. It is difficult to start such a policy in war-time because the immediate need is for a large body of female labour not incapacitated by pregnancy. But from the point of view of population planning, certain war-time measures should be continued into the peace until they are replaced by something better. These are war-time nursery schools, cheap and free milk and vitamins, and school meals.

(ii) The main point of such a policy must be to make children an economic asset rather than a liability to all social classes of the population. It will be useless merely to make them *less* of a liability (e.g., by increasing income-tax children's allowances which meet *part* of the cost of children). The best ways of carrying this out appear to be:—

(a) A universal system of adequate family allowances for all non-wage earning children. The cost per year of an allowance of 10s. per child per week would be:—

For all children up to 18 years	£300,000,000
For 10% of young people aged 18–21	5,000,000
For 5% of young people aged 21–25	3,500,000
	£308,500,000

The figures given for the upper age-groups assume that 10% and 5% of the population are receiving post-secondary education—possibly an overestimate. The national income in 1941[4] was £6,338,000,000. The cost therefore of this proposal is under 1/20 of the national income. If we decide that to spend or rather redistribute 1/20 of the national income in this way is essential, the question of how the money is raised is of secondary importance. This will be discussed later, as also will the many other advantages which follow from family allowances, apart from their effect on the future of the population (¶ 17–20).

(b) *A universal system of free education, with equal opportunities for all children, and planned vocational training.*

(iii) It is only slightly less important to make children a social asset to all classes of the population. This calls for:—

(a) A planned housing policy, so that homes and their surroundings may be suitable for the happy and healthy growth of families of 3 or more children.

(b) The provision of nursery schools so that mothers who wish to carry on premarital occupations may do so.

(c) An educational campaign throughout the country to popularise families of 3 or more children. It is useless to carry out such a campaign, however, unless all the material factors working against large families have first been dealt with. It is important that commercial interests which may compete against large families should be carefully watched, and if necessary controlled. A "baby car" is an asset for the unmarried or the sterile, but if it is allowed to compete with children, it becomes a danger to a planned population policy.

(iv) Having taken steps to encourage fertility it is essential to study the results. To undertake such studies, it is suggested that a Demographic Research Department should be set up as a part of a national Social Research Council, analogous to the Medical Research Council. The results of such studies should be published.

(v) While every economic and social encouragement should be given to those who want children, the means of avoiding children should also be available to all. It is suggested that if children are a sound economic and social investment, the only people who will not wish to have them will be the feckless, the selfish, the lazy, the psychopathic—in fact precisely the group whom the eugenist would wish to see breeding least. Particularly among working-class men, the use of contraceptives is looked upon with disfavour; it is even thought to cause impotence. Education for the "3-and over" family may therefore be coupled with education in contraception. In particular, the efficacy and simplicity of modern chemical contraceptive technique needs making known to the public generally.

(vi) On the subject of compulsory sterilisation either of mentally defective adolescents on discharge from institutions for children, or of recovered psychotics on discharge from mental hospitals, we express no final opinion. Until more is known of the carriage of defective genes by normal people, and of talent-conveying genes by abnormal people, we consider that it is wiser not to rush in where experts fear to tread.

III Productive Capacity

8. It is now known that the wealth of a country is not measured by the amount of money, or even gold, that it possesses, but by the amount of goods produced and services performed by its citizens. Even imported goods are ultimately paid for by current exports, by services in the form of marine transport, or by past exports not paid for at the time by the recipients (capital investments abroad) Our national wealth, then, depends entirely upon how intelligently and how hard we work

9 In war-time, we divert a great part of our national energy and intelligence to the task of waging and winning the war We reduce our personal wealth (in the form of the goods and services we each receive) to the lowest level compatible with the efficient waging of war, and devote the surplus to the fighting services and the manufacture of munitions The limits of our war effort, as this is called, are not financial but physical We must keep our citizens physically fit for their war work, and mentally content to go on doing it Every scrap of energy and intelligence beyond that can be, and very largely is, devoted to the war effort This is brought about by a series of industrial, social, and financial manipulations —

(i) *Control of industry* —New war industries are built, and the unemployed population is given work The output of peace-time industries is fixed, so as to supply the minimal needs of the population, and no more This is done by controlling the allocation of raw material, and fixing the amount of manufactured goods produced The excess prewar productive capacity is turned over to the war effort The creation of new non-war industries is forbidden

(ii) *Rationing and price-fixing* —If no steps were taken, the greatly reduced amount of goods available for home consumption would all be bought up by the people with most money Prices would rise rapidly and shortages would be severe So the maximum amount of the essential goods each person may buy is fixed (rationing), and the prices of these and also semi-essential goods, as well as rents, are pegged at definite maxima, at the same time, subsidies may be paid to the essential restricted industries to enable them to carry on producing at the fixed prices As a result nobody can have more than his fair share or spend more than a certain amount. The surplus money in everybody's pockets is removed either forcibly (by taxation) or voluntarily (as national saving) Thus, even if one does not buy war savings but leaves one's surplus cash in the bank, the bank in fact lends it to the Government - Some people may hoard money at home This does not matter in the least, as it is not diverting energy from the war effort If, however, after the war we reverted to a free economic system, the sudden spending of this hoarded money might produce disastrous results

10. The war has taught us that finance is not a limiting factor to our efforts in any direction The limiting factors are the amounts of raw material, machinery, and labour we possess, and our power to coöperate in their use

11 At the end of the war, we may have to keep, say, half our war industries going and half our armed services in existence to act as an international police force We shall be nationally *richer* by the freed machinery and freed man power than during war-time But that wealth will be a potentiality only, unless we decide to use it If we allow our munition workers and service men to be unemployed, we shall be actually poorer. We have overcome unemployment by an enormous armament programme, analogous in some ways to a public works programme, combined with systems of control, rationing, and price-fixing. As a result, some groups of people, in particular those living on fixed incomes, are considerably worse off than they were in peace-time They will want to revert to a free economy If we allow them to have their way, we shall repeat the story of 1918 to 1939

12 More and more people (including members of the Government) consider that controls have come to stay. Our postwar industrial production will have to be planned nationally, to meet first of all the needs of the people and only then the luxuries Maximum prices will have to be fixed, and subsidies paid if necessary in essential industries Rationing of goods of which nobody buys more than they need (perishable foods, fuel, &c) can be dropped as soon as supplies are adequate to meet needs, though, in view of the needs of the occupied territories this may be some time But some form of composite rationing for clothes, hardware, furniture, and non-perishables will have to go on for a long time Unless this is done, an orgy of buying will lead first to severe shortages, and then to an orgy of production, followed by a fall of prices and a slump—with a recurrence of unemployment

13 How are needs to be determined ? How are we to decide what to produce ? First must come physical necessities —

(i) Nutritious food Science can be as dictatorial about nutritional minima in peace-time as it has been in war-time, and adequate food-supply should be an A1 priority

(ii) Adequate supplies of heat, light, potable water, sewage disposal arrangements, and fresh air These also are A1 priorities for everybody, but where alternatives are possible, public preferences must be weighed This itself is a scientific job, and the Government already has machinery for carrying out preference tests—the Wartime Social Survey of the Ministry of Information [5]

(iii) Preventive and restorative health services These again are A1 priorities With them the rest of this report is concerned While there is much discussion about how these services should be organised, there is less room for discussion in considering what the people need It must be continually remembered that finance should no longer be regarded as a limiting factor If the physical means to supply these services are available, cost is no longer an excuse for delay

(iv) Clothing necessities The war is teaching us how to distribute the minimal clothing needs fairly It is also showing how wide a variety is possible inside these minima Until all basic needs have been met, energy must not be diverted to producing variety only for variety's and profit's sake Preferences within the minimal need figures can be determined by social survey (see ii above)

(v) Housing, furniture and hardware In no field is speculative finance more disastrous than in housing To sell a bad house is to take the edge off the happiness of its successive inhabitants as long as it is inhabited Men spend long terms in prison for crimes causing far less upset to society Further, a house always has to be thought of in relation to its environment—its distance from the places of work, education, and amusement of its inhabitants, its distance from shops, its relationship to its neighbour houses The task of replanning and reconstructing the results of a century of bad building and a few years of bombing is certainly one which could occupy all surplus unemployed for many years to come But it can only be carried out if private interests are firmly dealt with, wherever they conflict with public interests The sale of shoddy furniture and hardware is hardly less of a social crime than the sale of shoddy houses As with clothing, the manufacture of excessive varieties must be prohibited until the basic needs have been met with a limited utility range

14. Mental necessities are no less important than physical necessities

(i) Adequate education This is no place to set out a plan for education If, however, one remembers that finance is no limitation, the modest proposals of educational reformers during the past 20 years should be regarded as a minimum Free education for all till 18, with the last 4 years increasingly vocational, should be combined with free university or technical training for those who can profit most from it The size of the quota entering each faculty must be determined by the national need It is equally important that the salaries of school and university teachers should be raised to a level nearer to the most lucrative profession—medicine The care of the child's mind is, one would suggest, even more important than the care of the adult's body One last word adult education is only a little less important than child education Neither need be dull—in fact, if they are dull, they are failing To everyone, throughout his or her life, food for the mind must be freely available, and nicely graded according to individual capacity.

(ii) Adequate occupation The deterioration which follows lack of occupation has been adequately enough shown in the past 20 years for even the most critical scientific observer. Optimal maximum working hours, from the point of view of efficiency and production, have been determined. We go beyond these at our peril. Equally, in the other direction, there is a minimum below which one starts to get “the cameleous hump.” The need for adequate occupation for all is merely the other side of the production story. While the essential (and even semi-essential) needs of anyone are unsatisfied, there is no excuse for a system which allows anyone to be unable to find work. We may, if we are sensible, regard refusal to work as a crime against society which deprives the refuser of the rights of the citizen. As for the person whose actions create unemployment, he must receive a little elementary education in economics and civics.

(iii) Adequate recreation. The production of recreative facilities involves the planning of parks and playing-fields, countryside and coastline, theatres and cinemas, clubs and societies, hotels and hostels, transport and communications. For everyone, the minimum must be the easy facility to enjoy all we have to enjoy in Britain—in our countryside, literature, drama, art, music, architecture, sport. Nor must we be rigidly national either in taking or giving these pleasures which life has to offer.

15. *From our consideration of the productive capacity* of the country, and in particular from the lessons we have learnt during war, the following conclusions may be drawn:—

(i) Since it has been discovered that finance, as such, is no longer a limiting factor in national endeavour, it will only be offered as an excuse for not taking action by the ignorant, the prejudiced, or the wicked. Action must be based on available real resources and priority of needs.

(ii) Available real resources will be greater after the war than during it. There is no need for a return to pre-war poverty, slumps, or unemployment, if we are prepared to impose certain disciplines on ourselves. By continuing to sacrifice some freedoms, which we have willingly sacrificed in war, we can gain greater freedoms than we possessed before.

(iii) As these facts are rapidly becoming common knowledge, it is likely that the public will choose to have a planned and controlled economy, with its corresponding social benefits.

(iv) A planned health service is an A1 priority. The best that the medical and allied professions can provide must be available for everybody. Provided this does not encroach on other A1 priorities we need not count the cost. Since the productive wealth of Britain has never been greater, we can plan if not prodigally at least boldly.

IV. Poverty

16. It is generally agreed that poverty, by which is meant lack of enough money to purchase the necessities of life, is a major cause of ill health and unhappiness. The average height and weight of the poor is considerably below that of the upper and middle classes. The infant-mortality rate and the incidence and death-rates of pulmonary tuberculosis tell the same story. The mental misery caused by poverty—and the fear of poverty—cannot be expressed statistically. The anxiety of the worker for whom unemployment or sickness means lack of food for his wife and children, the anxiety of the mother who cannot buy what she knows her children need, the anxiety of the old person who cannot exist without contributions from his or her children which are themselves producing poverty in the contributors, make up something of the mental results of poverty.

17. The immediate causes of poverty in twentieth century Britain are equally well known. They are:

(i) Unemployment of the chief wage-earner (32%).

(ii) Sickness of the chief wage-earner (9%).

(iii) Insufficient wages to meet family expenses. These expenses depend more than anything else on the number of children in the family (21%).

(iv) Old age (22%).

(v) Widowhood or unmarried motherhood, if associated with inability to work because of children (6½%).

The figures in parentheses are those of Tout,[6] based on a sample of 480 of the 11,000 Bristol families suffering from poverty in 1937. (A miscellaneous group of about 10% completes Tout's analysis.) The distribution of causes will vary to some extent from area to area.

18. *It follows that the complementary causes of poverty are*:—

(i) Inadequate unemployment insurance and assistance.

(ii) Inadequate sickness benefit.

(iii) The failure of wages to allow for the size of the family.

(iv) Inadequate old age-pensions.

(v) Inadequate widows' pensions and allowances for their children.

19. Absolute poverty causes physical ill health. *Relative poverty causes much unhappiness in the income groups outside the absolute poverty classes.* Relative poverty may afflict the family of a wage earner whose income is £1000 a year or more. He may consider it his duty to his children to send them to public schools and universities. If he has 3 sons, they may cost him, for 7–10 years, more than £600 a year. If he, or his wife, have old or sick dependent relatives, he may have to pay another £100 a year. A severe illness in the family with an operation will reduce his income by another £100. As a rule the result will be disposal of savings or debt. It follows that measures aimed at curing the ill health or unhappiness produced by poverty must be applicable to all classes if they are to be effective. Measures which exclude the upper and middle classes provide a high road *to fascism.*

20. The cure of poverty follows automatically from a study of its causes:—

(i) *There must be a national minimum wage* for both sexes which will enable its recipients to purchase all the basic needs for physical health. This, and all subsequent figures, must be initially determined and redetermined at regular intervals by the method of social survey. As immediate postwar national minimum wages, we suggest 20s. a week for children under 18, 30s. for young people between 18 and 21, and 40s. for people over 21.

(ii) To this must be added a wife's allowance where the wife is working domestically. It is illogical that the wage packet of the married and unmarried man should be the same. Equal pay for equal work is a principle deeply ingrained in the British industrial system, yet it is a principle which is seldom extended to women. In our view, equal *basic* pay for equal work, regardless of sex, should be a universal principle. But the married man with his wife employed domestically should have his pay supplemented by a *marriage allowance of, say,* 20s. per week. It would be unfair that employers should be penalised because they employ a large number of married men, or assisted because they employ a large number of single one. We therefore propose either an employers' marriage allowance fund, into which all employers pay a fixed sum for every person employed and from which they receive the money necessary to pay marriage allowances, or an extension of the state social insurance scheme hereafter described. Of these two possibilities we favour the latter, since the former might encourage employers to reduce both staff and productivity. Since, however, we consider that family allowances, adequate unemployment and sickness pay, and old age and other pensions are a much more urgent problem (indeed, marriage in the absence of children does not figure as a major cause of poverty), we shall omit any detailed consideration of marriage allowances from our social security proposals.

(iii) Family allowances for children must be introduced. These have already been briefly discussed in connexion with a population policy. Again, they must not fall as a direct burden on the employer, and a combination of social insurance and Government subsidy should operate.

(iv) Unemployment benefit, sickness benefit, and widows' pensions must be raised to the national minimum wage level. Wife's allowances, in the case of men who are out of work or sick, should continue, as also must family allowances for children in all three cases. Sickness benefit should cover injury or permanent disability, whether sustained at work, at war, or as a result of the negligence of others. It should be separated from any penal element directed towards the persons supposedly responsible for the accident or illness. It should continue until cure or death; unreasonable refusal of treatment or exploitation should, however, be penalised.

(v) Old age pensions must be raised. In view, however, of the reduced needs of old age, and of the likelihood of both partners being recipients, a figure below the national minimum wage for adults would be reasonable, and 30s. a week is suggested—for all as a right from the age of 65 onwards. The cost should be covered in the same way as the other allowances and benefits. An old person who continues to work is making a positive contribution to the wealth of the community and should not therefore be deprived of his pension or part of it.

(vi) In the case of all payments mentioned above, there must be no means test. Contributions must be made by all members of the community, and all must have similar rights. If a means test operates, or if there is any deviation from the minimum rights, the thrifty and industrious will be penalised, and relative poverty will continue to cause misery among those who have done least to deserve it.

(vii) A comprehensive system for the removal of poverty will only work in a community with a high level of production. There will be no room for idlers, slackers, and drones. So far from there being any large volume of unemployment, it may be necessary to penalise anyone who refuses to work. In the past, organised labour has demanded "the right to work." In the future, a system of social security will carry with it "the duty to work." The war is showing that the best method of dealing with the slacker or the absentee is by a committee of his or her fellow workers. We suggest that this system is capable of universal application. Furthermore, we consider that the best method of dealing with the neurotic or psychopath who seeks to exploit the health insurance system is for the patient and doctor both to give evidence before a workers' committee. We think that such committees are likely to arrive at common-sense conclusions which will carry much more weight with the patients than the most highly qualified medical tribunals.

The details of the organisation and finance of this social security scheme for the abolition of poverty will be discussed later (¶ 38–56).

21. We recognise that such comprehensive proposals carry with them a theoretical risk of excessive pampering and paternalism. These dangers have been put forward as an argument against most social reforms in the past hundred years; yet the same people who have put them forward, have often argued that a leisured class, existing on unearned income, is a cultural and social necessity. We consider that the conduct of British people in all social classes in the present war suggests that the virtues of courage, enterprise, and vigour (and indeed a certain number of vices) occur independently of the income level and the measure of financial security. We regard the theoretical risks involved in social security as well worth running.

V. Purchasing Power

22. Our present system of medical practice depends largely on the way the national purchasing power is distributed. Most wage earners contribute compulsorily to an insurance scheme which enables them to pay for medical attention during the time when they can best afford it—that is, when they do not need it. The dependants of the insured population, having individually small purchasing powers, pay small fees for the medical care they receive. The middle and upper income groups, a relatively small part of the population, have a much greater purchasing power. In return for larger—and indeed sometimes very large—payments, they receive slightly better medical attention. This Robin Hood system as it has been called has a certain rough and ready justice about it. But it will only work as long as the doctors who treat the poor at low rates are able to make up by treating the rich at high rates. If the rich lose their purchasing power, the doctors who depend mostly upon them (but who serve all classes) will be driven out of business. It so happens that this particular group of doctors—the consultant and specialist group—is of vital importance in the chain of curative medicine.

23. Purchasing power is, as it were, the mirror image of productive capacity. A nation can buy only what there is to have in the way of goods and services. If the amount of money available is pushed up beyond the productive capacity, purchasing power does not increase; instead the value of the money goes down. Sometimes the economic machine gets out of gear and the available goods and services exceed purchasing power. Unless purchasing power is then increased by the issue of new money, the value of the goods and services in terms of money falls and a slump sets in. It is extremely probable that in our post war economy, the Treasury and the Bank of England will see to it that purchasing power keeps strictly in step with productive capacity. It is equally probable that our productive capacity will be greater after the war than it is during it. The total national purchasing power will, therefore, increase. The important point to consider is how will that increase be distributed.

24. Broadly speaking, there are three possibilities:—

(i) Everyone will be richer.
(ii) The poorer will be richer, and the richer the same.
(iii) The poorer will be richer and the richer will be poorer.

There is a fourth theoretical possibility—namely, that the poorer will be poorer still and the richer enormously richer. This can be ruled out, as even if such a situation were to arise temporarily, strikes and labour troubles would rapidly reduce productive capacity and consequently the enormous riches of the rich.

25. We may regard it as reasonably certain that the poor will be richer. The real problem is what is likely to happen to the richer section of the community. The only answer we can give is to study the fate of the rich in a planned and controlled economy. The essence of sound planning is that necessities for all should precede luxuries for any. This will probably be achieved by a combination of:—

(i) Planned production, based on scientific assessment and social survey.
(ii) Controlled prices, with subsidisation if necessary.
(iii) Rationing of essentials in short supply.
(iv) Raising the purchasing power of the poor by:
  (*a*) Minimum living wages.
  (*b*) Family allowances.
(v) Controlled national finance, so that national purchasing power keeps in step with production.

26. There must obviously be considerable Government intervention in the industrial structure. Since the inherent value of national ownership is disputed, it will be more profitable to consider first the minimum amount of intervention necessary for a planned economy. If production is to be planned, the Government must decide what is to be made. It can, however, leave the making to private enterprise, though Government specification and inspection are desirable. If price control involves subsidy, as is now the case in the food industry, Government wholesale and distributing organisations are desirable if not essential. The control of national finance must aim at the issue of new money to supply the purchasing power for the results of new production, but must limit this issue so that inflation does not occur. If all prices are controlled and rationing covers all goods in short supply, the production of an excess of new money is quite harmless. It cannot be used to force up prices, or to deprive anyone of their needs. Its possessor is unable to spend it, and so either it is hoarded, or it is lent to the Government or to private organisations (banks or

companies) for new capital development We have postulated a condition where new capital development (i e , new industrial production) is controlled by the Government, so that an influx of new money will not lead to mushroom industries In a completely controlled economy, then, inflation is not a danger It will, however, be a very real danger if price control and rationing are half hearted The other important aspect of national finance is the imparting of purchasing power to the Government (supplying the national revenue) for carrying out all its works In a controlled economy, the methods which have proved successful in war-time would be equally successful Up to, and indeed over, half the revenue needed to supply the Government needs can be met by borrowing surplus profits and salaries from the public Some of this borrowing will be from individuals, but most of it will be from banks, corporations, and industrial concerns The rest of the Government's need will be met by direct and indirect taxation Though defence expenditure will be considerably smaller, social expenditure will be considerably greater So we can look forward to taxation continuing at a high level

27 Since a planned economy does not necessarily involve the abolition of private capital ownership, nor the imposition of taxes heavier than war-time taxes, there is no purely economic reason why the rich should not continue to have approximately the same incomes as in war time They are unlikely, however, to go back to peace time incomes, if only because the Government will continue to be a heavy borrower and will try to keep interest rates low Further, in a controlled economy, the opportunities for profit by speculation on the stock market will be decreased

28. There may, however, be political reasons why the incomes of the rich should decline If widespread nationalisation of essential industries takes place, compensation of owners will probably be with bonds carrying a low interest rate Further, the economic need for a rich capital-owning class will disappear, and political pressure against the unnecessarily rich will have sound economic backing Heavier taxation of high incomes will be practical, and may be thought desirable If this sequence of events takes place, the rich will be definitely poorer in a post-war society

29. *From the point of view of medical planning*, we must have a flexible system, capable of providing the whole community with everything medical that it needs, but also allowing the rich to pay more if they want to Under no circumstances are we justified in saying that the rich shall get better treatment than the rest, because they want to pay for it Only the best must be available for everybody

VI Distribution of Population and Reconstruction of Town and Countryside

30 In the past, the distribution of population has been uncontrolled by conscious planning It has not, of course, been fortuitous Industries have developed around raw materials or in suitable climates, and men have followed them Commerce has centred on good harbours Market towns have sprung up in agricultural districts In the past 20 years, a large part of the population has moved south away from the declining heavy industries to the new light industries But it has all been unplanned unplanned for strategic safety, industrial efficiency, transport of products, transport of labour to and from work, community life, and health and happiness of the workers, the managers, and the families of both The result is the most disastrous urban development in Europe The undoing of the work of the nineteenth century and the first forty years of the twentieth is the biggest task which will face the people of this country after the war

31 It is no part of our purpose to discuss town and country planning, except in so far as it affects the physical and mental health of the people With these in mind, we can lay down a series of elementary criteria which must be fulfilled in all new developments —

(i) There must be adequate accommodation for

(*a*) People who wish to (or have to) live by themselves (probably mainly in flats, flatlets, hostels, or lodgings)
(*b*) Married couples with no children, or very young children (probably mainly in flats)
(*c*) Married couples with children over 2 years (probably mainly in houses with gardens)
(*d*) Older married couples, whose children have left home (probably mainly in flats)
(*e*) The elderly and aged, widows and widowers (in part-service flats or cottages)

The proportions in each group, and the proportions within each group wishing different types of accommodation can be determined for each community by social survey methods

(ii) Workers must be housed within easy travelling distance of their work Every hour spent in travelling to work, and every gallon of petrol, is a waste of national productive capacity—that is, of the national wealth. Furthermore, by lengthening the working day, and by spreading droplet infection, it is endangering the national health

(iii) Everyone must be housed within easy travelling distance of the real countryside This means smaller cities, no ribbon development, and no suburbia

(iv) Families must be housed near schools, shopping centres, theatres, libraries, and clubs

(v) Rooms must be light, sunny, well-ventilated, warm, and sound-proof There must be an adequate choice for those who like small or large rooms, small or large windows No-one and no family should be condemned to live in the boxes which pass for rooms in many modern flats—unless they wish so to do There should no longer be an excuse for inefficient heating when gas, electricity, and piped industrial waste steam (as *installed in Detroit and the new Russian cities*) are universally practical

(vi) Every family must have its own lavatory, bath, wash-basin, and kitchen with sink

(vii) Labour-saving devices must be available to every housewife

(viii) Flat-dwellers living more than two floors off the ground must have lifts

(ix) The outside of every building must be planned for beauty and harmony, in keeping with its environment

32. There can be few people who would dispute the desirability of these criteria There are no physical difficulties *in converting them from paper to reality* The difficulties which stand in the way are our own selfishness, whether we be building society members, tenants, landlords, rate payers, or members of local or *national government Each of us has interests which* might suffer temporarily if thoroughgoing physical reconstruction were put in hand But each of us, equally, has far more to gain if we are prepared to take a long term view and act on it

33 Piecemeal remedies have been tried and have failed Radical cure is now necessary, and it calls for as much ruthlessness as did the first radical mastectomy All land and buildings will have to pass into the ownership, or at least full control, of the state , a possible mechanism would be a national land corporation with *the present inhabitants* becoming the state's tenants and the present owners receiving compensation Such a national land corporation would have to plan all development, urban and rural, industrial and agricultural, on a *regional basis Socially inefficient property* will, in due course, have to be destroyed as ruthlessly as the sanitarily condemned The scale of demolition will have to be enormous But if we can bring ourselves to the task, we have before us *the opportunity to* add to the world's loveliest countryside the world's finest towns

PART II

Paying For It

VII Present Methods of Payment

34. It is agreed that the best possible health services, both curative and preventive, shall be available to everyone. It is agreed that the nation as a whole can afford to pay for these services. It is also agreed that lack of capacity to pay shall not deprive anyone of the best. The major problem which must now be considered is how shall the total cost of these services be borne by the community. Before considering the amount of payment, method of payment will be discussed. At the present time money is withdrawn from the community for this purpose in different ways:

(i) By the direct payment of doctor's and nurse's fees, and contributions towards hospital costs. Often the fees extracted are below the market value of the services rendered. This is counterbalanced by the fees charged to better-off patients which are above the market value of the services.

(ii) By insurance payments, made by patients when they are well, patients' employers, and the state, which reach the doctor as capitation fees. The state's contribution is derived from general taxation, direct and indirect, which falls on doctors and patients alike.

(iii) By rates, supplemented by state block grant (again from direct and indirect taxation) which pay for environmental health services, the work of medical officers of health both environmental and clinical, and the municipal hospital services.

(iv) By private contributions to hospitals and other insurances (hospital savings associations, the "Public Medical Service," &c.), and by charitable gifts to hospitals.

(v) By miscellaneous forced contributions from employers (workmen's compensation) and guilty parties in *accidents* (or their insurance companies), and other minor sources.

(vi) By direct payment out of state funds, to provide the Emergency Medical Service.

35. In favour of these mixed methods it is urged that they encourage efficiency through freedom of choice, as well as individuality. Against them it is urged that they are unjust, inefficient, and unnecessarily costly. It is fair to say that those who favour the present mixed methods usually couple this with the advocacy of additional direct state contributions to the particular type of organisation with which they are associated.

36. If we examine each of these methods of payment, we find substantial agreement on the following points:

(i) The *direct payment of fees*, whether these cover costs or are a contribution to cost, falls on the patient when he or she can least afford it. Even among the small proportion of the population with incomes of over £1000 a year (before the war, approximately 1·5% of the total incomes), surgeon's bills and nursing-home fees add to the anxieties of illness.

(ii) The direct payment system retains a certain measure of popularity both among doctors and patients, for the following reasons:—

(*a*) It gives doctors a sense of dependence on themselves and their own abilities, and of independence from the state or any wage or salary paying organisation.

(*b*) It makes doctors feel that the harder they work and the greater their skill, the more they earn.

(*c*) Many also feel that the abolition of the direct payment system would substantially reduce their incomes.

(*d*) It gives patients who can afford it a sense of satisfaction and independence at being able to purchase medical aid with as little interference as they purchase a suit of clothes.

(iii) The sense of independence both among doctors and patients is a healthy phenomenon. It is, however, retained to a large extent under the panel system as also is the *relationship between amount of earnings and amount of work*.

(iv) The *panel or insurance* system has the serious disadvantage that it does not cover the dependants of wage-earners, or the upper and middle income groups, nor does it provide specialist or institutional treatment for its subscribers. These are defects of scope rather than inherent defects. On the other side, it has much to its credit:—

(*a*) Though the "free choice of doctor" is largely illusory, nevertheless it is felt by both doctors and patients to exist. The knowledge that patients *may* leave, if they wish, helps to keep the less conscientious doctor up to scratch. From the patient's point of view, a doctor—or a hospital—chosen, or felt to be chosen, is likely to excite greater faith than one imposed. It is worth pointing out that initial freedom of choice is much less important than freedom to change later. "You don't know a rotten apple till you've bit it."

(*b*) The actual weekly payments by the patient are a strong factor in retaining self-respect. The panel is not a free service but a mutual benefit arrangement, in which services received do bear a relation to payments made.

(*c*) The panel does succeed in allowing the cost of sickness to be borne during the time that the patient is fit.

(v) The main disadvantages of the panel system (apart from its limited scope already mentioned) are:

(*a*) By levying a contribution from employers, it acts as a tax on industry, and acts in some measure as a deterrent to industrial expansion.

(*b*) The cash and other benefits given by the different approved societies are extremely unequal and the sickness benefit in no way approximates to a living wage.

(*c*) Approved societies have been found to be as wasteful a method of administering public funds as any yet devised. In the period 1934–37 the Ministry of Pensions scheme distributed £42 million, at a cost of £0·75 million. The various societies and insurance companies had the following record:

	Benefits distributed (*million*)	Administrative costs (*million*)
NHI	£33	£6
Workmen's compensation	£9	£4
Industrial insurance	£33·5	£22

(*d*) The approved society collectors are presented by the state with a right of entry, and consequently an opportunity for touting, in every working-class household.

(vi) *Rates* as a method of payment for any service have little to commend them. In their favour, it is stated that they serve to stimulate local interest in local government, and they have the advantage of familiarity. The case against them is as follows:

(*a*) The richer a community, the more it can afford to pay in rates, but the less it needs the services which the rates supply. Conversely, the poorer a community, the less it can afford to pay in rates, but the more does it need the rate-paid services. Rates, then, are a basically unfair form of community taxation.

(*b*) Rates are based on the value of the home or property, and are roughly proportional to the rent. The poorer the person, the greater the proportion of his income which goes in rent, and consequently the greater the proportion which goes in rates. Further, the larger the family, the larger the house, and consequently the larger the rates. Rates, then, are also a basically unfair form of individual taxation.

(*c*) If a property is improved, its rateable value is increased. Hence, rates are a tax on enterprise, and inhibitors of improvement in environmental conditions.

The central government has attempted to mitigate the evils of rates, in peace-time, and to a greater extent in war-time, by the system of block grants out of national funds. These have enabled some poor communities to have certain necessary services which they would not otherwise have been able to afford. But the essential injustices of rates remain.

(vii) *National taxation* and *national credit* are the most efficient sources. The *income-tax*, in spite of its unpleasant associations and some technical deficiencies, is the fairest method of taxation so far devised. Deduction at source was a great advance. Its only substantial disadvantage is the lack of connexion in the mind of the payer between his contribution and the services he receives in return The super-tax and death duties are merely an extension of the income-tax principle Indirect taxation—purchase tax, customs duties, &c —should be regarded rather as a method of restricting consumption than as a source of revenue In the interest of good citizenship, indirect taxation should be avoided altogether as a source of revenue In a democratically mature society, the tax-payer should be clearly aware of how much tax he is paying National credit provides the Chancellor of the Exchequer with a convenient method of controlling the national income to the national advantage

(viii) *Private insurance arrangements,* either in the form of hospital savings associations or private companies offering health insurance are costly in collection, of varying degrees of efficiency, and usually cover only *part* of the cost of treatment received—often to the distress of the patient when he discovers this

(ix) *Workmen's compensation* is an attempt to saddle employers with the cost of maintaining employees suffering from the effects of occupational accidents In fact, employers insure themselves to cover the risks they run, and compensation often operates against the interest of the workman it aims to help Its whole emphasis is on cash compensation rather than recovery At present, the only substantial gainers are the insurance companies In any complete system of health insurance, workman's compensation would be unnecessary The employer who neglects safety devices—or the motorist who drives to the danger of the public—should be dealt with by the ordinary processes of the law

(x) *Charitable contributions* are quite inadequate to maintain any complete health service As a major source of income they have the following disadvantages

(*a*) Contributors often give most generously to those institutions which have prominent sites—and are forgetful of those situated in poor parts of our cities, or in rural areas

(*b*) Sentiment rather than reason often induces contributions The blind, children, and animals are widely supported, the chronic sick, the senile, and the neurotic seldom

(*c*) Givers of large gifts often prefer to erect new buildings rather than to endow existing ones Yet in all enterprises, it is the people who work in the buildings rather than the buildings themselves which matter

To these practical disadvantages, it is sometimes added that the flavour of charity is repugnant to its recipients, and damaging to its dispensers The evidence on these points is strongly charged with emotion We, however, do not feel strongly If rich people continue to exist, and if rich or poor wish to make gifts towards the cost of the national health services, we think these should be gracefully and gratefully received But the giving of gifts should confer no rights on the donor, indeed, a gift which conveys a right bears little relation to charity, at any rate in the Christian sense The sale of the office of governor of an institution, in return for a contribution of a minimum size, should be discontinued

37 As a rider on the present situation, the following example from the practice of a North country GP may be quoted —

> "I have one family who is attended under the following heads the father is an NHI patient, the mother has always been a private patient and prefers this, the children are attended under the Public Medical Service (the parents felt they could not afford bills for the probable bouts of infectious illnesses), and there is an old man in the same house attending under an old club scheme (the Free Gardeners) All patients in this variegated collection actually get the same attention The children are examined at school and sometimes get advice at the school clinic (until recently no note of this was ever sent to me), they also get dental and ophthalmic treatment through the school The father's approved society is "broke," so he and the mother have to pay for their own dental and ophthalmic treatment The old man is toothless and has been for a long time, and does not care for reading, so this problem does not worry him The family subscribes to the two local voluntary hospitals, but if any of them have skin complaints, they have to go to the municipal hospital, as neither voluntary takes skin cases The father also subscribes to an ophthalmic hospital outside the town and an hospital in London, this is quite unnecessary as local voluntary hospitals have efficient ophthalm orthopædic departments

VIII Paying in the Future

38. The ideal method of payment should hav following characteristics —

(i) Members of the public should have the feelin they are themselves paying for the services they re and they should have a measure of freedom in ch who shall give them these services

(ii) Doctors should retain, as far as possible, the of dependence on their own efforts, and of indepe in their relationship with the state

(iii) All classes should be able to pay for services they are well, and should be freed from the bur payment during and after illness

(iv) Payments made during times of health cover all services needed at any time

(v) There should be no question of persons wis pay private fees at the time of illness receiving pr tial treatment over patients being treated on an ins basis

(vi) At the same time, some people in the upper groups do wish to continue private contract for treatment It should be possible for such people out of a part of any national insurance payment, cease to be entitled to medical benefits

(vii) The amount of insurance payments should b on capacity to pay—i e, on some income assessme

(viii) The burden of health services should be re from the rates

(ix) The nature of the payment should be as and as comprehensive as possible

(x) There should be no levy on employers or other isolated section of the community

39 It is therefore proposed that every wage salary earner, or person in receipt of any form of or unearned income, should compulsorily pay a *social security insurance contribution.* In return h should be provided with —

(i) Complete treatment for all forms of sickness, ining in ing rehabilitation and if necessary tra ributor occupation, until recovery, for the contr to cho his dependants, the contributor to be free £500 own home doctor Persons earning over ontrib should be permitted to opt out of ⅛ of their co nefit being then no longer entitled to medical be res

(ii) Provision of specific prophylactic measu ch contributor and all his dependants, as well as su and supervision as is necessary to maintain health

(iii) Adequate cash sickness benefit for the con until he or she returns to work A provisiona would be £2 a week for a single man or woman, whose wife is employed, and £3 a week for a marr whose wife is occupied domestically Adequate allowances would make additional payments for unnecessary, though maternity benefit should co and should be supplemented by benefits in kin discourage the unnecessary use of hospitals and tions, patients should contribute from their cash s benefit the cost of their home maintenance, say or 10*s* a week Safeguards against abuse discussed later (¶ 49–56)

(iv) Adequate cash unemployment benefit, same scale as sickness benefit

(v) Adequate old-age pensions, and pensio widows on a similar scale

(vi) Burial allowances of £20 to the nearest of all persons dying There is much to be said nationally owned and operated funeral, cemeter crematorial service, at the least, drastic of existing services should be introduced

(vii) Adequate family allowances, at a minimu of 10*s* a week for every child who is not earning, inc orphans

40 In no circumstances should means tests o Otherwise the scheme ceases to be an insuranc becomes instead a state dole Further, a mean

discourages thrift and individual enterprise, and it transfers the burdens which insurance schemes seek to avoid to the shoulders of others who may themselves then be reduced to the poverty level Only by such a complete social security insurance scheme will the evil effects of poverty on mental and physical health be abolished At the same time, there should be an upward operating "Needs Test," to permit supplementary or extraordinary payments in special circumstances

41 It is proposed that payments should be graded according to incomes A basis for such grading is provided by the Ministry of Labour's family budget survey[8] of 1937–38 —

(i) In 8905 industrial and commercial working-class households, averaging 3 77 persons per household, the average total weekly expenditure was 85*s* Of this, the following figures were relevant to the present inquiry

	s	*d*	% of total expenditure
Doctor, dentist, nursing, medicine, &c	1	8	2 0
National health, pensions, and unemployment insurance	2	0¾	2 4
Other insurances and pension funds (excluding trade union subscriptions)	2	4½	2 8
	6	1¼	7 2

(ii) In 1491 agricultural working-class households, averaging 3 79 persons per household, the average total weekly expenditure was 57*s* 4*d* The comparative figures with those given above are —

	s	*d*	% of total expenditure
Doctor, dentist, nursing, medicines, hospital funds, &c	1	2½	2 1
National health, pensions, and unemployment insurance	1	7¾	2 9
Other insurances and pension funds (excluding trade union subscriptions)	1	5¼	2 5
	4	3½	7 5

(iii) One other cost in these family budgets would in fact be covered by a social security payment—namely, that portion of the rates which covers municipal health services, poor relief, and education The average payment in the industrial group on "rents plus rates" was 10*s* 8*d* (12 5%) In the agricultural group it was 4*s* 9*d* (8 3%)

The Bristol Social Survey[9] shows that the average breakdown of the 10*s* 8*d* "rent plus rates" figure is 2*s* 4*d* ordinary rate, 4*d* water rate, and 8*s* rent From the figures given in the annual report of the Ministry of Health for 1938–39,[10] it can be calculated that of the 2*s* 4*d* ordinary rate, 3*d* goes towards local authority health services and 3*d* towards poor relief Thus an additional payment of 6*d* a week (or 0 6%) can be added to figure for health and insurance expenditure in the industrial group Assuming that a similar percentage of agricultural expenditures is disposed of thus, the total percentage figures are —

	%
Industrial	7 8
Agricultural	8 1

42 We can assume therefore that a social security insurance contribution not exceeding 8% of the income would not impose an appreciably greater burden on the wage earner than the present arrangement Since however it would give greatly increased benefits including family allowances, a payment approximating to 10% would probably be accepted Such contributions should be free from income tax

43 Bearing in mind that the smaller the total income, the greater is the burden of a percentage payment, the following rates of payment are proposed

Income level per week £	*s*	*d*	£	*s*	*d*	Payment per week *s*	*d*
1	0	0—	1	9	11	1	6
1	10	0—	1	19	11	2	6
2	0	0—	2	19	11	3	9
3	0	0—	3	19	11	6	0
4	0	0—	4	19	11	8	0
5	0	0—	5	19	11	10	0

Income level per year £	£	*s*	*d*	Payment per quarter £	*s*	*d*
300—	349	19	11	7	8	0
350—	399	19	11	8	15	0
400—	499	19	11	10	0	0
500—	749	19	11	12	10	0
750—	999	19	11	16	5	0
£1000 upwards a year				25	0	0

44 Each individual should decide whether he wishes to make his payments weekly, monthly or quarterly Changes in methods of payments should be allowed only once a year It should be possible for anyone wishing so to do to increase his contributions by a set percentage, say 25%, and in return to receive an extra degree of privacy when undergoing institutional treatment and exemption from clinical demonstration Similarly a voluntary increase in contributions of 25%, 50% or more should entitle the contributor to correspondingly increased benefits and pensions People with existing private insurance arrangements should be allowed to transfer their policies to the National Social Security fund, if they wish to incorporate existing premiums into social security premiums

45 Payments should be made by the purchase of stamps The stamps should indicate clearly the nature of the transaction, thus, they should bear the words "Social Security Insurance—Health—Unemployment—Old age—Family" New stamp books should be issued annually, on receipt of the previous book fully stamped, and certified correct by the employer Different coloured stamps would be issued free during periods of sickness or unemployment to show that the holder was excused payment Benefits should only be issued on production of the book fully stamped to date, the one exception to this would be medical emergency benefit In the front portion of the book, or (in view of the secrecy with which many people like to surround their incomes) in a separate book, should be a space in which the employer should enter the amount of wages or salary at the time of payment, those living by fees or income from other sources should enter the figures themselves, false entries to be punished by heavy penalties When the stamps were purchased, this statement of current income should always be produced

46 The funds thus collected should be handled by a statutory National Social Security Board, similar to the present Assistance Board, whose work, funds, offices and staff it should take over It would also absorb the Ministry of Labour's department for unemployment insurance, the pension and insurance work of the Ministries of Health and Pensions, and the work of the approved societies The minister responsible for the policy of the board in its broadcast outline should be the Minister of Health He should, however, have no control of or responsibility for day-to day working As soon as possible, the Social Security Board should open offices throughout the country, as widely diffused as post offices, Assistance Board offices would provide a nucleus for these The offices should both sell stamps and issue cash benefits Pending their establishment, both these functions should be performed by post offices

47. Unemployed persons seeking benefit should require to have their income records stamped at employment exchanges or bureaux For the sick, medical certificates would be required For family allowances and old-age pensions, birth certificates would be required in the first instance

48 We attach great importance to the type of officer in charge of such Social Security offices Such officers should be, as far as possible, trained social workers Anything smacking of poor relief public assistance, or the dole, should be got rid of The atmosphere should be that of a people's bank or a mutual insurance office, where, in addition, the complexities which confuse the

(iv) Income-tax is, in fact, even more fair than the graded payments proposed as its rise is gradual and not in a series of steps

58 Against the proposal, we set the following —

(i) The unpopularity of income-tax arises in part from the elaborate machinery devised to make it completely fair It is only by payment on one's previous year's earnings that the individual obtains maximum allowances Our proposal of current weekly payments, fluctuating with current earnings, is likely to be more welcome to the wage-earning public

(ii) The mere fact that payments were made *to* the same place *from* which benefits are received would have great educative importance We think that money paid into the National Exchequer pool, no matter how much educative publicity there is, will never be as closely linked with benefits received as under a more direct national insurance arrangement

(iii) If the health and security funds are to be derived entirely from the Exchequer, the dangers of Treasury control will be greatly increased The universities have not lost their autonomy by deriving two-thirds of their income from the Exchequer The assistance board, on the other hand, is virtually a part of the civil service

For these reasons, we reject the alternative proposal of a specific addition to income tax payments

IX The Balance-sheet

59 The national balance sheet for the health and social security services must be largely an affair of estimates for no exact figures are available for many of the items It is easier to estimate the volume of financial disbursements under a revised social security service than the cost of an adequate medical service The assumptions on which the latter are based are as follows —

(i) There will be no great change in the *average* untaxed incomes of doctors

(ii) There will be a considerable increase in the *average* rates of pay of nurses

(iii) There will be a very considerable capital expenditure on new hospital and institutional construction

(iv) There will be a reduction in all running and administrative costs as a result of large scale planning and organisation

60 The balance sheet given consists of five parts —

(i) The approximate total cost of the medical services, excluding the environmental health services, such as housing, water-supply, and sewage, in the year 1938-39 (about £160 million)

(ii) The total cash disbursements for sickness in the same period (about £43 million)

(iii) The cost of unemployment and other social relief services in the same period

(iv) The estimated cost of a complete medical and social security service as described previously

(v) The yield of the measures proposed to meet this cost

(i) *Present annual cost of the medical services* (1938-39)

	£ million
Voluntary Services	
Hospitals	17
Convalescent homes	2 2
Homes for chronic sick	3
District and other nurses	2
Other voluntary institutions and services	1 8
	23 3
Municipal Services	
General hospitals	7 5
Fever hospitals	4 2
Tuberculosis services	4 8
Mental hospitals and mental deficiency institutions	14 5
Venereal services	5
Maternity and child welfare services	4
School medical service	5
Poor law medical service	8
Other services	3 5
	52
Doctors' fees and salaries	
National health insurance payments	8
Salaries (apart from those paid by hospitals)	2
Private fees	38
	48
Dentists' fees and salaries	10
Masseurs' fees and salaries	2
Patent medicines	20
Dispensed medicines	5
	37
	160 3

(ii) *Present annual cash disbursements for sickness* (1938-39)

	£ million
National health insurance benefits	18
National health administrative costs	6
Workmen's compensation payments	12
Private sickness insurance	7
	43
Total annual health bill (excluding purely environmental services)	203 3

(iii) *Present annual cash disbursements for unemployment and other social relief services* (1938-39)

	£ million
Unemployment insurance	62
Unemployment assistance	36
Public assistance	46
Widows', orphans and old age contributory pensions	49
Non contributory old age pensions	48
	241
Total annual "social security" bill (including health)	444 3

(iv) *Estimated annual cost of proposed national medical services*

	£ million
Present cost	160 3
Additional cost of nursing services	40
Additional capital expenditure on new building	40
Saving due to large scale buying and improved administration	less 10
	230 3

Estimated annual cost of proposed social security services

Sickness benefit (assuming no change in amount of sickness)	82 5
Unemployment benefit (assuming 500,000 unemployed and ⅔ of them married)	70
Old age and widow's pensions (assuming 3 5 million old people over 65 and 0 75 million widows)	351
Family allowances	308 5
Burial allowances (assuming £20 per head for 500,000)	10
	822
Proposed annual total health and social security bill	1052 3

(v) *Estimated annual yield of proposed social security contributions*

Weekly wage	Weekly contribution	Persons	Total of contributions
£ s d £ s d	s d		£
1 0 0—1 9 11	1 6	1,734,600	6,764,940
1 10 0—1 19 11	2 6	2,649,400	17,221,100

4 0 0—4 19 11	8 0	599,600	12,471,680
5 0 0—5 19 11	10 0	900,000	23,400,000

simpler citizen in the modern world can be straightened out They should also be centres of local social intelligence, both collecting and giving out information They would thus serve to keep the board in touch with the problems of the public, and the public informed of the services available

49 The board should be administered on a regional basis Local advisory committees in each local authority area, with representatives of local authorities, local political parties, trade unions, and other groups, would form a further link between the board and its public These committees might well play an important part in arbitrating on doubtful cases, whether unemployed or sick The committee might, however, delegate its functions in this respect to a small arbitration tribunal of 3, a chairman and a workers representative from the committee and representative of the Social Security Board Such an arrangement has worked well in the organisation of the Assistance Board

50 The *method of arbitration* proposed would be substantially the same whether the doubtful recipient was unemployed or alleged to be sick If he persistently refused to work in spite of the offer of work, or continued to simulate ill health when in fact he was fit, the employment exchange manager or the doctor in whose care he was, should notify the Social Security Board officer He or she would investigate the social circumstances, if necessary by a home visit, and should then bring him before his local tribunal In a medical case, a medical assessor should assist the tribunal, which should be furnished with a medical report from the patient's doctor The worker going before the tribunal should be permitted to take a representative to speak for him The tribunal should have before it a report from the employment exchange, the previous employer, and the social worker of the Social Security Board In medical cases, a medical report would replace the first two The tribunal would not have the power to reduce benefits (as these are intended to be based on the cost of living) Its power would be to give a *direction* as to work Failure on a worker's part to follow such a direction to work would render him liable to be brought before a county court or a stipendiary magistrate's court, and punished Such punishment would automatically deprive the recipient of his benefits, leaving, however, his dependants unaffected The worker's refusal to work would thus constitute an appeal to a legal authority who would have to hear both his case and the case of the tribunal An official of the Social Security Board wishing to mitigate a ruling of a tribunal should be able to appeal to his or her regional chief

51 The position of the partially disabled person has still to be considered The completely disabled person will be adequately covered by the sickness benefits of the Social Security service Partial disablement may arise from illness (e g , tuberculosis, cardiac disease, arthritis), or accident (on the road, in the home, at work, or in the Forces) At present financial assistance for partial disablement bears little or no relation to needs Its source may be from a Service pension, an employer's or a motorist's insurance policy, the pocket of a private individual against whom damages are given in the courts, or public assistance Victims of accident are, as a rule, in a better position than victims of disease The aim of the Social Security service must be to maintain the patient and his family until he is fit for work The aim of a national medical service must be to make every patient, whether sick or injured, fit for work But there will still be a certain number of patients, fit for light or special work on short hours, who will never be able to take up their old occupations

52 The social problem presented is that of training and placing in suitable work, a task which might well be linked with that of physical rehabilitation The disputed question of the special colony or settlement as opposed to the open field of labour will be considered in a later section The monetary problem, we propose, should be solved in the following manner

53 If the worker's salary in his new occupation is less than his previous salary, it should be supplemented by a grant, its amount being the difference between his old salary and his new one, with, however, a maximum grant of the total of full weekly sickness benefit At the end of a year his position should be reviewed, both as to degree of any further recovery and amount of grant—the same principles as before being applied, after allowing for any increase in salary which may have occurred Thereafter the grant should be stabilised, so that further increments in salary may lead to a true increment in earning The partially disabled worker will thus be helped over the difficult transitional period, and once the grant has been stabilised, he will have a financial incentive to become a productive and useful citizen

54 The risk of exploitation by the compensation hysteric will still exist, but a properly organised rehabilitation service, including a psychiatric rehabilitation service, should greatly reduce this It is, however, important that justice should be done to every genuinely disabled and partially disabled person, even if a certain number of hysterics gain thereby Incidentally, the recurrent prospect of the physically fit hysteric appearing before a tribunal of his social peers is likely to have a healthy deterrent effect

55 An examination of these proposals reveals a number of advantages —

(i) Sickness would have no advantage over unemployment as a source of income So if a person had no work waiting for him, continued sickness would have no cash incentive

(ii) The criterion for action would be in all cases refusal to work when physically fit

(iii) The decision would be taken by a committee or tribunal of the workers own peers, and as such would be more likely to be generally accepted than any that a medical or legal panel might make Tribunals would rapidly acquire skill in identifying scrimshankers At the worst, when a worker had appeared before them on two or three occasions persistently refusing to work, they would begin to see through him

(iv) The whole of workmen's compensation, with its burdens on employers, its injustices to workers, and its openings for exploitation, would lapse

(v) The whole of public assistance, poor relief, and unemployment assistance, with its social stigma of the dole, charity, and the rates, would vanish

56 In practice, at the end of this process, there would remain a small body of men and women, probably mostly psychopathic, who preferred gaol to work, at present termed unemployables or tramps It is a difficult matter to decide whether these should be coerced into colonies where they may contribute at least some labour towards their cost to the community, or should be allowed to pursue their way around the country from casual ward to casual ward Since we believe in the liberty of the subject—even to the " hobo "—we favour the continuance of a limited number of casual wards, supported not from the rates but from Social Security Board funds

57 Before closing this account of our proposals for paying for health and social security, we must mention an alternative method which has been suggested—namely, a specific addition to everybody's income tax payments In favour of this, it is pointed out that —

(i) The machinery of collection already exists , to build up a duplicate machine is unnecessary

(ii) Deduction at source reduces to some extent the pain experienced in direct tax payments

(iii) While the odium which surrounds the income-tax is admitted, our aim should be rather to clarify in the public mind the link between tax payments and services received, than to construct an alternative to avoid that odium

71 The pull between the technician and the administrator is strikingly illustrated in the civil service. In the Ministry of Health, the doctors and engineers have remained ultimately subordinate to the pure administrators. Similarly, in municipal hospitals, clinicians are subordinate to administrators, though often these administrators have previously been clinicians. For this reason, the best technicians have often refused to serve in such organisations, and those who have served have become frustrated and disillusioned. We think that the answer to this problem is to be found in a study of parallelism and hierarchy.

72 Parallel organisations are those in which authority (or a great part of it) is divided among many persons of equal rank. Hierarchical organisations are those in which authority is concentrated in one pair of hands, below which are others, having again others below them. In practice, neither exists in pure form; even the most parallel organisations have some measure of hierarchy and vice versa.

73 Broadly speaking, the more automatic a job, the greater must be the degree of hierarchy. A clerk adding up figures, a mechanic working a mass-production machine, or a typist copying shorthand must be supervised—not always, or indeed often, to check the actual performance, but to allocate the work to be done. Similarly, the more creative a job, the greater must be the degree of autonomy, which can only be obtained by parallelism. A hierarchy of artists need only be mentioned to demonstrate its absurdity. Yet an organisation of artists, whether for the holding of exhibitions or the production of a Walt Disney cartoon, is a practical proposition. An organisation of technicians may necessarily be hierarchical, for example the teams necessary to build a spitfire or remove a cerebral tumour. But most of the practice of medicine is still the application of individual judgment to the individual case. And, as long as this is so, parallelism as a dominant feature is desirable. But while parallelism among practitioners should be the rule, it does not follow that it is the final word in the medical administrative set up.

74 Some of the inherent advantages and disadvantages of the two forms of organisation will now be considered in turn:—

The *parallel organisation*—

(i) Opportunities of occupying senior positions, with a large measure of responsibility, are greatly increased. The chances of getting such a position at a relatively early age are also greatly increased. As a result, the presence of one able man in an organisation does not discourage others from entering it. Responsibility is achieved before age has sapped initiative and converted enthusiasm into disgruntlement with superiors. And a wide range of talent have the chance of liberal and varied expression. The merits of competition, such as they are, are also given free but not destructive play.

(ii) In organisations where members are required to display individual responsibility to others, it is particularly important that they should not be denied that responsibility themselves. To expect a person to bear the full weight of the troubles of others, while denying him the right to stand upright and foresquare himself, is as unwise in theory as it is unsatisfactory in practice.

(iii) By the parallel system of organisation, the dangers of bad appointments are minimised.

(iv) In all human communities, there are squabbles, bickering, and ill-feeling. Among equals these are less damaging to others, and less likely to lead to warping of character, than among superiors and inferiors. In hierarchies, the dissatisfied junior will appeal in the last resort to authority above his senior in the hope of displacing or replacing him. Thus, the apparent stability of a hierarchy is continually menaced, or, in minor key, administrative channels may be continually blocked by personal animosities. In a parallel organisation, the fact that two seniors are not on speaking terms is of relatively little consequence.

(v) The largest disadvantage of a parallel organisation is a certain difficulty in pure administration. Thus, it may be difficult to arrive at a policy decision, and once it has been arrived at, it may remain distasteful to some of the parallel seniors; their refusal to implement it is rendered easier by the absence of hierarchical control. This advantage may be reduced by placing administrative responsibility on one member of the parallel organisation, while keeping his status equal with his fellows. His directions must then be translated to his colleagues by tactful persuasion rather than forcible coercion. In a highly individual technical occupation, such as medicine, the refusal of senior members may, however, have inherent virtues. Time may prove the rebel right and the conformers wrong. This proof is likely to lead to correction quicker if accompanied by practical demonstration.

75 The *hierarchical organisation*—

(i) In a salaried organisation, it is usually cheaper to pay one man a very high salary, and proportionately lower salaries as one goes down the hierarchy, than to pay a number of men reasonably high but equal salaries.

(ii) If one is fortunate enough to have at the head of one's hierarchy an administrative genius, who also has wide human sympathies, he may produce a machine which works more happily and more smoothly than the best parallel organisation. But such men of genius are rare. If, therefore, an organisation needs only a single national head, a hierarchical appointment is justified. If, however, multiple local heads are required, parallelism has a better chance.

(iii) A mediocre hierarchical head—the usual situation—is in an unhappy position. He is responsible for all the activities of his subordinates, the great majority of which he cannot supervise. As a result he tends to sacrifice initiative to safety. His administrative superiors are usually themselves paper-workers. So he tends to sacrifice true efficiency to paper efficiency. "It doesn't matter if the patient dies, so long as he does it on the right forms."

(iv) His powerful position vis-à-vis his subordinates tends to produce in him dictatorial traits—a dislike of criticism, self-satisfaction, and parochialism.

(v) The senior workers in a hierarchy suffer from all the disadvantages which are avoided in a parallel system. Years of subservience turn their minds away from their work; they may preserve social equilibrium by concentrating on hobbies, sports, or pastimes, or they may become embittered misanthropes, or scheming intriguers, assiduously seeking out influential people and canvassing committee members.

76 The vivid contract between the parallel and the hierarchical systems is well seen in medicine. In the voluntary hospitals, and in general practice partnerships, the parallel system has been working with great success for many generations. The defects of these organisations are due to other factors. In the municipal and national medical services—e.g., the forces, the prison service, and the Ministry of Health—hierarchies have been the rule, and as a result second-rate rather than first-rate personnel has been the general rule. The parallel system makes the administrator equal with, and not superior to, the technical worker—whether clinician, laboratory worker, or teacher. The hierarchical system limits the opportunities of advancement of the clinician and confines the prizes to the administrator. Ultimately, it is on technical rather than administrative skill that the treatment of the patient depends; so technical skill should receive at least equal recompense with administrative ability.

77 It is possible that the initiative of the private business concern as contrasted with the government department may be due not to the inherent virtue of competition and private enterprise but rather to the existence of a controlling board of co-equal directors some of whom are usually technical experts.

Annual salary			Quarterly contribution			Persons	Total of contributions
£		£					£
300	—	350	7	8	0	250,000	7,400,000
350	—	400	8	15	0	152,000	5,320,000
400	—	500	10	0	0	70,000	2,800,000
500	—	750	12	10	0	760,000	26,000,000
750	—	1000	16	5	0	160,000	10,400,000
1000 and upwards			25	0	0	310,000	31,000,000
						19,010,200	316,581,805

Assuming that half those earning over £500 per annum elect to deduct ⅛ of their premiums, so as to arrange privately for medical treatment, £8,425,000 must be deducted—

less £8,425,000 = £308·7 million

X. Bridging the Gap

61. Figures so colossal as these mean little in isolation. They must be seen in the perspective of the total national income. The national income is defined as the money value of all the goods and services received by the people of the country each year. It is a money measure of the wealth of the country in terms of energy expended, apart from raw material possessed. In fact the acquisition of raw materials invariably involves the expenditure of energy—either in mining or growing them, or in manufacturing articles which may be handed over to those mining or growing them in exchange.

62. Before the war, our national income was roughly 4½ thousand million pounds. Since the war, it has increased by over 1¾ thousand million. This does not, however, represent an increase in real wealth, since nearly 60% of our goods and services are being used to defend the country rather than enrich it. Perhaps 3½ million people are devoting their time entirely to active war service, and at least that number to the production of munitions; against this, about 1½ million unemployed people are now at work, as well as a very large number of previously unoccupied women. In addition, all those who are working are probably working a little, but only a little, harder. Lease lend food and other material is also adding to our national income at no effort to ourselves. The cash value of this effort does give a measure of potential national income if it were all applied to peace-time purposes, though one must allow at least ¾ thousand million for rise of prices and inflation.

63. Our proposed health and social service scheme costs about 1000 million, or under ⅙ of our present nominal or potential real national income. Even if this were a withdrawal from the national income, a total loss as it were, we consider it is not an excessive price to pay for the abolition of poverty, and economic and medical insecurity. But it is *not*, in fact, a withdrawal from the national income but an orderly redistribution within it.

64. Our proposed social security contributions would yield about 300 million pounds. The remaining 700 million would have to be met by direct contribution from the Exchequer. It is worth noting that between 1926–38, 63·5% of all state income maintaining payments (under national health insurance, and unemployment, war and other pension schemes) was met out of taxation and not by the contributors.[11] We propose that the figure should instead be 70%. It is worth reiterating here the reasons why the whole sum should not come directly from the Exchequer; we consider that there should be a direct link in the minds of everyone between contributions paid and benefits received, and because the corporations should be free from detailed Treasury control.

65. The finding of this 700 million presents considerably less difficulty than the financing of the British national war effort; 11 million per day are being spent directly on war purposes; 700 million per annum is something under 2 million per day.

PART III

Running the Show

XI. Principles of Administration

66. The scientific study of administration is in its infancy. Scientific methods are more easily applied to material objects than to sociological ones. As a result, technical achievements have outstripped administrative organisation in local, national, and international spheres. In spite of this, technicians who have been forced to work in large organisations have remained inferior in status to the administrators. Science begins by observation and the classification of experience. Our proposals for health administration will be preceded by an analysis of past experience in both administrative and technical organisation. All new administrative proposals should be regarded as scientific experiments, and ours are no exception. Each phase of their operation should be watched carefully and modified or altered as proves necessary.

67. In past times, in Britain, laws were made by the nationally elected legislature, applied by the permanent executive, and interpreted when necessary by the independent judicature. This worked well as long as laws prescribed only conduct. In recent years, however, they have increasingly prescribed services to be performed by the state for the community. In the prescription of services, the legislature cannot do more than lay down principles which it wishes to be applied. In the application of these to individual cases, decisions have constantly to be made and rules of behaviour laid down. Such rules cannot be appealed against before the judicature unless they conflict with the principles defined by the legislature. Such rules are described as "legislation by the executive." Since this is a cumbersome phrase we propose to describe it as "direction."

68. No one who has had much experience of large administrative machines denies that direction is necessary inside a broad policy. The disputed question is rather who should give the direction. At present, it is given in four main ways:—

(i) By an executive Ministry of State, immediately responsible to Parliament, acting directly.
(ii) By the same, acting through locally elected authorities.
(iii) By a statutorily appointed public corporation.
(iv) By a coopted or created commercial company or private body—e.g., the insurance companies involved in the National Health Insurance Acts.

69. Each of these has worked well on occasion though each has disadvantages. The directly democratic nature of direction by ministries responsible to parliament, and by elected local authorities have made these methods popular in Britain. But as the technical and organisational complexities of the services to be supplied have increased, local units have been found to be increasingly inefficient. Further, day-to-day inquisition by Parliament into the minute direction of ministries of state has resulted in an over cautious playing for safety on their part, besides a cluttering up of parliamentary time. Finally, excessively democratic institutions tend to breed an excessive profusion of directing committees. For these reasons we favour for health administration a statutorily appointed public corporation, subject to periodical parliamentary review, with its governors appointed by directly elected ministers of the Crown.

70. In internal structure, any large organisation is subject to a series of mutually opposed forces, on the nice balance of which its efficiency depends. These are:—

(i) The technician *v.* the administrator.
(ii) Parallelism *v.* hierarchy.
(iii) The individual *v.* the committee.
(iv) The centre *v.* the periphery.
(v) Uniformity *v.* diversity.

final report may submit a minority report or may merely decline to sign the final document Examples of such committees are the various Royal and parliamentary commissions, and the Medical Research Council and its various subcommittees

86 Having considered committees, we come now to the individual in the organisation Here again, the position of the technician and the administrator differ slightly, thus the technician may stand alone, while the administrator has got to fit himself into an ordered pattern if administration is to go on at all But for both there are certain restrictions, conditions and safeguards which have to be seen clearly —

(i) Method of appointment
(ii) Method of remuneration
(iii) Conditions of tenure
(iv) Principles of advancement
(v) Possibilities of change

87 We think that *all* appointments above the most junior level should be advertised publicly, however strong an internal candidate may be Appointments should be made by boards rather than individuals Examinational entrance has little to commend it, though exam results may be an important factor for an appointing board

88 A strictly logical scale of remuneration is impossible to devise In a community where there are attractive jobs for all it may be necessary to raise the salaries of less attractive jobs above the general level But in the long interim period before such a Utopia exists, we suggest a steady drawing together of maximum and minimum salaries with parallelism on each level Thus where there are a number of heads of departments they should be equal in salary and status If there is one executive head of a group of directors (e g , a director-general) he should be *primus inter pares* , his salary should not differ from his colleagues and the reward for his additional responsibility should be his additional authority The ranges on both administrative and technical sides should be the same

89 Security of tenure is a difficult question There is no known post which is completely secure though there are many from which dismissal only follows discovered dishonesty and not laziness or inefficiency It is argued that security both attracts and produces people lacking in enterprise and initiative Equally, its absence makes for intrigues designed to displace unpopular seniors There are two other peculiar by-products of security , one bad senior appointment may stultify a whole organisation for years , to cure this the strange practice of dismissal by promotion may occur a man is got rid of from one section by recommending him strongly for a higher appointment in another In medicine security of tenure has been the rule rather than the exception The medical officer of health is statutorily secure to enable him to stand up to the wayward local authority In parallel organisations such as the voluntary hospitals, security does not as a rule lead to a decline in initiative, at the same time, appointments are made with the greatest care, and initiative and character are usually regarded as important factors On the whole we favour security for the technician and security with limited tenure for the administrator At the end of an administrator s tenure, transfer rather than reappointment should be the rule and retirement or dismissal should not be so rare that it carries with it disgrace

90 Principles of advancement follow automatically from the method of appointment If all but the most junior posts are advertised and if appointments are made by boards, promotion by seniority should be confined to those cases where seniority is combined with merit

91 Possibilities of change are limited for everyone A man may give hostages to fortune in the shape of a house or a family which tie him just as much as a formal contract There is however one form of tie which can easily be remedied—the fixed superannuation scheme Inside an organisation, all superannuation schemes should be mobile and anyone leaving an organisation should be able either to take his scheme with him or to receive an adequate lump sum benefit Broadly speaking, we think that internal staff movements among both technical and administrative staff should be encouraged Administrative staff should move both in the geographical and in the organisational planes In five years a good man will have mastered any administrative or executive job If he has not done so in that time he never will We therefore recommend fairly regular transfers from one job to another and from one part of the country to another Such transfers should not be inevitable but should be encouraged

92 To speak dogmatically about the optimum age of administrators is difficult as one man may be old at 40 and another young at 60 But, as a general rule, posts calling for initiative and enterprise no matter how senior, should be held by younger men , those requiring wisdom and critical faculties, such for example as personnel selection and arbitration by older men It is particularly important that the tenure of office of the young senior should be limited

93 An administrative problem of great importance is dual control This situation arises when two authorities jointly administer one machine It is successful only when the interests of the two authorities are entirely mutual (e g , where two small counties combine to own a joint mental hospital) But this is seldom so As a general organisational rule dual control is a compromise to be avoided On occasion a pseudo-dual control giving the feeling of satisfaction to one authority, and the actual power to another may work extremely well

94 Every large organisation has a nerve centre and a number of peripheral units The size and number of such units should be determined by their function To allow units of historical interest only to override functional need is certain to lead to inefficiency In each peripheral unit, the principle of parallelism should be applied Its administrative head should be equal in salary and status with the headquarters officer exercising general control Peripheral officers in charge of large sections under the peripheral administrative head should have similar salaries and status Interchange of staff between headquarters and the periphery and between parts of the periphery should be continuous and should carry with it no stigma Thus freshness is ensured, and the evils of bad appointments are minimised Visiting between the periphery and headquarters should be encouraged Peripheral devolution of authority, particularly a large degree of financial authority is essential if work is to be done smoothly and quickly and there should be room for peripheral experimentation Thus the pattern of each peripheral unit should not automatically be uniform Much may be learned from a study of the regional organisation of war-time ministries, both as to precepts to follow and mistakes to avoid

95 Every large organisation is continuously in touch with the public Its smooth working depends in part on the greasing of these points of contact Greasers are known as public relations officers A public relations officer must make sure that members of the public know the services which are being offered to them that their just criticisms are met, that their unjust ones are explained, and that courtesy and consideration are continuously in the minds of all within the organisation who make contact with the public A joint training in sociology and advertising is a good background for a public relations officer, but ultimately personality is the most important factor in public relations work

78. We have, then, no hesitation in recommending that in a national medical service, parallelism should be the dominant feature of the technical side, whether this be general practice, hospital practice, laboratory work, teaching, or research. In environmental medicine and in pure administration, a greater degree of hierarchy is probably inevitable, but even here it should be kept to a minimum.

79. Turning now to the question of the rôle of the individual and the committee, it is well to consider first the limitations of committees, and then their varieties and functions. It has often been noticed that the decisions of committees are far worse than those of the individuals who compose them. This is not really surprising, for the evidence before a committee is seldom clearly and logically set out, the members have little time for reflection and consideration, and what they say is often a superficial judgment or a comment on an individual point only. Good committee members are rare; it should follow that committees called upon to make decisions should be equally rare. On the other hand, committees make excellent sounding boards for new proposals.

The following types of committee commonly occur:—

(i) Legislative
(ii) Directing
(iii) Executive or administrating
(iv) Coordinating
(v) Advisory
(vi) Judicial
(vii) Research or investigating

In practice, committees often perform more than one of these functions.

80. *Legislative and directing committees* may be considered together, since by our definition, a directing committee is one legislating within a field defined by the national legislative body. We support the view that legislative and directing committees should ultimately be responsible to those for whom they legislate. But, except in the case of the national legislature, we oppose a day-to-day inquisition, both because this stultifies enterprise, wisdom and long-sighted planning, and because many decisions must be based on highly technical evidence. In Britain, a 5-yearly mandate for such committees has been found to be a good working rule. At the end of that time, it is wise to call them to account. In addition, they may issue annual reports of their activities, which, along with their other activities, are constantly commented on by public opinion. Since directing committees are mainly concerned with technicalities, their members are best appointed not by public election, but by private selection—by, say, a minister of state and the privy council. To avoid restriction of the field, vacancies on such directing committees or boards should be publicly advertised. It is essential that some members (and perhaps the chairman) of such a committee should be non-technicians, eminent laymen who are capable of safeguarding public interest against technical interest. To prevent staleness, a limit on reappointment must be placed, and to ensure continuity, retirement must be by rota. The powers of a directing committee must be defined by the national legislature.

81. *An executive or administrative committee* carries out the policy decisions as instructed. In practice, such a committee can only consist of individuals personally responsible for the branches of an administrative machine; if the members are not themselves administrators, they will often be unable to ensure that the administration is in fact carried out. An administrative committee cannot be the head of an administrative machine. This head must be a single individual, hereinafter called the director-general. He must be appointed by, and be capable of being dismissed by, the directing committee or governing board. For him to be fully informed, he must attend the board's meetings as its secretary. In implementing the board's policy, he will need to discuss with and instruct his own senior officials. It is for him to decide whether this is best done individually, or in committee. Such a committee is not one at which votes are taken, since, if he wishes, the director-general can over-rule all its members. The task of schooling administrative committees is one calling for great patience, tact, and firmness.

82. *A coordinating committee* may not differ greatly from an executive or administrative committee. It is a gathering of equals who are aiming to fit together their varying tasks. However, unlike an executive committee, coercion of the members is impossible, and success depends on the tact and perseverance of the chairman. Coordinating committees have special interest in medical organisation because existing regional hospital committees are of this type. Coordination only presents big difficulties when the common good demands that some of the coordinators shall surrender a part or the whole of their work. In a perfect world, a coordinating committee would be enough; but since even hospital administrators are human, some overriding power must strengthen the work of a coordinating committee. The best overriding power is the control of the purse strings.

83. *Advisory committees*, properly used, are of enormous value. They should not be elected, but coöpted with great care. Some members may be chosen as public figure-heads, but the majority should be there because their advice is really valued. The wise administrator, when faced with an awkward decision, will take the opinion of his advisory committee. Not only will its advice be inherently valuable, but it will provide a private and public bulwark if the decision is questioned. The BBC has used advisory committees with particular wisdom. A special variety of the advisory committee is what may be called the public relations committee. This may be chosen on a geographical or a functional basis. Its task is to reflect the feelings of the public it is chosen to represent, to pass back to its public the decisions of its parent body, and to obtain explanations of public misapprehensions or misunderstandings. Local examples of such committees are being increasingly used by national organisations, and are proving of great value. It must be emphasised that such committees need careful training if they are to be prevented from trying to take on directive or executive functions, and this training takes time and patience.

84. *Judicial committees* apply general rules to particular cases to settle disputes. Where no general rules are accepted by the disputants, judgment had to be based on practical consideration of all the facts presented; on such occasions, a utilitarian yardstick is invaluable. In the application of well-defined rules, legal training and experience is desirable in most members of the committee. In general arbitration, a legal chairman is a great help, but the committee should include members who may be regarded as equals of the disputants—e.g., in a dispute between a trades union and a group of employers, the arbitration committee should include representatives of both unions and employers.

85. *Research or investigating committees* have two methods of study open to them. They may invite or order the submission of evidence, written or spoken, and may cross-examine witnesses, and they may arrange for the carrying out of research; this may be done by individual members of the committee or by commissioned investigators. In practice, the success or failure of a research committee depends almost entirely on the intelligence and personality of its chairman and secretary. For any big undertaking, the secretary should be whole-time. To the chairman and secretary will usually fall most of the drafting of the committee's report. The draft report will then be circulated to all members for criticism and correction. Members disagreeing with the

counties). The senior regional officer should be the regional director, though in Scotland and Wales he might well be a controller. As a general rule, he should be a medical practitioner. The regional office would be the main channel through which the national health funds flowed to hospitals, health centres, and practitioners. Each regional director should be assisted by a general regional advisory committee, and a number of regional technical committees, one of which should be the regional medical advisory committee. The general regional advisory committee should include representatives of the local authorities, the local university or universities, the medical and nursing professions, and possibly local trades-unions and industries. Similar organisation on a subregional or county level is also desirable.

106. The main regional coördinating committee should be the Regional Hospital Committee, composed of representatives of all hospital owning bodies or authorities. The chairman of this committee should be the regional director. It would be the duty of the National Health Corporation to ascertain the medical needs of the population throughout each region, to make sure that these needs are met, and that the conditions of all those working in the health services fulfil the authorised standards. In carrying out this work, it will be necessary to give directions to hospitals on the subjects of size, function and staffing. The regional hospital committee will be the place at which the problems of coördination are thrashed out. Financial control will be the first force by which the corporation's directions are made operative. The corporation should also have the power to acquire compulsorily recalcitrant and inefficient hospitals. The corporation should not be squeamish in exercising these powers if necessary; efficiency should be regarded as more important than autonomy.

107. If elected Regional Councils, analogous to county and county borough councils, are established by law, they should be closely linked with, but should not control, the regional organisation of the National Health Corporation. The regional director might be their health advisory officer. They should nominate representatives on the regional advisory council, and they might be hospital-owning authorities.

108. While it is in theory desirable that all hospitals and other health buildings should ultimately be the property of the National Health Corporation, we recognise the need for a compromise. Provided that the staff of the hospitals were members of the corporation, the actual ownership of the fabric need not change. The present owning bodies could continue to appoint the hospital committees or governing boards, though the functions of these committees would approximate much more closely to those of a voluntary hospital board of governors than to a municipal hospital committee. Medical staff committees in hospitals would be the rule.

109. To strengthen the links between the local public in each small area and their health services, we propose that local health committees should be set up. These should be responsible for reflecting local sentiment about all health problems to the corporation, and for organising the supply of local health information to the community. Representatives of local practitioners should attend these committees to keep them informed of local progress and difficulties. Some members should represent the different parties on the local authority; others should be coöpted to represent other local interests, especially the local workers; a definite proportion of the members should be women.

110. Both the National Health Corporation and the Social Security Board should be linked to the Ministry of Health in much the same way that the BBC was formerly linked to the Post Office. Since the income of both would be derived first from the Social Security contributions received by the board, and secondly from a Treasury block grant, the Ministry of Health might nominally hold the pool into which both these were paid, and from which block grants were made to the corporation and the board. The expenditure of both would not, however, be under the supervision of the Ministry and the Treasury, but under their respective boards of governors. The Minister would answer in the House for the broadest lines of policy only, and not for any details of day-to day or year to year business.

PART IV

The Doctor and His Work

XIII. An Outline of the Medical Services

111. Broadly speaking, doctors who serve the community, fall into three groups:—

(i) The home doctor—family doctor, or general practitioner.
(ii) The specialist or consultant.
(iii) The social doctor—environmental doctor, or medical officer of health.

The first two are concerned with the individual patient, and are primarily clinicians. The third is—or should be—concerned with patients en masse. Doctors perform other important functions, in particular:—

(i) Teaching: technical for medical students, student nurses, and other technicians; and (to a small extent) popular, for members of the public.
(ii) Research.
(iii) Administration.

But each of these functions is carried out by doctors who continue to be, or have been, members of the three primary groups.

112. There are a few people who believe that the day of the general practitioner, hereinafter called the Home Doctor, is over, and that patients should be dealt with from the outset by specialists. This proposal is only logical if it envisages a new type of specialist—the preliminary diagnostician or sorter. It envisages also a battery of specialists geographically situated so that they can see every sick persons. From this, it follows that routine domiciliary medical attention must end, and with it the intimate knowledge of the home circumstances of every patient which is a priceless asset of the good home doctor. While we admit that there is room for improvement in the diagnostic training and skill of the home doctor, we consider that these proposals are grossly wasteful and are not in the best interests of the public. We think that the personal relationship between the home doctor and the patient is as real and important as it is hackneyed. We therefore accept the principle of the three types of doctor enumerated above, though we are by no means satisfied that the services they offer to the public are all that they should be. In particular, we would point out that special training or experience is provided for specialists and medical officers of health (hereinafter called social doctors) while none is provided for or demanded of the home doctor.

XIV. The Home Doctor

THE PATIENT'S POINT OF VIEW

113. From the patient's point of view, the home doctor has the following functions to perform:—

(i) He must be the doctor of the patient's choice.
(ii) He must examine and advise the patient at a point reasonably near the patient's home at a mutually convenient time, whenever the patient wishes it. The conditions of examination must be such that the patient is satisfied that all that can be done, has been done. Time for examination and explanation must be adequate.

XII Administration of a National Health Service

96 If the public throughout the country is to receive the best possible medical attention and treatment, regardless of individual or local poverty, a nationally organised health service is essential. The health service we have in mind is that concerned with the personal needs of the individual; environment services, which are primarily the concern of non-medical technicians, should be under separate control. Bearing in mind the general principles of administration already considered, we make the following proposals.

97 We are firmly of the opinion that the central authority of the national health service should be a corporate body and not a department of state directly under a minister of the Crown. Our reasons for this view are:—

(i) In departments of state, hierarchical organisation is the rule. In corporate bodies, a high degree of parallelism is possible.

(ii) Policy in medical matters must be long-term. To submit it to day-to-day or even year-to-year inquisitions in Parliament is to discourage bold planning and initiative and to invite playing for safety.

(iii) The principle that the best possible health services should be made available to all is no longer a political issue.

(iv) The maintenance of health is a joint task for the technician and the layman. To place the technician under the layman (as in a Government department) or the layman under the technician (as in martial law) is not to get the best out of either. They must in fact work together and equally.

98 The powers of the corporate body, hereinafter called the National Health Corporation, should be vested in a board of governors, in numbers not more than 7—a lay chairman, 3 medical members and 3 lay—at least one of whom to be a woman. We consider that any greater medical loading of the board might lead to accusations of self-interest in medical administration. The initial members should serve for from 3 to 7 years and thereafter members should serve for 5 years. Reappointment should never occur more than once. The board should be appointed by the Privy Council, on the advice of the Prime Minister and the Minister of Health. Members of the board should receive salaries, but it should not be their exclusive occupation. Vacancies on the board should be publicly advertised (as should every post in the corporation), but the choice should not be limited to the applicants. The work of the corporation should be subject to 5-yearly scrutiny, and its charter to 10-yearly renewal by Parliament.

99 The corporation should be charged with the spending of the national health funds, apart from purely monetary relief of the sick and their dependants. The funds would take the form of a block grant from the Social Security Fund, itself derived from the social security insurance payments and an exchequer contribution (see ¶ 43–46). The corporation should be empowered to acquire, own, and build hospitals of all types, clinics, health centres, offices, and other property. It should automatically acquire hospitals owned by the Ministry of Pensions and the EMS buildings, but not voluntary or municipal hospitals.

100 The principal executive officer of the board should be the Director General. Except in very exceptional circumstances, he should be a medical practitioner, and he should be *ex officio* secretary of the board. He should have a deputy. The senior officers in charge of large sections of the corporation's work should be Controllers. The salary ranges of the director-general and the controllers should be the same. Below each controller should be the directors of divisions, including peripheral directors in charge of geographical rather than functional divisions. These directors and their deputies should be on the same salary ranges.

101 Advisory committees should play a prominent part. All should meet regularly. Their members should mainly be coöpted by the board, and should sit for 5 years, being eligible for reappointment for another 5 years. They should receive honoraria. Senior officials of the corporation should attend the meetings. There should be a general advisory council, composed of men and women eminent in public life, medicine, nursing, the ancillary health services, the sciences, and even the arts. Technical advisory committees should cover the various aspects of the work of the corporation, and on these some members might well be appointed by the Royal Colleges, the British Medical Association, the General Medical Council, the Universities, the various nursing bodies, Government departments, the trades unions and organised industry. The corporation should make no attempt to take over the work of the British Medical Association or the General Medical Council.

102 The position of Scotland and Wales demand special consideration. If the burden of social security is to be uniformly distributed, they must be included in the national collection and distribution of money on the same basis as the rest of Britain. It would, however, be possible to organise separate health services for both. The advantages of this would be the satisfaction of national pride, and the possibility of a freer experimentation. The disadvantages would, in our opinion, outweigh these advantages. Interchange of personnel should play a large part in a national health service. If the Tweed and the Marches are to be barriers in this interchange, all sides will be losers. We therefore favour a national health corporation which cover Scotland and Wales. Both should however be treated as special units, with their own controllers and geographical advisory committees having the status of councils.

103 We are satisfied that the units of local administration in Britain are at present too small for efficiency. The new areas, hereinafter known as regions, should coincide as far as possible with the national regions adopted for civil administration. A multiplicity of functional regions, as at present, makes for inefficiency whenever functions overlap. Such regions may not always be ideal for health purposes, but the losses as a result of faulty geography are likely to be less than those resulting from a multiplicity of borders. Assuming that the present civil defence regions are adopted the following general modifications appear necessary:—

Region 1 (Northern), Region 3 (North Midland), Region 4 (Eastern), Region 6 (Southern), Region 8 (Wales), and Region 10 (North Western) each need dividing into 2 subregions. North Wales may need to be linked functionally with Cheshire and South Lancashire. Region 5 (London) could conveniently be enlarged. Region 7 (South Western) needs dividing into 3 subregions. Region 11 (Scotland) is already divided into 4 subregions and may require further subdivision.

104 If the regions are to be entities in the life of the people, it will be necessary to get rid of the present cumbersome geographical nomenclature. As a tentative suggestion, we offer the following names:—

Region	1	Tyneland	Region	7	Westland
,,	2	The Ridings	,,	8	Wales
,,	3	The Shires	,,	9	The Midlands
,,	4	Anglia or Fenland	,,	10	Lancastria
,,	5	London	,,	11	Scotland
,,	6	Wessex	,,	12	The Weald or Eastland

At this point, it should be clearly stated that the regions proposed are administrative and not medical; a patient choosing a doctor, or even a hospital, "over the border" should be free to do so.

105 In each region, the corporation should have an administrative office, with smaller offices in the subregions, or alternatively in each county area (county boroughs to be treated for this purpose as parts of

(v) By arrangement with his colleagues, he must have regular and adequate off-duty times. He must have regular holidays.

(vi) Once every 5 years at least he must have a refresher course specially planned for his needs.

(vii) Within his general field he must have opportunities for acquiring and utilising special skills.

(viii) He must keep in contact with his colleagues, general and specialist, and for this there must be a physical focus. His primary focus will, in fact, be the health centre; his specialist focus will be his local polyclinic and hospital.

(ix) He must be adequately insured against sickness and provided for in old age.

A consideration of these points will make clear our proposals for the home doctor service.

123. We propose that all practices which are about to fall vacant, or have fallen vacant by sudden death, should be compulsorily advertised in the medical journals. Such advertisements should have a set form giving the essential data. The appointment should be made by a small board, on which should sit representatives of the regional office of the National Health Service and of the regional medical advisory committee; one member of the staff of the medical committee of the health centre concerned, preferably the retiring or vacating doctor, should also sit on the board. The patients on the list of the retiring or deceased doctor should be invited to choose a new doctor from among all those working at the centre, including the newly appointed practitioner; they would be asked to make a definite choice, and would, of course, be free to change their choice later if they wished.

124. In newly developing areas, where more home doctors or health centres are needed, a board similar to that for a death vacancy should make the appointment from among the candidates applying. Such need will be indicated to the regional office of the National Health Corporation by its medical intelligence service, the peripheral officers of which will be the medical officers of health. The determination of need involves a detailed knowledge of each locality, and a periodical local census. This could be made from the social security registrations.

125. Each doctor at a health centre would accept patients for his list up to a prescribed maximum number. He would be free to refuse to accept patients, but having accepted them, he would be under an obligation to treat them in their homes and at the health centre, and to arrange for consultations and hospital treatment for them whenever necessary. His remuneration would consist of three parts:—

(i) A basic salary with additions for special qualifications and length of service.

(ii) A capitation fee depending on the number of persons on his list.

(iii) Fee for special clinics or other special work, and private fees for patients choosing to be outside the service.

The terms and conditions of service should be on a national basis, and should not be altered without consultation with the organised medical profession. The salary, capitation, and special fees should be paid from the corporation funds. Deductions should be made for pensions, dependants' pensions and sickness and disablement allowances. In the event of a practitioner leaving the service, his contributions should automatically revert to him. Contributions and benefits should be unaffected by change of occupation within the service.

126. Practitioners entering the service from existing private practice should be offered guaranteed non-contributory retirement and death pensions in compensation for loss of capital. The sale of practices within the service would not be permitted.

127. We come now to the actual organisation of the health centre. To limit the amount of travel of patients, centres should not be too large (6–12 doctors). The centre should be purchased or built, and owned and maintained by the National Health Corporation. The building should be pleasing and utilitarian within and without. Each doctor should have his own consulting-room and there should be an additional consulting-room for visiting specialists. We regard it as important that doctors should not share rooms on a Box and Cox arrangement, as each room should develop its occupant's personality. There should be several common waiting-rooms not used for any individual doctor. All patients, on arrival, and on departure, should pass through a receptionist's office, for record purposes, the issue of patient's notes by the receptionist to the doctor (not the patient), and the booking or collection of private fees. There should be a small theatre for minor surgery, a small surgery for septic work, a pathological room for simple diagnostic investigations, a small X-ray room and possibly a room for physiotherapy. There should be a dispensary in charge of a pharmacist who should also act as supply officer for instruments, stationery, and equipment. Dispensing on the spot would save an enormous amount of the public's time and the dispenser would be in a position to check excessive prescribing at source. In addition, there should be rooms for the local district nurses, midwives, and health visitors. There should be a resident caretaker who would also act as telephonist. At least 2 secretaries would probably be needed for a centre with 8 or more doctors; they would undertake clerical work and record keeping.

128. In no circumstances should any inpatient work be undertaken at the centre.

129. Within the centre, the whole medical staff sitting as a committee would arrange the hours of work, emergency rotas and night calls, holidays, and other internal matters.

130. It would be the duty of the centre to provide antenatal, natal, postnatal, and infant and child welfare services. It would also provide staff for school medical inspections. If one or more practitioners specialised in midwifery and infant and child welfare, taking over cases from their colleagues, they should receive extra remuneration but the length of their permitted list should be reduced.

131. The centre, especially the pathological and X-ray sections, should be closely linked with one local hospital, and the work done in these two sections should be supervised by the appropriate hospital specialists. Doctors at the centre should be attached officially to the local hospital.

132. At the centre there should be one or two whole-time salaried assistants, junior practitioners gaining experience in home practice. They should be assistants to the centre and not to individual doctors and the committee of the centre should decide their work. They should help and deputise for the seniors, who in turn should instruct them as much as possible. Assistantship would be a sine qua non for a doctor applying for a senior post at any health centre. Normally an assistant would hold the post for from 6 to 12 months.

133. The centre should encourage an emphasis on health rather than sickness in the community it serves. It would have an important part to play in health education, by lecture and by individual instruction. Individual centres should experiment with periodic health examinations to ascertain their value and dangers, if any. Prophylactic services, such as vaccination and immunisation, should be undertaken at the centres as a regular part of the service.

134. There is much to be said for incorporating two or more dentists in each health centre.

135. In rural areas, the doctor's surgery should become a one-man centre. Adjacent country practitioners

When the patient is more severely ill, the home doctor must visit the patient's home

(iii) He must give the same standards of advice and skill to all his patients, regardless of their class, social status, or income The standards must be the highest he can achieve

(iv) When he has reached the limit of his skill, he must not conceal the fact from himself or the patient He must then arrange for the patient to see an appropriately skilled specialist, and must cooperate with this specialist in carrying out treatment when the patient leaves the specialist's hands Furthermore he must arrange for a specialist opinion at the patient's request, even when he himself considers this unnecessary

(v) When it is necessary, he must arrange for the patient to receive appropriate institutional treatment

114 Each of these functions requires further examination The value of freedom of choice of doctor, even though it is in part illusory, has already been discussed (¶ 36) That the "point of examination" must be reasonably near the patient's home is self-evident In urban areas, such points may conveniently be Health Centres, at which a number of practitioners work, in rural areas, such grouping is impossible, and the practitioner's surgery and consulting room must act as the health centre The advantages to the patient at such a centre are that the necessary devices for special examination will be at the doctor's hand, that dispensing if done will probably be more rapid, and that the presence of several doctors at one spot is likely to raise the standards of work of each

115. That all patients shall receive only the best is another self evident proposition Perhaps, naturally, many panel patients believe that home doctors favour their private patients Though the belief is more widespread than the facts justify, it has some basis Doctors are subject to the same weaknesses as other men, and social barriers are not unknown in medical homes, the poor waiting on benches and the rich in the dining-room is not yet a thing of the past We consider that the health centre will go a long way to removing these ideas Private patients may elect to see their doctor in his own home or at the health centre As they come to appreciate the value of the services which the centre offers, they will more and more tend to use it Waiting-rooms at the centre should be arranged according to the doctors to be visited, and not on a social basis The standard of waiting-room furniture should be as high as possible and the same for all There should be an appointment system available for all Private patients attending without appointment should not receive preferential treatment over insured patients attending thus

116 A third self-evident proposition is that the skill of the home doctor is limited At present, many home doctors do work which in large towns is entirely in the hands of specialists While we recognise that some home doctors are competent surgeons, radiologists and pathologists, we consider that even the best of them are less valuable to their patients than reasonably good specialists This is no reflection on their efforts, since in these specialties constant practice is essential if the best results possible are to be obtained, and home doctors are inevitably denied such constant practice The proper place for the home doctor surgeon, if he is competent, is in the ranks of the specialist We have cited the best The average is far below this, and at worst, the home doctor operating in a small hospital staffed only by other home doctors may be a serious menace to the neighbourhood This menace is the greater because the public have no standards by which to judge his surgical skill

117 We realise that any proposals to limit the surgical and specialist activities of the home doctor will meet with some opposition Since, however, our primary concern is the welfare of the public, we must state categorically that for specialist work, specialists must be used Lest we are thought to be discriminating against the home doctor, we would add that the remuneration of the home doctor should not differ materially from that of the specialist

118 In his own field, the home doctor must in fact be a specialist An outline of that field should convince all reasonable people that he has enough on his plate without recourse to other specialties He must be an expert in —

(i) General bedside diagnosis, especially medical and surgical emergencies

(ii) General home treatment (including, in remote areas, dispensing, but excluding biochemical medicine such as the stabilisation of diabetes, and specialised treatment such as venereal disease)

(iii) Simple clinical pathology

(iv) The diagnosis and home treatment of specific fevers, skin diseases, diseases of the eyes, ears, nose and throat, children's diseases, gynæcological diseases, and minor psychiatric illnesses

(v) After-treatment of all institutionally treated illness

(vi) Child welfare

(vii) Ante- and post-natal care, and possibly midwifery

(viii) Minor surgery and medical first-aid in surgical emergency (excluding anything but the first-aid treatment of fractures)

(ix) Forensic medicine as it affects general practice

119 In addition, he has to be a guide, philosopher, and friend to his patients and their families, and a combination of home health educator (ready with advice on ventilation, diet, exercise, rest and sleep) and health public relations officer and almoner (making sure that those who need and are entitled to help know where and how to get it)

120 This formidable list brings home again the point *that the training of the home doctor* should be very different from what it is At present, he wastes many hours in the dissecting-room and the operating theatre which should be spent in the fever hospital, the children's ward, the special outpatient department, the social welfare department, and above all, in the health centre itself

121 But if we consider that the home doctor must be a specialist in home doctoring and not an operative surgeon, it does not follow that he should play no part in institutional treatment Whenever physically possible he should have facilities, not only for following his patients through the hospital, but for playing an active part in hospital work The details of our proposals will be considered later (¶ 128)

THE DOCTOR'S POINT OF VIEW

122 The doctor's point of view is, in fact, complementary to the patient's Unless the home doctor is working under the best conditions, he will not be able to give his patients the best service The conditions we consider essential are as follows —

(i) He must not have to "buy his way in" to a practice His early years in practice must not be crippled by the heavy debt which purchase so often involves

(ii) He must be a free man—free to throw up his practice if he wishes so to do, free to refuse to accept a patient (though having once accepted, he must carry *out his obligations), free to increase* his practice by his own efforts up to a point where it is generally judged that efficiency is reduced, and free from undue bureaucratic interference, whether medical or lay If he fails to carry out his statutory obligations, he must be subject to statutory discipline, and not the inroads of officialdom Unless our doctors are free men, they will lack the sense of responsibility on which the doctor-patient relationship rests

(iii) His remuneration must be adequate, from the outset of his career, and must bear a relation to the amount of work he does

(iv) He must be adequately housed, and adequately equipped for his work via a regional hospital committee. These functions would be:—

(i) The provision of a complete outpatient department or polyclinic for:—

(a) Specialist advice for patients sent by home doctors from health centres.

(b) Outpatient treatment of special diseases and conditions beyond the scope of the home doctor and the health centre—e.g., tuberculosis, venereal disease, fractures, diabetes.

The polyclinic would in fact resemble the outpatient department of a large voluntary hospital, plus a tuberculosis dispensary, and a venereal clinic, but without a casualty department or a department for treating the minor sick as outpatients. It would be staffed on a sessional basis by specialists coming out from the key hospital; these specialists would also supply a domiciliary and health centre consultant service in case of real need. Special small consulting-rooms would exist for patients wishing to see specialists individually. Such private treatment would be supplied either to those who paid an additional insurance charge or to private uninsured patients; in the former case, they would be seen by whole-time salaried consultants; in the latter, by the part-time staff as fee-paying patients; all such fees should, however, be collected by the almoner.

Posts as assistants in the outpatient clinic should be available to home doctors working at health centres. All doctors from attached health centres should have the right to attend at all non-private outpatient sessions.

(ii) The provision of beds (private and public, arranged on the same basis as for outpatients) for:—

(a) Acute medical and surgical emergencies for adults and children. These beds should be in the immediate charge of an RMO and an RSO; these posts should be occupied only by doctors having higher qualifications and should be equivalent to or immediately above registrar status. The RMO and RSO should work under a rota of key hospital consultants, always on call. Emergency surgery should be done by the RSO or a key hospital consultant; anæsthetics should be given by the RMO, another resident, a resident anæsthetist or the home doctor.

(b) Minor illnesses for which home nursing cannot be arranged. Such cases should be seen on admission by the RMO or RSO. If he is satisfied, they should remain under the charge of the admitting home doctor. If the need arose the RMO or RSO should have the power to call in a key hospital consultant, though not without informing the home doctor except in case of emergency.

(c) Midwifery.—Depending on the size of the department the admission and general supervision should be undertaken by the RSO or a resident accoucheur. Home doctors should, if they wish, handle their own cases, but a key hospital consultant should always be on call.

(d) Acute infectious fevers, including smallpox. We are satisfied that there is no medical need or justification for separating fever hospitals from other hospitals. We consider that geographical isolation has had a bad effect on both fever and nursing personnel, and that the patients have been the ultimate sufferers. Fever beds should be in the immediate care of the RMO or a resident fever officer, who should work under a key hospital fever consultant.

(e) The chronic sick, the infirm and the slowly dying. We consider it essential that these patients should be nursed reasonably near their homes, and that they should *not* be cared for in isolated institutions to which they feel they are sent to die, and in which they often sit and rot. They should be looked after on the same basis as the minor sick.

(iii) The provision of a pathological laboratory and radiological department. The former should be in the immediate charge of the RMO or a resident pathologist, working under a key hospital pathologist. The latter should be under a visiting key hospital radiologist, with RSO or a technician trained for emergencies.

(iv) The provision of the department of the medical officer of health, hereinafter called the social physician. He should be responsible for all health and sickness records in the hospital, the attached health centres, and the area served, as well as a number of other duties which will be discussed later.

(v) The provision of a hostel, attached but not necessarily immediately adjacent, for the children under 15 of local women admitted as patients to the medical centre or the key hospital. We consider this a vital health service, inasmuch as the care of children exercises a powerful inhibiting factor on women who need but refuse hospital treatment. We think that children over 14, and husbands, should be quite capable of fending for themselves. Children of sick mothers being nursed at home should also be eligible for admission. As far as possible, they should continue to attend their own schools during the day, but if necessary should attend local schools nearer at hand.

143. The medical centre would thus become an outpatient diagnostic and treatment centre, and an emergency treatment centre (including under this heading fevers and midwifery), a hospital for the minor sick, and a home for the chronic sick. The home doctor would enter far more into its work than he does as a rule at present, but no patient would be isolated from the best available skill.

144. The medical administration should be in the hands of the RMO and the RSO who should be appointed on the advice of the key hospital medical committee, to whom the work of appropriate junior staff would be well known. The lay administration should be in the hands of a lay administrator, a secretary, steward, or administrative officer, paid like the rest of the staff, by the National Health Corporation. The lay hospital committee, whether voluntary or local authority, should meet monthly, or better, quarterly to receive the reports of the secretary, RMO and RSO, and to deal with such matters as was necessary. A medical committee, composed of the visiting key hospital specialists, plus some home doctors representing local health centres, and the local medical officer of health should advise both the lay committee and the regional authority.

145. *Key hospitals* would be existing large voluntary or municipal hospitals, or new hospitals. At least one in each region should be directly linked with a university as a main teaching centre, and some undergraduate or postgraduate clinical teaching should be carried out in all key hospitals. There would be no inherent objection to having two or more key hospitals in any large centre of population, provided the rest of the region were adequately served.

146. At each key hospital there should be a complete functional replica of the medical centre, first to provide the necessary services for the population and health centres in the immediate neighbourhood and secondly to provide the teaching facilities needed in outpatient and minor medicine, fevers, midwifery, and the care of the chronic sick. The student should, however, gain his necessary casualty experience as a dresser attached to an adjacent health centre.

147. Inpatients would be received exclusively from medical centres (including the key hospital's own section) on the advice of the key hospital's own staff who had seen them as outpatients. Patients desiring privacy, whether paying extra insurance or private fees, should, as far as accommodation permits, be treated privately. The only privilege privacy would carry with it should be freedom from being taught on and demonstrated. In all other respects,—nursing, theatre, medical attention, food, &c.—conditions should be identical.

148. The type of case entering as an inpatient would include all cold surgery, semi-acute, and chronic medical cases of all types requiring investigation and treatment, and all types of case admitted as a result of local hospital functions.

149. In internal organisation, the key hospital should resemble closely the voluntary hospital. A series of parallel and equal medical, surgical, and other firms or units would operate. Typically, each might consist of a should be affiliated to the larger centres in their local country towns, so that they have the benefit of assistance and the services offered by the centre In rural areas normally covered by country town practitioners, outlying surgeries might form a part of the centre All doctors doing rural practice should have cars convertible into one bed ambulances (by lowering the back of the seat next the driver)

136 Certain types of case should invariably be referred from the centre to the specialised clinic attached to the local hospital These include tuberculosis, venereal disease, mental deficiency, orthopædics including all fractures, and unstabilised diabetes

137 We consider that the only serious risk of the health centre system is that it may lead to bickering and quarrelling among the home doctors working there Nevertheless, the advantages, both to patients and staff, which it offers, greatly outweigh this risk The fact that there will be a similarity, if not an equality, of remuneration, and that remuneration will be related to work done, will greatly help matters, and as more of the higher income patients elect to enter insurance practice, the volume of extramural private work will become very small With a certain amount of goodwill we see no reason why the rivalry inside the health centre should not be confined to healthy and stimulating competition

XV Specialist and Hospital Services

THE HOSPITALS

138. An adequate hospital and specialist service must provide the following facilities —

(i) Consultation in clinics reasonably near the patients' homes, and, when necessary, consultation in the patients' own home

(ii) Outpatient treatment for conditions beyond the scope of the home doctor

(iii) Inpatient investigation and treatment

(iv) Special treatment for long lasting and chronic illness

(v) Rehabilitation (positive convalescence)

(vi) Training of doctors, nurses, and ancillary health workers

(vii) Research

139 An exhaustive examination of the disadvantages of the present system would be redundant, since most of them are generally admitted, but the following brief summary is necessary if remedies are to be applied —

(i) There are great inequalities in the service, conditions, and facilities offered to patients At one end of the scale are the best voluntary and municipal general hospitals, at the other are certain remote provincial voluntary hospitals, cottage hospitals, nursing-homes, and municipal fever hospitals, in which one would not wish one's worst enemies to be patients

(ii) There are equally great variations in the conditions of services of doctors, nurses and other staff

(iii) There are great inequalities in the conditions of admission Voluntary hospitals in practice impose an elastic means test, while municipal hospitals impose a rigid geographical test In both, contributory payment is exacted according to capacity to pay, this payment is made during or after the patient's illness A special and peculiar admission test is applied in voluntary hospitals, particularly teaching hospitals, patients with rare, interesting, gross, or typical maladies are favoured in preference to those with common, mild or dull complaints; in non-teaching voluntary hospitals this is unjustifiable As a result, doctors in municipal hospitals are sometimes starved of interesting clinical material

(iv) There are great inequalities in the degree of privacy available for different social classes

(v) The length of time waited for admission by patients varies not only from hospital to hospital, but also from department to department within one hospital It is usually longest for gynæcological and ear, nose, and throat complaints

(vi) The consultant services available for the poor at the voluntary hospital are in many ways admirable Consultant service for the poor in their homes is conspicuous by its absence The services available to rich may be even more admirable if they choose the right consultant in the first instance, they are however in grave danger of falling into the hands of pseudo-consultants medical rogues, charlatans, and tricksters, who exploit the Harley Street neighbourhood in the absence of any publicly recognisable guarantee of consultant efficiency The middle classes can obtain the same admirable service available to the rich—but only at a price which adds financial to physical distress

(vii) The conditions of work of the genuine consultant are such that 10 lean financial years between the ages of 25 to 35 have to be survived before a reasonable income can be achieved In this period, a certain degree of disillusionment with the high ethics and scientific standards of medicine is not unusual The difficulties of the young London consultants have been considerably increased of recent years by their rapidly multiplying number

140 In planning for the future, it is reasonable to try to pick out the best points of each existing hospital service and produce something which combines them all

(i) The voluntary hospitals have demonstrated the value of the parallel as opposed to the hierarchical staffing system of the municipal hospitals A ladder of promotion which forces the able clinician away from medicine, into administration, has little to commend it It is essential that the clinician should be on a par with the administrator Further, the clinician's opportunities should not be reduced because he specialises in something other than pure medicine or pure surgery

(ii) All specialist work should be done by specialists The cottage or small provincial voluntary hospital in which the GP surgeon practises occasional surgery is a danger to the public, not lessened because the public seldom realises the risks it runs

(iii) The number of changes of doctor which any patient suffers should be minimal As far as possible, persons seen as outpatients should be under the same doctor in the wards

(iv) The number of patients in the care of any doctor should be strictly limited, whether as inpatients or as outpatients Much poor work is done because the voluntary hospital outpatient doctor and the municipal inpatient doctor has far too many patients to attend to

(v) Single quiet wards should be available to all patients who need them for medical reasons Such patients should have first pick of the single rooms available Patients with a personal preference for single rooms should have their wishes catered for by a system of additional payment graded according to income, they should not be reserved for upper income groups only

(vi) All facilities needed by an inpatient should be available under one roof Few private nursing-homes provide all these facilities, and fewer still have a resident medical staff The facilities which are available to the poor in the voluntary hospital should equally be available to the rich

141 We are now in a position to outline our proposals for a national hospital service under the National Health Corporation The unit should be the region or subregion In an undivided region, or in a subregion, there should be 3 or more *key hospitals* We anticipate that the maximum number of key hospitals in the most populous region would not be more than 10 Except in very sparsely populated areas, no point in any region should be more than 50 miles from a key hospital Attached to each key hospital, there should be a number of *local hospitals* or *medical centres* No point in any region should be more than, say, 15 miles from a medical centre Attached to each medical centre should be the local health centres

142 *Medical centres*—These would be existing provincial voluntary, cottage, or municipal hospitals, often greatly altered in function and structure, and new hospitals built by the national health corporation All costs of these hospitals should be paid by the corporation Their functions should be allocated by the corporation

Indeed the ruralisation of town hospitals is a confession of failure of town-planning Since the local hospital will receive a continuous stream of outpatients and visitors, and since a booking system will distribute outpatient attendances throughout the day, the one essential for the site is that it should be very close to a good public transport service

159 It is equally important that key hospitals should be very close to a good public transport service since they will be nodal points for both patients, staff, and visitors, going to and from a wide area We consider that key *teaching* hospitals should certainly be urban , the life of a big town is in itself part of the training of the medical student For the rest, provided there is light, air, and quiet, we regard it as relatively unimportant whether key hospitals are urban or suburban We feel, however, that the case against the country key hospital—except in towns so badly built and planned that light, air, and quiet cannot be obtained—is valid The relative cheapness of country building sites is man-made and not a physically insuperable point And the contacts of town life add greatly to the happiness and efficiency of medical and nursing staff What holds for key hospitals holds equally for special hospitals

160 Long stay hospitals present a rather different problem In many of these, complete open air is essential Others have to provide facilities for open air work and colony life We think that the case for keeping them in the country, as at present, is good But great care should be taken in choosing sites for new hospitals to make sure that they are very near good public transport facilities

161 *Names of hospitals* —Great traditions of treatment, teaching, and research are bound up with the names of Britain's voluntary hospitals At all costs, these names should be preserved We consider that a purely geographical or functional name (except where sanctioned by time) militates against the growth of hospital corporate spirit We, therefore, hope that new hospitals will be given good names We deprecate also the numbering instead of the naming of wards A1 or B2 instead of "Charity" or "Dorcas" ward is a poor exchange

162 *Ambulance services* —Ambulances should be based on local and key hospitals and not run as a separate organisation Their present separation has arisen because of the divided control of the hospitals To make people work continuously as ambulance orderlies and ambulance nurses is to destroy any real interest in the sick which they may have

MEDICAL STAFF

163 We consider that the principles governing the work of senior medical staff should be as follows —

(i) All appointments should be advertised. Inbreeding should be discouraged, especially at teaching hospitals Primary selection should be by the medical committee of the key hospital concerned Final appointment should be by an appointments board composed of members of the regional office of the national health service of the regional medical advisory committee, of specialists in the subject concerned and possibly of additional assessors from outside the region Junior appointments up to registrar standard should be recommended by the medical committee, and confirmed by the regional office

(ii) The clinical and administrative ladders should be separate, and promotion and pay should be the same in both Movement from the one to the other should not, however be rigidly forbidden

(iii) No member of the senior staff should be confined to outpatient work, and none should be free from it The same applies to work at medical centres, and domiciliary consulting

(iv) The conditions of appointment, work, pay promotion &c , should be the same in all hospitals whether key, long-stay, special, or local medical centres

(v) Two types of appointment should be open to senior medical staff—whole-time and part-time Unless the post was specifically a whole-time one, as for example a university chair at a teaching key hospital or a research professorship at a special hospital, the choice of whole- or part-time work should largely rest with the candidate It should be open to him to revise his choice at not less than five-yearly intervals

(vi) Whole-time officers should have charge of larger units, with more beds and outpatients clinics than part-time officers They should be required to do domiciliary consulting under the national scheme for insured people, and should see and treat in small consulting-rooms and in single wards patients who had paid the additional insurance premium for private attention

(vii) Part-time officers should be permitted privately to see uninsured patients in hospital consulting-rooms, but not in hospital time—the fees to be collected by the social worker They should be permitted uninsured private hospital inpatients on the same basis, the hospital charging such fees as it deemed fit This would kill two birds with one stone consultation at hospital would be a guarantee to the patient of the efficiency of the consultant , and the pseudo-consultant would be left alone in Harley Street which would soon cease to have any cachet

(viii) At least one of the whole-time staff in each major subject in teaching key hospitals should be a university professor , this appointment should be made by the university concerned

(ix) Uniform national scales of remuneration for hospital staffs should be laid down We suggest the following approximate ranges —

(*a*) For whole-time seniors £1500 to £2000 , for whole-time deputies £900 to £1100

(*b*) For part-time seniors—if three quarters of the time, two-thirds the salary of the whole-time officer , if half time a third the salary of the whole-time officer We suggest less than a strictly pro rata basis, because we think men will only choose part-time work if they consider their earnings will thus be greater

(x) Adequate provision should be made for holidays, pensions on retirement and sickness

(xi) Movement from time to time within the hospital service should be encouraged, as also should travel at home and abroad, for the sake of gaining experience Such movement should not prejudice advancement, but rather the reverse

(xii) All senior hospital posts should be non-resident

164 For junior appointments, we propose little alteration in the existing procedure at voluntary hospitals We consider that every newly graduated medical practitioner should be compelled to hold a house appointment before being fully qualified legally Even with the present number of hospital resident posts, there appears to be no difficulty in this Indeed two compulsory posts is in fact physically possible The 1940 figures for England and Wales are as follows —

	Six monthly appointments	Total per annum
Voluntary teaching hospitals	87(+493)	1160
Voluntary non teaching hospitals	1048(+427)	2970
Municipal hospitals	712	1424
		5554

The figures in parentheses are for slightly more senior house appointments, all of which will presumably be filled by holders of junior posts If we assume that, in all 2000 posts will be filled by the promotion of those already holding posts, we are still left with 3500 posts per annum to fill The average number of doctors qualifying in this country per annum in the last 5 years was 1239 To this one must add, say, half the Scottish, Irish, and Colonials graduating here per annum, 570 (half the average for the last 5 years) Even so, there are enough resident posts to average out at about 2 per head

165 Every house-officer should therefore be encouraged to do more than one six-month house appointment Potential general practitioners, in particular, should obtain special experience of midwifery, pediatrics, and

senior, his deputy, perhaps a chief assistant, a registrar, one or two house officers, an almoner, as well as two or three clerks and secretarial assistants The number of hospital beds in each unit should vary from 40 to 80, depending on the type of work, and also whether the two seniors were part-time or whole-time Both seniors, the chief assistant, and possibly the registrar should do regular outpatient clinics at local hospitals (including the key hospital), and both seniors should have charge of beds in perhaps a ratio of two to three To each unit should be attached a number of single wards The number of units in a key hospital might be considerable For example, two general medical units (including gastro enterology and biochemical medicine as specialties), a cardiovascular unit, a pulmonary unit (including tuberculosis), a neurological unit, a psychiatric unit, an arthritic unit, a dermatological unit, a venereal unit, two general surgical units, an orthopædic unit, a genito-urinary unit, two ear, nose, and throat units, a plastic unit, an ophthalmic unit, two obstetric units, a pædiatric unit, two gynæcological units, and perhaps a children's surgical unit, might be a typical set-up There would be no rigidity in such an arrangement In one regional key hospital, for example, a plastic unit might be replaced by a neuro-surgical unit, and a general medical unit by an endocrinological unit Assuming an average of 50 beds per unit, a typical key hospital would have just over 1000 beds, plus its special blocks for fevers, minor illnesses and the chronic sick Pathology, radiology, anæsthetics and physiotherapy should constitute separate staff units Some regions at least should have one forensic medical unit

150 The administration of such a hospital should itself constitute a separate equal unit We regard it as unimportant whether the chief and deputy chief administrators are, or are not, medically qualified They should be administrative specialists, specially trained as such, and should certainly do no clinical work Where the senior administrative officers are laymen, routine medical administration should be in the hands of an RMO and RSO A hospital medical committee, composed of all heads of units and their deputies, should meet regularly to decide all medical problems We consider that representatives of the juniors in a key hospital, registrars, house-officers, and even clinical students, should sit on the medical committee We believe that this would have a most healthy effect in preventing staff squabbles, nepotism, and a general belief that the committee was acting only in its own interests Much of the committee's work would in fact be done by subcommittees It should make recommendations as to staff appointments to the regional authority, and these should seldom be disregarded In the event of conflict between the medical committee and the chief administrative officer, the committee should have the right of direct approach to the regional authorities

151 A similar nursing committee composed of the matron and representatives of the sisters and nurses and student nurses would be a desirable experiment

152 The lay committee or governing board should meet not more often than once a month It should be composed of existing members, whether of voluntary hospitals or local authority origin, plus medical and nursing staff representatives, and possibly one or two retired members of these staffs If it did not include members of a publicly elected authority, arrangements should be made for some general public or "consumer" representation It should receive the reports of the administrative officer and should deal with such other matters as was necessary

153 Where a key hospital was attached to a university or a medical school, these should be specially represented on the medical and lay committees Similarly the staff and hospital should be represented on the medical school committee

154 *Long-stay hospitals* —Attached to the appropriate units of each key hospital should be the necessary special treatment and convalescent hospitals These would be for pulmonary tuberculosis and other pulmonary diseases, cardiac invalidism (particularly for children), orthopædics (including accidents, and bone and joint tuberculosis), rehabilitation and convalescence of general medical and surgical conditions, intermediate and chronic mental illness, epilepsy, and mental defect Where new hospitals of this type were needed, it might be possible with profit to build combined pulmonary, cardiac, orthopædic and general country rehabilitation hospitals We think that such combined units would be profitable alike for patients, nurses, doctors, and students At each such hospital, the medical staff of the key hospital should have charge of at least a certain number of beds In addition, a staff of the house officer and registrar level would certainly be needed, and almost certainly higher specialist officers If more than two specialists were employed, a unit system should again be adopted, and exchanges of such specialists between the key and rehabilitation hospitals should take place at intervals If a medical superintendent was employed, the volume of his clinical work should be strictly limited, and visiting key hospitals and permanent specialists should be his equal in status

155 *Special hospital* —The specialised hospital, which concentrates on a single disease or group of diseases, is justified if it acts as a national centre of postgraduate teaching and research We doubt if there is room for one of each type of special hospital in each region We consider that specialised hospitals should operate on a national basis A great part of the present multitude of small specialised hospitals should be closed down, their staff and functions being taken over by the appropriate departments of key hospitals

156 We envisage two or three national special hospitals (of which one would usually be metropolitan) of each of the following types —

Pædiatric
Cardiological
Pulmonary
Neurological
Psychiatric
Dermatological
Venereal
Endocrinological
Gastro-enterological
Neoplastic
Traumatic
Orthopædic
Ophthalmological
Ear, nose, and throat
Midwifery
Gynæcological

Since these hospitals should exist primarily for postgraduate teaching and research, at least half the senior posts (arranged on the unit system) should be whole time, and often professorial The remaining senior staff might be specialists from adjacent key hospitals, but where this was the case the number of beds at the key hospital in the charge of the specialist should be appropriately reduced

157. It should be open to any doctor throughout the country to send a patient to a special hospital for consultation and treatment But the feeding of special hospitals with patients should more usually be done by affiliating them to one or more adjacent key hospitals The appropriate departments of these key hospitals would be correspondingly smaller Such a reduction would mean that some undergraduate teaching would be necessary at the special hospital, if the affiliated key hospital was itself a teaching hospital

158 *The location of hospitals* —Medical centres should be centrally placed in the locality which they serve, since —

(i) They would be general outpatient and emergency centres

(ii) The chronic sick, in particular, should be really near their friends

It does not necessarily follow that they should be in the centre of a town, though we see no inherent objection to this provided there is adeq

THE LANCET

LONDON SATURDAY, NOVEMBER 21, 1942

"THE END OF THE BEGINNING"

EVEN before the war, there were voices crying in the wilderness that all was not well with the medical services The burden of their cries was that preventable diseases were not being prevented , that the chances of avoiding death in infancy, in childbirth, from tuberculosis, and from rheumatic carditis were much greater among the rich than among the poor , that for most of the population such financial burdens were added to the burdens of ill health as to discourage early treatment , that the standards of treatment available in different places and institutions, and among different social classes, varied enormously , and that the income of those who cared for the sick ranged from the £40 plus keep and laundry paid to the probationer nurse to the £40,000 earned by the successful surgeon The whole picture was thrown into clear perspective not by a medical body but by a research organisation composed of sociologists, economists, and political scientists—in the PEP report of 1937 on the British Health Services The next milestone was the Government's noble miscalculation of the probable effects of enemy aerial bombardment From this sprang the first attempt at a national hospital service for the sick and injured The EMS was, and still is, a hotchpotch , but it has served its purpose, and has opened the eyes of many —among others, those of our special commissioner, whose plan for British hospitals filled our correspondence columns during the autumn and winter of 1939 Now, after nearly three years, we find the British Medical Association voting for a national medical corporation on just such lines as those which our special commissioner envisaged But that is jumping ahead

The lull in the fighting during the first winter of the war turned many people's minds away from the stalemate fronts to the future Looking back over the 1920's and 1930's was not a pleasant process for those with social consciences Few people really wanted to go back to the old ways But what was the right path to choose for the future ? The British Medical Association took the bull by the horns and set up a monster Medical Planning Commission There were many voices raised to deplore its procedure and composition ; but time proved their fears unfounded The BMA were not alone There were rumours of Royal College planning committees, students' planning committees, political planning committees and numerous discussion groups Many of these have foundered by the way, but this week we publish the results of one which has carried through the first part of its ambitious programme Medical Planning Research is not a LANCET sponsored body It is not a counterblast to the BMA Medical Planning Commission Its first aim, as set out in the medical press on its foundation, was to enable the "under 45's" to have their say, and special arrangements were made to overcome the war-time problems of geographical dispersal and inadequate transport But it was something more than a junior version of the Medical Planning Commission, as its report shows It took the patient as its starting-point, and not merely the patient in the surgery but the patient in his home It pledged itself to proceed by scientific methods Its attempt to analyse the problems of administration is something new in medical research It studies also the cost of health in relation to the national income and the national standard of living And it suggests a solution to the question of the future of the medical officer of health

The political parties have not been idle in medical planning, though so far the Conservatives have remained silent The Liberals have expressed themselves in 80 small pages[1] They adopt the health centre as the basis for general practice, a continuation of dual control of hospitals with state subsidies paid via the local authorities to the voluntary hospitals, and free treatment for all paid for out of general taxation The capitation fee is to be the basis of the GP's income, but private practice for both GPs and specialists is to continue Why anyone should pay for what he is entitled to receive free is not explained, for it is specifically laid down that the standards of treatment should be the same for all The Labour Party[2] are more concerned with social security than with the details of medical practice They look for a national medical service with salaried doctors for all, working through the local authorities The Communists[3] have confined themselves to practical proposals for increasing the immediate efficiency of the health services with a view to aiding production Finally, the Minister of Health himself[4] has assured us that the Government aims at supplying a comprehensive postwar hospital service to meet the needs of everyone, while retaining both the voluntary and the municipal services Payment by the sick of a proportion of the cost of treatment is to remain. Mr BROWN has so far not committed himself on the future of general practice, and it is reasonable to hope that his preliminary pronouncement on hospitals is a ballon d'essai rather than a final judgment The wise words of Sir WILLIAM BEVERIDGE have yet to see the light of day

There seems already to be general agreement—except in high governmental quarters—on many points the lower and middle income groups should have available a complete medical service, covering both home and institutional treatment, which should be paid for at some time other than during sickness , group practice and health centres should be the basis for a home doctor service, and the home doctor should take over the running of more of the special clinics now in the hands of whole-time municipal officers That looks like the end of the beginning, in the Prime Minister's happy phrase But some major questions remain to be faced and answered (1) Should the national health services be available to everyone regardless of income ? (2) Should the services be paid for by a contributory insurance scheme or out of general taxation ? (3) Should they be based on the local authorities, on a combination of voluntary hospitals and local authorities, or on a statutory national health corporation ? If general medicine As a rule, house-officers to special departments should first do a general post at their parent hospital or elsewhere All house appointments should carry a salary of at least £2 per week, in addition to board, lodging, and laundry Steps should be taken to improve the physical condition under which the resident medical staff live in many hospitals

166. The next step beyond the house appointment should be the registrar or alternatively, the assistant at a health centre These posts should carry with them a real living wage, if non-resident, of at least £450 to £500 a year

167. The next step, that of RMO or RSO at a key hospital or medical centre or of chief assistant in a special subject at a key hospital, should be a post of considerable responsibility If resident, its salary should be no lower than that of registrar If non-resident, the salary should be £600 to £800 a year From persons occupying these posts, the senior staff would as a rule be selected There is much to be said for a rigid rule that no senior should be appointed who had not at least 6 months' or a year's experience as an assistant at a health centre

xvi The Social Doctor

168 One of the defects of the British health services in the past has been the great gulf fixed between the curative services on the one hand (the home doctors and the hospitals) and the preventive on the other (the medical officer of health, the various health maintaining clinics, and the environmental services) The gulf was not lessened by the entry of the MOH into a partly proprietorial relationship with the municipal hospitals The successful MOH often suffers in much the same way as the senior medical officer of a municipal hospital, as he goes up the ladder, he gets further away from practical medicine becoming more and more a pure administrator Another defect of our piecemeal system is the overlapping of functions of county and other MOHs, particularly in rural areas Rural areas also suffer from the part-time MOH, a home doctor who combines his general practice with local authority work

169 We propose that the MOH, hereinafter called the social physician, for each area should operate from an office located in the medical centre His area of operation should be roughly that covered by the health centres working to the medical centre He will act as health adviser to all local authorities working within this area, and as adviser on environmental problems to all home doctors in the area

170 His field of work will be the health of his community as a whole, and especially the environmental factors concerned in health and disease

171 His first duty should be the organisation and maintenance of vital statistics and a medical intelligence service He should take over the function of the registrar, and should receive all notifications of births, marriages, and deaths This would avoid the unnecessary duplication of the present system In the case of doubtful death certificates, he would be in a position to clear the matter up with the notifying doctor He should receive notification of all infectious diseases, under him, a small team of social workers should be available for home visiting in connexion with infectious diseases The local hospital records should be in his charge, as also should the records of all the health centres in his area To deal with this material, he would need a trained statistical officer and a small statistical staff He should also have mechanical calculating machinery, so that all statistics could be transferred to punched cards, and sorted mechanically when necessary His weekly vital statistics should not only be forwarded to his regional headquarters and to the Ministry of Health, but also to every home doctor in his area

172 His second duty should be the organisation prophylactic health services Immunisation services he will operate through the health centres Maternity, child-welfare, school medical services, and factory medical services, he will operate similarly It will be his responsibility to see that the community is properly served in these respects If necessary it will be his duty to advise the establishment of new health centres

173. His present duties with regard to food and drugs, sewage and water-supply, housing and sanitation, should be unchanged

174. His conditions of service should be identical with those of senior officers at key hospitals His primary employer should be the regional office of the national health corporation His position vis à vis his local authorities would thus be greatly strengthened The social physician working at a key hospital would cover only the area drained by the key hospital in its function as a local hospital In teaching key hospitals, he might well also occupy the position of professor of social medicine

175 In each region or subregion, a regional social physician should act as regional coordinator He should, however, be equal with his peripheral colleagues and not above them

176. Social physicians should be appointed in the same way as other specialists and consultants

xvii Postscript

177 During the 18 months since MEDICAL PLANNING RESEARCH was launched there have been great changes, and many of the 400 members, particularly those in the Forces, have found difficulty in making the contribution they hoped, none the less more than 200 drafts have been received Those dealing with the general aspects of the subject have been used in preparing this report It should be understood that it is an interim report necessarily much shorter than the original contributions which have gone to make it It cannot be held to represent the point of view of all the contributors, the aim has been to select the more constructive proposal and those most calculated to attract constructive criticism It is in fact designed to test public opinion This phase was envisaged in the original scheme, in which critical as well as drafting members were enrolled Individual members' drafts were not written for publication, they were intended for private circulation to othe critical and drafting members, but the size of the schem and the large number of members who are now in th Services abroad has made private circulation virtuall impossible Since the contributions were not intende for publication and many contributions diverge i opinion it has been thought best not to publish the name of the contributors, among whom will probably be th most vigorous critics of the interim report It is hope that MEDICAL PLANNING RESEARCH is a medium by whic doctors and others serving in the Forces can contribut to the discussion of postwar health services Medic opinion is on the move, and no desire to suspend judgment can alter this fact It is important, therefore, th men in the Services should make their contribution now the anonymity of MEDICAL PLANNING RESEARCH ma make it possible for them to do so without conflictin with Service regulations

im under stress Many bad landers are suffering from a weakness of convergence, a condition eminently amenable to treatment, after which they experience no further difficulty In short, an inherited, constant or stable ocular muscle weakness is unlikely to give trouble, but a recently acquired heterophoria will so confuse the accurate judgment of distance as to make safe flying improbable In night approaching and landing, while stereoscopy is still necessary towards the finish when familiar objects are seen by the light of the flare path, the earliest phases of the approach are carried out by vertical parallax The pilot, circling the aerodrome to which he has been brought by blind-flying instruments, sees the flare path as a large T illuminated by separate and widely spaced lights He judges height and distance by the relative movement of these lights against each other He next turns towards the flare path on a bearing which will take him parallel to and just wide of the vertical limb of the T As he nears the ground the lights in the vertical limb seem to get closer together, until as he is about to touch down all of them will fuse into one Finally he ceases to group the lights as a system, but regards each as separate elements, gaining information about his final height from objects illuminated in the vicinity of each But something more is needed in a fast approach than the mathematical distribution of a series of lights There must be a suggestion of background and some familiar object dimly seen, otherwise attempts at landing are almost always too high, and it is here that a good night visual capacity will help the pilot Finally, although the rotating hexagon, depth-perception apparatus and other devices can detect those pilots who have no chance of achieving safety at night, they take little account of the two most essential qualities of all—confidence and morale These two qualities when present in good measure can make up for a host of small defects, and therefore no test must be allowed to overstep its usefulness and become an absolute standard by which this man is accepted and the next rejected

TAKING NOTES

IN the happy days when textbooks were few and duplicators had not been invented the student was largely dependent on his lecture-notes for reading material out of school hours But with modern facilities the medieval custom of note-taking is hard to justify NECHELES[1] of Chicago, speaking from a long experience of teaching physiology, maintains that 99% of his students used to write down what the lecturer said so arduously that they had little opportunity either to think or to grasp the significance of the subject Few teachers (or taught) will disagree with him After a hectic hour of illegible calligraphy the student leaves the lecture theatre with cramped fingers and confused mind, and even an evening of careful editing will not make his notes worth the time and trouble given to them Necheles has evolved a scheme of class secretaries which has stood up well to the key-test of examination results One or more students, depending on the size of the class, are asked to take notes of the lecture and elaborate them at home into a well-written paper This is then corrected and amplified by Necheles who adds the appropriate references to the literature, copies are then duplicated and distributed to each member of the class at a nominal price A different student is chosen as secretary at each lecture and the rest are asked not to take notes At the end of a course each student thus possesses a full and carefully edited set of notes which is of real value to him and, apart from the day or days on which he has acted as class secretary, he has been able to give his full attention to the lectures This is an elaboration of the plea made by a peripatetic correspondent[2] for a duplicated summary of the major points to be discussed at each lecture But unless such summaries were very full the student would probably still take notes, though not such copious ones An alternative method would be to interleave textbooks with blank pages which the student could take to the lecture and use for jotting down an occasional sentence amplifying what was already in the textbook This scheme would necessitate a complete programme of the lectures being available in advance Yet another useful procedure would be to issue the class with copies of any charts or diagrams used to illustrate the lecture which were not easily accessible elsewhere It is up to lecturers these days to support any labour-saving device of this kind which will smooth the path for the over-pressed student

Annotations

MEN IN CHANCERY

OUR peripatetic, returned from captivity, tells of wounded prisoners left behind at Dunkirk (p 627), of good conditions and bad, of courage and disappointment—especially that catastrophic disappointment when hopes of an exchange of prisoners failed Prisoners in good health need extra food, books, papers, games, sick and wounded prisoners need invalid foods, and the doctors taken with them must have drugs, instruments and medical books if they are to do the best for their patients The Red Cross and St John Ambulance Societies have these needs in mind, and are steadily supplying them as we at home give the means Those parcels of food are doing more than most of us had guessed, our peripatetic tells of measurable improvements in weight, vitamin-deficiency symptoms, hæmoglobin percentage and blood-pressure in our wounded prisoners after each distribution of parcels Such a target is worth as many direct hits as possible Donations can be sent to the societies at St James's Palace, London, S W 1

A PLEA FOR A CHAIR

THE Nuffield Hospitals Trust besides helping people to get into hospital is also ready to help people to stay out of hospital, and it is to this generous trait that the University of Birmingham is appealing through its vice-chancellor, with the support of its regional council, for a grant of £15,000 to provide the stipend of a professor of social medicine for the next ten years. If the money is forthcoming the university is ready to establish the new department at once, for it feels there is work urgently awaiting the chair-to-be. In a great manufacturing centre such as Birmingham many of the social problems are inevitably linked with industrial medicine and the department would probably begin by tackling these But the wider title which has been chosen would leave scope for discerning opportunism in its development Recent factory acts have given industrial medicine a new importance and many doctors and nurses are asking for post-graduate courses on the

the medical profession decides in favour of a corporation (and so far the BMA Commission and Medical Planning Research provide pointers in that direction), there is a tough fight ahead The local authorities exert much parliamentary influence, and the voluntary hospitals have many spokesmen in high places In resolving these difficult questions, the observations of Medical Planning Research on the burden of ill health in the upper income groups, on taxation *v* insurance, and on medical organisation and administration will repay careful study

NIGHT VISION AND THE PILOT

ALL eyes are blind in true darkness, but there is always some light in the wide spaces above us, even in the worst weather, and under optimum weather conditions the human eye can see a dark object in the night sky 1000 feet to 3 miles or more away Individual ability to see in the semi-dark varies greatly, and while this was merely interesting in peace-time it has now become of vital importance that those men with good night vision should be singled out from the rest Fortunately, we have had at the head of the eye department of the RAF a man who foresaw this development

"Dark-adaptation" is too narrow a concept to embrace those qualities which are required in a successful night pilot, for many factors are involved, and the whole is best summed up in the term "night visual capacity" In semi-darkness the rods take over from the cones and the area of maximum sensitivity of the eye then lies not at the fovea but 6° from it—just to one side of the object looked at If the rod mechanism is to work smoothly the pilot must be in good health and not fatigued There should be no anoxia such as might result from high altitudes or over-smoking, and no vitamin deficiency, though there are few young men in this country so lacking in vitamin A that their night vision suffers thereby If all these requirements are present, dark-adaptation will have reached a near maximum after 45 minutes in a darkened room and night visual acuity will then be at its best But more is required of the good night pilot than complete dark-adaptation Although much night flying is done by instruments these must be supplemented by vision in approaching and landing For the night fighter pilot time is short, and friend must be differentiated from foe He will require that mental alertness and extra analytical power that will appreciate the form and significance of a dimly seen object the fraction of a second before the other man Is there any test which will single out such a man from his fellows ? As long ago as 1935 LIVINGSTON devised the rotating hexagon, an instrument by which the night visual capacity of potential airmen could be estimated under something like service conditions The background illumination of this test was carefully controlled and could be varied to approximate to a starlit night at one end of the scale, passing up through bright moonlight to early dusk or dawn conditions As anyone will agree who has spent much time testing vision, each test is something more than an estimate of visual acuity, and the alert brain will usually manage to read an extra line Candidates for the hexagon test—so called because six panels of a hexagon are simultaneously illuminated and six candidates examined at once—wear dark goggles in a lighted room for half hour and then enter the darkened test-room, where they sit for a further 15 minutes while the test is explained to them in the following words, quoted from LIVINGSTON [1]

"You are each seated in front of a panel, which will be illuminated and will reveal certain objects and letters similar in character to those which you have just seen There are four tests, each corresponding to a metal button on your boards, and each is exactly similar in technique You will find the buttons placed in such a way that you can feel three in series, followed by a gap, and then a fourth button You will note that each button corresponds to a transverse grooved line on the Braille card As the buttons run down the middle of your boards, there is therefore a left and a right Braille line Each test exposes first objects and next letters On the left space, you will write the names of objects recognised If you cannot do this, endeavour to copy what you see On the right space you will set down what you can detect of the letters These should be so drawn that the upper group is above the grooved line, and the lower group just below it The letters may be set in abnormal positions Copy them as you see them Each test is of one minute's exposure and test succeeds test without intermediate pause On each occasion, the illumination will be slightly increased, till you reach the third test Between this test and the fourth you will be subjected to one minute of glare from an electric lamp suspended above the apparatus During this time you must not look directly at the lamp, but slightly beneath it After this you will be given your final test The examination is then over"

Top score in this test requires 32 correct answers, but the average score is 20 About 3 5% of personnel record 30-32 marks and 2 5% less than 2 marks Cases presented for examination that have a history of defective performance in night flying come almost invariably from the lowest group From these tests candidates fell into two groups In the first were those who, on being shown a dimly illuminated object, began a series of guesses until they hit the right answer The second group waited until the clues were clear enough for them to be certain of their answer All subjects in whom there was a suspicion of malingering returned a blank card

For night approaching and landing the pilot needs a well-developed stereoscopic vision At one time it was thought that the stereoscopic faculty was a birthright, that it grew to full fruition at the age of 7 years and could not thereafter be improved This is now known to be wrong The hold on stereoscopic vision varies greatly with individuals, and where it is defective the response to treatment is usually excellent It is true that many efficient pilots have not this faculty, or are even one-eyed, but these men have had the disability for many years and have had time to adjust themselves to it Certainly the difficulties of pupil pilots who cannot land their aircraft are often due to poorly developed stereoscopic vision If a man has binocular vision he will learn to use it in estimating distance by the sense of depth it gives him and by the degree of convergence required to focus an object with both eyes When he first takes to the air the stress of circumstances may cause his poorly developed stereoscopic vision to break down so that he becomes monocular His distance judgment fails him when he most needs it and he becomes a danger The man who never had stereoscopic vision will learn to make use of other aids—parallax, relative size of objects and so on—which, though less helpful, will not fail

In England Now

A Running Commentary by Peripatetic Correspondents

As an oxaluric myself I was very interested in the chemical confirmation in your last week's issue of my gastronomical researches. It started when I developed a horrid pain in London after the very poached egg on spinach lightly touched upon in your subsequent annotation. I had become fond of spinach while working (and eating) in Paris, and it never worried me there. So I took my pain and my problem to a colleague. He knew the answer because he too was an oxaluric subject and he avoided trouble by taking cream with his gooseberry tart. The spinach difficulty is entirely culinary. In France it is "creamed" with butter; in England it is served slightly damp. The point of all this lies in the application of the "strawberries and cream" principle to other oxalate-containing foods. Milk may be all right but rather dull. Cream and butter will do as well. Tomatoes need salad dressing (prewar). Mr Barratt has taught us why, and the answer is simply calcium. Well, well.

* * *

The story of the wounded who came back from Dunkirk has long been known. Far less is known about their more unfortunate brothers who, in addition to being wounded, had the misfortune to be taken prisoner. At a rough estimate there must have been some seven or eight thousand of them who lived to be taken into the hands of the German medical services. They were collected and housed in hospitals, schools, barracks and public halls throughout France and Belgium. There were British wounded in Rennes, Rouen, Paris, Lille, Bethune, Hazebrouck, Brussels, Malines, Zuydcote, Bruges, Namur, Ghent, Amsterdam, Enghien and many other places. The wounded remained in occupied territory for up to eight months, the last large batch to leave for Germany were the badly wounded of the 51st Division, who left France in late February, 1941. Stories from the different groups of men gave conflicting reports regarding their condition and treatment. It was my privilege, among many other doctors, to stay behind with the wounded, and during the first six months I worked under conditions varying from very bad to good. It is unnecessary to describe the appalling conditions which had to be endured during the days just before and after capture. Shortage of water, food and shelter was, in many places, acute, and that alone may indicate what hardships the wounded had to bear. Gradually conditions improved as they were moved away from the battle areas into centres where water, food and medical treatment were obtainable. In some cases the improvement was comparatively small—many spent three or four weeks on the same filthy stretcher and lived on a diet of black bread and beans. I remember arriving at a hospital one night with a convoy of 350 badly wounded cases. There was no room in the hospital, so the stretchers were placed in gutted sheds, and the only equipment with which we were provided during the night was one small saucepan of soup and three phials of morphia.

In early July, 1940, some fifty compound fractures of the lower limbs were sent to Brussels and I had the luck to accompany them. Here, we were received into a most efficient hospital with a bungalow pavilion to ourselves. There were separate eight-bedded wards, spring beds and a good operating theatre and portable X-ray apparatus. It was staffed by fully trained Belgian nurses. The food was excellent and the medical equipment good. The immediate improvement in the morale of the patients and in the healing of their wounds was as remarkable as were the conditions themselves. Two months later I left for Malines where some two hundred British wounded were housed in dark, damp barrack rooms. The food was quite inadequate and of poor quality. The patients were pale and solemn and their wounds showed little tendency to heal. Most of the wounded throughout the occupied territories were fed on a low maintenance diet which was far from sufficient to support the proper healing of wounds. They were therefore, dependent on their friends in the occupied territories for extra food. Thanks to the energy, ingenuity and courage of these people the goods were delivered. In most places the Germans forbade visitors or parcels to reach the British wounded; but this only stimulated the influx of the most nourishing food that could be found. A great deal is owed to the people of Northern France and Belgium who risked so much to save our wounded. Many stories of bravery and self-sacrifice could be told of women who feared nothing so long as their parcels reached the patients.

Gradually, as the war developed into a more serious affair for our opponents, those in the occupied territories were evacuated into lazarets and camps in Germany. Here, the conditions were uniformly poor. There was overcrowding and inadequate food and medical equipment. Nevertheless, the men rose to the occasion. Their morale was good. Physical training and rehabilitation classes were started and joints began to move for the first time in six months. The British Red Cross parcels began to arrive in January, 1941, and these did more than anything else in helping the wounded to get well. In one camp, charts of weight, vitamin-deficiency symptoms, hæmoglobin percentage and blood-pressures were kept before and after each parcel distribution. The results showed an astounding improvement at first followed by a steady improvement as other parcels arrived. Artificial limbs were made by our own men out of pieces of wood, plaster-of-paris, jam tins and other odds and ends. One noted firm known as Cook, Cripps and McDonald, in which Cook did the plaster work, Cripps the metal and McDonald the wood-work, made over a hundred artificial limbs. These were tough enough to allow the amputees to box or play football and basket ball.

In September, 1941, the Repatriation Scheme suddenly raised its fair head over the horizon, and all those—some 1400—who had passed the Mixed Medical Commission were collected together for going home. The centre rendezvous was a small village, and here the wounded spent three days and nights in an open field. Two long and well-equipped trains eventually arrived and a journey, which must have been one of the happiest ever, began. Each man was issued with a whole Red Cross parcel for two days, which was far more than enough. When the trains entered Belgium and later France the tracks were lined with crowds of people waving and giving the "thumbs up" and victory sign. Our men had not forgotten them. Now it was their turn to give to those who had helped them before. They threw the contents of their parcels into the crowds. This continued throughout Belgium and France. Handkerchiefs waved, kisses were blown and eyes were moist as the people stood three and four deep to watch the "Tommies" go past. Needless to say, everyone arrived in Rouen with empty haversacks and smiling faces. They eagerly searched for the signs of a boat but there were none. As days passed and no boat appeared, faces grew longer and longer. Eventually the truth was obvious, the disappointment colossal and once again our men had to swallow hard, pull in their belt, hitch up their wooden legs and say "C'est la guerre." During last December and February they left Rouen for Germany and Poland and once again said "Au revoir" to their friends in the occupied territories, but their spirit was fine and will last to the end.

* * *

He was old and very Scots, a neat and tidy figure in his Sunday clothes. The job he was after was that of a labourer in a Service establishment. He was somewhat unsteady in his walk and had a slight asymmetry of the features. He sat down and declared that he was in excellent health and very anxious to begin steady employment again. His systolic pressure was so high that my sphygmomanometer failed to register it, he had arteries like twigs, his eyesight was poor, and there was some weakness and wasting of his left arm and leg. Inquiry elicited the fact that he had suffered "a wee bit stroke" about eighteen months previously, but though it had taken a long time and a deal of perseverance he now felt as good as ever. His own doctor had warned him of his danger at the time of the stroke, but in spite of this and even though he received an adequate pension, his conscience worried him whenever he heard of the shortage of labour and so he thought he had better work. His failing eyesight and inability to do fine work with his left hand prevented him from continuing in his former skilled occupation, and so labouring seemed to him his obvious vocation. A breath of fresh air, thus, after the tales one hears about young adults claiming exemption from fire-watching and night shifts on flimsy pretexts.

subject The present week-end lectures and short certificate courses can only be a stopgap and do not acceptably meet what will probably be an increasing and continuous demand The university foresaw the need some years ago, perhaps too soon, for its department of industrial medicine failed—the vice chancellor suggests mostly through lack of sustained financial backing Its main source of income was annual contributions from industry, but Birmingham's experience suggests that these should be welcomed to supply the butter rather than to buy the bread If the trust sees its way to make the grant the new professor will know that his department has ten years in which to find its feet and prove itself indispensable to medicine and industry in the Midlands

ALIMENTARY HYPOGLYCÆMIA AFTER STOMACH OPERATIONS

AFTER gastrectomy and gastro enterostomy patients often show an abnormal glucose-tolerance curve, usually said to be due to rapid gastric emptying This curve, sometimes called the lag curve, rises higher, reaches a maximum later, falls more quickly and often falls to a lower level than the normal curve At times during this hypoglycæmic phase symptoms are complained of Do such hypoglycæmic symptoms arise in these patients after ordinary meals ? In an investigation in which many case-histories were taken and some hundred glucose tolerance curves plotted Evensen[1] set out to answer this question Of 38 gastro enterostomy patients 30%, and of 95 gastrectomy patients 15%, described hypoglycæmic symptoms during the test, compared with 6% of 50 normal controls and 8% of 50 patients suffering from non-operated ulcer More interesting still, 36% of the gastro enterostomy patients and 11% of the gastrectomy patients complained of hypoglycæmic symptoms after ordinary meals The symptoms were not unlike those of mild degrees of insulin hypoglycæmia—hunger, weakness, sweating, tremors, clouded vision, palpitations, paræsthesiæ and psychic disturbances in varying combinations and of varying intensity The symptoms appeared 2–3 hours after a meal and characteristically disappeared after ingestion of more food Nearly all the patients reported that strenuous or unaccustomed work shortly after meals predisposed to an attack Following up this point Evensen, in agreement with some other workers, found that the glucose-tolerance curve of normal people was much lower during even mild exercise, and he concluded that the performing of work after meals may be a contributory factor to the production of hypoglycæmic symptoms in patients after stomach operations The diagnosis of the condition presents no difficulties, once it is thought of, and the treatment is simple—rest and something to eat Even if untreated the attacks usually pass off in 10–20 minutes

FIFTY CLINICAL YEARS

THE transient and incalculable human body can always spring another surprise or two on its investigators We try to pin it down with our tests, we measure its functions more and more accurately, but it remains elusive—a whole which will not be confined to the parts so neatly docketed in laboratory and post-mortem room At the bedside a man of quick perception and long experience may come to be a good guesser, he may be able to predict things correctly about the human body (say) seven times out of ten He does it by relating the laboratory and X-ray findings in a given case to what he has picked-up, consciously and unconsciously, about sick people during his years of practice, and this ability is what we call clinical sense For fifty years the *Clinical Journal* has published the sort of articles which can help a man to develop this valuable quality—records of observation and experience which will join the data in the pigeon-holes of his mind and add to the of knowledge, remembered or forgotten, which n his judgment when he is considering a case The which now appears every two months, can look back a sound record Many eminent teachers have conti buted to its jubilee number, their names star the cov but we miss the name of the editor who can call so free on this galaxy of talent Dr J R T Conner has bee the guiding spirit of the *Clinical Journal* almost from t start and the sureness of his touch has become a by wor among his fellow craftsmen

KOILONYCHIA

SPOON nails are a classical *sign* in iron deficienc anæmia, and students are taught to glance at the nail while they take the patient's pulse Iron deficienc anæmia is commonest in women, and spoon nails ar therefore regarded as a feminine prerogative Th condition has been known for about 50 years, Croker i America used the term "spoon nails" in 1896, Heller i Germany introduced koilonychia in 1900 In 191 Knud Faber called attention to the frequent occurrenc of koilonychia in the then recently distinguished idio pathic hypochromic anæmia, and since that time it has become well established that koilonychia is part o the syndrome of microcytic anæmia, achlorhydria and glossitis which is seen particularly in middle aged women about the menopause and responds dramatically to adequate doses of inorganic iron The characteristic features are described by Clarke[1] of Boston as "an everted distal edge, flat lateral margins, and a spoonlike concavity of the finger nail" This striking change has received a lot of attention, but it occurs in only about a third of anæmic patients Women who have their hands in water a great deal, especially if alkaline washing materials are used, are said to be more liable to develop spoon nails and there is an impression that they are mainly seen in the charwoman class of patient Milder degrees of nail change such as brittleness or flattening are much more common That koilonychia is especially associated with iron deficiency receives confirmation from the observation of Swedish workers,[2] who, on the basis of serum iron determinations, detected cases of iron-deficiency without anæmia, three of their patients had koilonychia and in two the condition was cured by iron treatment Clarke has described an unusual case of koilonychia in a man with hypochromic anæmia A painter of 46 had a typical microcytic anæmia with achlorhydria, no evidence of lead poisoning or any other disease was found so he was given large doses of inorganic iron with excellent results and the koilonychia disappeared Seven years later he was seen again with a recurrence of the anæmia and koilonychia The anæmia was again typical, with a mean corpuscular hæmoglobin concentration (MCHC) of 24%, but ferrous sulphate in adequate doses did not increase the MCHC beyond 27%, nor did the koilonychia disappear Investigation showed some free HCl in the gastric juice after histamine injection, X ray of the alimentary tract was negative, but some chronically bleeding piles were discovered, after these had been dealt with further iron treatment restored the blood picture (MCHC 33%) and the nails to normal This case illustrates well the close relationship between koilonychia, iron deficiency and anæmia, and reminds us that this combination does occasionally occur in the male, and when it does that thorough investigation for causes of loss of blood is always necessary

URETHRAL ANÆSTHESIA

SIR,—The following method of anæsthetising the male urethra for cystoscopy or instrumentation may interest urologists

A special ball-ended needle made by Down Bros (*Lancet*, 938, i, 27 and 723, 1939, ii, 425) is lubricated and passed down the urethra into the prostatic segment The anæsthetic solution preferred is injected slowly by means of a Record syringe and the needle is then withdrawn gradually while light compression is exerted on the penis to prevent regurgitation of the solution. The needle is withdrawn until the ball at the end of it lies just internal to the external meatus, where it is left acting as a most effective temporary plug The syringe, which is left attached to the needle, is laid down in a convenient position on the table After five minutes the urethra will be satisfactorily anæsthetised and the needle can be removed The needle is passed with great ease and in the majority of cases the patient is hardly aware that the manœuvre has been carried out

This procedure is also of value in facilitating the passage of a soft rubber catheter in old men with acute retention of urine, especially those on whom previous attempts at catheterisation have been made before admission to hospital and who are in a state of defensive spasm

Romford D LANG STEVENSON

ANOTHER REASON FOR NOT SNEEZING

SIR,—Dr Theodore James's letter of Nov 7 interested me because two years ago it occurred to me that the initial sneezes preceding a cold might be a seed-sowing property of the cold virus and not a reflex effort of the host to throw off the infection, examples in nature are many from the common burr to the thistle-down. So it would be beneficial to thwart this attempt to disseminate the virus Since stifling these early sneezes I have been freer from fully developed colds for these two years than ever before, but I also take a large dose of bicarbonate of soda

Park Crescent, W 1 C B HEALD

EPIDIDYMITIS

SIR,—In your annotation of Oct 24 (p 490) the statement is made that gonorrhœa is the commonest cause of acute epididymitis Such a view is not borne out by experience Since the introduction of chemotherapy in the treatment of gonorrhœa, epididymitis has become much rarer, and in the pre-M&B days it was not a common complication unless too great a pressure was used while giving the urethral wash-outs In my experience acute epididymitis occurs most commonly in non-gonococcal (e g, *B coli*) infections of the lower urinary tract

St James Hospital, S W 12 HENRY K VERNON

THE AMPUTEE'S POINT OF VIEW

SIR —I should like to offer my respectful congratulations to the woman who " when her below-knee artificial leg was fitted was delighted to see herself in the glass standing on two normal and evenly shaped legs (*Lancet*, Oct 10, p 427) I underwent a through-knee amputation many years ago Ever since I have sought not an artificial leg that would permit me to dance as long as I liked but one that would enable me to do my work in comfort and security I have not found it Here are instances of what I have found the knee-joint of one leg has broken four times in the past ten years, and repairs during that time have cost me £22 10*s* In the same period repairs to another leg have cost me £6 One expensive leg fitted so badly that if I walked two miles on it the stump got raw My experience justifies my saying that an artificial leg is a crude nerve-racking contraption, costly to buy and costly to maintain

LPCPI.

ROYAL SANITARY INSTITUTE —Lieut -Colonel D J Anthony MRCVS, will deliver the Benjamin Ward Richardson lecture at the institute, 90, Buckingham Palace Road, London. S W 1, on Wednesday, Nov 25 at 2 30 P.M. He will speak on the state of meat inspection in Britain at war

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

WE had two King s Speeches last week one proroguing Parliament on one day and a second opening a new session on the next day The speech proroguing Parliament, which was read by the Lord Chancellor, dealt to the extent of six columns of Hansard almost entirely with the history of military operations and political arrangements between the Allies, the speech delivered by the King when opening Parliament was shorter, but opened up the larger political aspects of the world struggle, and will provide the opportunity for lively debates

This year the debate on " the humble address to be presented to His Majesty " is to be thrown open for two or three weeks, and there are already a number of amendments on the order paper and there will be debates on conditions in the services, on old age and widows pensions, on pensions appeal tribunals on equal pay for men and women on health and on the Atlantic Charter, as well as on the general war situation and many other special issues Prof A V Hill has sponsored the amendment on health questions which will range over a wide field from improvements in factory hygiene to immunisation against diphtheria An answer to a Parliamentary question shows that in only two county boroughs (Birmingham and Bradford) have at least half the children under 5 been immunised

During this debate the new regulation 33B under the Emergency Powers (Defence) General Regulations (see THE LANCET Nov 14 p 589) aimed at the control of venereal disease will be debated, probably with approval for the most part The procedure safeguards the medical practitioners concerned against action for defamation or breach of professional secrecy, and in view of the increase in venereal disease especially syphilis since the war began, it is not expected that any important section of opinion will object to the far-reaching powers conferred by the regulation, with the information thus obtained about the distribution of venereal diseases it should be possible to arouse the public conscience by well-directed propaganda on public health lines And here we can learn something from the Soviet Union, whose hygiene propaganda against syphilis and gonorrhœa has been as realistic as our own against diphtheria

The victories in Egypt and Libya and the successful developments in North Africa have produced in the House a more buoyant mood, but one in which political controversy is not likely to be entirely absent Sir Stafford Cripps has made it clear that " controversial legislation ' should be avoided but it is by no means certain that the House will agree It is felt that the preparations for victory having taken so long the preparations for a successful peace may also be lengthy More and more about the preparations for a successful peace and the firm foundations of reconstruction will be heard in the House and, as time goes on. more about health education and the social services, and the Beveridge report on all-in social security proposals

QUESTION TIME

Health of British in Hong-Kong

Mr R K LAW under secretary for foreign affairs, informed Sir JOHN WARDLAW-MILNE that from reliable first-hand evidence which had recently become available, it was apparent that conditions at the Stanley Internment Camp in Hong-Kong had considerably improved since the early days At the end of July the general health situation could be regarded as satisfactory There had been no major epidemics in the camp, though there had previously been some cases of a mild form of dysentery There had, too, been some cases of beri beri, which were being treated as well as possible in the absence of suitable drugs Medical supplies in general were running short and the International Red Cross Committee were doing their utmost to ship them to Hong-Kong There had been very few deaths in the camp and those that had occurred were due generally to organic diseases During July a medical examination had been made by a British doctor of all persons in the camp with results which showed a

Letters to the Editor

THE CHRISTMAS GIFT

SIR,—It is always with a feeling of hesitation, perhaps of fear, that I address this letter to you at this time of the year; hesitation and fear lest I should fail to state the cause effectively to your readers. But in my 25th year of office as president of the Royal Medical Benevolent Fund and as an old man myself, may I once more appeal on behalf of old doctors and their loved ones that the *Christmas Gifts fund be continued in 1942*. *A gift* of £2 to each of our beneficiaries on Christmas Day to bring some comfort, perhaps warmth or an unaccustomed enjoyment to homes where every penny has to be considered, is my desire. Will all friends who have helped me in the past do what they can again this year, and will others come forward as contributors to take the place of those who have had to drop out.

All contributions should be addressed to the hon. treasurer, Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, London, S.W.15, and cheques should be made payable to the "Christmas Gifts Fund."

THOS. BARLOW,
President, R.M.B.F.

CÆSAREAN SECTION AND THE CRUSH SYNDROME

SIR,—Mr. Paramore makes statements which should not go unchallenged. I have no views as to the causation of postpartum suppression of urine. This must be a rare complication "in women previously apparently well" unless an accidental hæmorrhage has occurred, and little precaution need be taken in midwifery practice to prevent it in the absence of pregnancy toxæmia or accidental hæmorrhage. Many of us however agree that there is a definite place for spinal anæsthesia in operative obstetrics, but this case can be spoiled by its injudicious use. Surely Thomas was right in deprecating spinal anæsthesia as the method of choice when antepartum hæmorrhage has brought down the blood-pressure very low—and even after transfusion. Mr. Paramore states that since 1929 he has always done the lower-segment cæsarean section. This operation was designed for cases of disproportion in labour; its application has been extended, but there are still indications for the classical operation. I did one a few months ago for a true case of locked twins and I would defy even Mr. Paramore to have delivered them by the lower segment.

I have seen very few cases suffer from shock after using a heavy spinal anæsthetic such as procaine, in the form of 'Planocaine' 5% 3 c.cm. Mr. Paramore's advice to put every patient after cæsarean section or forceps delivery under spinal anæsthesia into the Trendelenburg position is open to question. It is unnecessary and indeed negatives to some extent the virtue of the lower-segment operation which was intended to lessen the risk of infection of the peritoneal cavity and to allow of cæsarean section in cases suspect of infection. To withhold fluids as suggested and to restrict food after a cæsarean operation is unphysiological, means extra suffering for a thirsty patient, lowers resistance, invites infection and will imperil lactation. Mr. Paramore asserts that after he does a forceps delivery "no complication ensues when asepsis is assured." There must be many of us who can only hang our heads in shame to think of the occasional pyrexia, white leg, or even embolism, that some of our less fortunate patients have developed. Asepsis can never be "assured" in midwifery practice.

Carlisle. GEO. P. MILNE.

DIAGNOSIS OF BREAST TUMOURS

SIR,—An annotation in your issue of Oct. 3 (p. 402) referred to the work of Dawson and Harvey on the correlation of the macroscopic and microscopic diagnosis of mammary cancer. This paper showed that there was a high degree of accuracy of diagnosis by sight and touch in mammary cancer by the experienced surgeon and pathologist. In 111 cases where the whole breast was sent for examination following mastectomy there was only one in which an error in macro-diagnosis was made. In their commentary at the end of that paper they stated that "... rapid diagnosis by means of a frozen section or by staining the surface of an excised section of tissue adds little if any certainty in breast cases." Your annotation, however, sums up as follows: "It looks as though the surgeon should only send for microscopy those breast tumours about which he is doubtful." This is a very different matter, and it would not be in the patients' best interest if the result of Dawson and Harvey's excellent paper was to discourage surgeons from sending mastectomy specimens for microscopical examination.

The treatment of carcinoma of the breast is both a surgical and a radiotherapeutic problem. To the radiotherapist a careful microscopical examination of the mastectomy specimen is of great importance in deciding what postoperative radiotherapy is desirable. What he wants to know is not so much that the tumour, which was clearly a carcinoma macroscopically, was confirmed as such microscopically, but rather how that tumour was behaving in that particular patient, in what directions and by what paths it was spreading, whether it was probable that the whole of the cancerous tissue had been excised, or where recurrence was likely to occur. For this purpose detailed microscopical examination of tissue from the limits of the region excised, to see if invaded tissues have been cut through, is necessary. This goes far beyond a mere confirmation of a confident macroscopical diagnosis.

Far too little consideration has been given to the function of the pathologist in reporting the mode of spread and likely site of recurrence from an examination of tissues excised in the treatment of cancer. Such detailed pathological work carried out at this hospital has proved of great value in the planning of postoperative X-ray treatment. The pathologist is not merely a person who, by attaching a label to the case, allows of convenient classification, but an important member of a team which decides what treatment is required.

Royal Cancer Hospital,
Fulham Road. D. WALDRON SMITHERS.

*** We were thinking only of a short-term policy for *a period of pressure on time and staff.*—ED. L.

MALE NURSES

SIR,—My committee, an association run by Naval medical officers to help Sick Berth staff to find suitable employment on being discharged to pension, desire to draw attention to a source of supply of well-trained male nurses which appear to have been overlooked in the reports of the Athlone and Horder committees. Naval sick berth ratings are trained at the expense of the Admiralty, and efficiently carry out the sick nursing in Royal Naval hospitals, depôts and ships. The qualifications and Service examinations for promotion in no way fall short of the requirements for the certificate of the state-registered nurse. After at least 20 years service they retire on pension, and those who wish to make use of their training find themselves unrecognised as possessing any nursing qualifications. A letter to this effect has been sent to the Minister of Health. Many medical men at present serving as temporary Naval medical officers must have felt the advantages of having such reliable, capable and experienced sick berth ratings to assist them. These men should be given a definite status in any Nursing Act that may come into force.

J. FALCONER HALL,
Hon. Secretary, Central Council, Royal
London, N.W.6. Naval Sick Berth Staff Associations.

R.S.M.: OBSTETRICS

SIR,—May I correct the false impression made on some of your readers by the report in THE LANCET of Oct. 13 (p. 511–512) of my contribution to the discussion on Oct. 16 at the meeting of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine? Far from accepting the conclusions of the work of Ebbs and Tisdall in Toronto, I pointed out that the controls were not comparable to the subjects of the experiment and that the conclusions in regard to infantile deaths were valueless. I did not say that I thought the number of cases investigated in the research sponsored by the People's League of Health was too small, though I consider the conclusions drawn by the authors of that work are not warranted.

Harley Street, W.1. DOYNE BELL.

e Thrimble in 1887 and they had three sons and a ghter Their second son, Dr E R C Walker of rdeen is now a prisoner of war

STANLEY WALTER PRATT

LOND , SURGEON LIEUTENANT R N V R

Lieutenant S W Pratt, who was reported presumed killed," after the loss of HMS *Dorsetshire*, in the Bay of Biscay last April, graduated from University College Hospital in 1936 A fellow student writes "Stanley Pratt worked with enthusiasm and energy, being specially interested in surgery and obstetrics, and he also took a great interest in the social and sporting activities of the college and hospital He played rugby regularly and also a good deal of lawn tennis and squash He was an understanding and sympathetic companion, and his sense of humour was com- ed with an acute perception which made his friendship uable" After qualifying Pratt held house appointnts at his own hospital and at Leicester Royal irmary He joined the RNVR in May, 1940

WALTER TYRRELL BROOKS

M A OXFD, M B LOND

T is now some years since Dr Walter Brooks retired l slipped quietly away from Oxford with his best work acclaimed But he is not forgotten there and many his friends, especially at the hospitals, when they heard his death at Swanage on Oct 14 gratefully recalled a od life spent in helping the sick of yesterday, today and morrow Brooks was born in London in 1859 and m King's College School he went to Christ Church, ford, and obtained his MA degree before returning to ndon to study medicine at KCH He qualified in 82 and a year later graduated with honours in medicine d set up in practice at Oxford Soon afterwards he s appointed to the staff of the Radcliffe Infirmary, but s outlook always remained that of the loved and trusted mily doctor rather than the hospital physician To e children at Lynams and Radley, where he was for ars school medical officer, and to the undergraduates Brookie" was more like a friend than a doctor, and ith his wide circle of friends it was no wonder that he as elected a university coroner after a contest with a ughty opponent His administrative work left a real lough unappreciated mark on the town After the st war, during which Colonel Brooks served as officer-in- arge of the medical division of the 3rd Southern eneral Hospital, he was appointed administrator under e Ministry of Pensions of the Wingfield Hospital, and y his astute strategy he later secured this hospital at mall cost as the permanent centre of orthopædic surgery n the district He was also vice-chairman of the adcliffe for some of the most important years of its istory, and loyally supported Mr Cronshaw in developng its work and in founding the Osler tuberculosis pavi- ion and the Sunnyside convalescent home Brooks was good churchman and a still better Christian gentleman

E M

Dr THOMAS STANISLAUS McMANUS has died in Salisbury, Southern Rhodesia Born at Cavan he graduated MB NUI from University College, Dublin, in 1928 After holding appointments at All Saints' Hospital, London, St Mary's, Plaistow, and the Miller General Hospital, he spent some years in America before he finally settled in Salisbury in 1937, where he quickly won a reputation for medicolegal work He leaves a widow and an infant son

---

The London County Council have opened their hospitals to medical visitors to this country who are in the forces, and Service doctors or nurses from overseas who would like to visit LCC hospitals or stay there during short leave should get into touch with the Medical Officer of Health, London County Council, County Hall, S E 1

Notes and News

THAT INWARD EYE

THE 74,000 blind people in England and Wales are a genuinely cooperative society the blind help the blind in ways that the old saying overlooked , and of course they have many sighted friends too The annual report of the National Institute for the Blind tells of bombed homes here and there, of difficulties about paper, the loss of a million gramophone needles and a few other hitches incident to war , but it tells too of work maintained, difficulties overcome, postwar plans already germinating and, above all, of the cheerful and spirited confidence of the blind which is always such an eye-opener to those who can see From the presses at the National Institute, Braille books, periodicals and music spread to the whole country and even still, though in limited quantity nowadays, to far corners of the empire At Brighton, Moon books and periodicals—easier for old people to read than Braille—are sent not only to English blind but to those in America Then people with a Talking Book machine can listen to books recorded on gramophone discs by first-class readers , and wireless sets are distributed to those who lack them, as well as any other personal help that is needed The institute's school of massage stands in Great Portland Street Sunshine Homes for blind babies are at East Grinstead and Leamington , the one at Southport was bombed, but a new one is being opened in Northumberland At Worcester College and Chorley College blind girls and boys of promise get their chance of higher education , and there is a home in Devon for those who are backward as well as blind There are homes for the old, holiday homes, convalescent homes, homes of recovery, and a new venture is a home where married couples of whom one partner is blind can live and work Among the homes of recovery for war-blinded civilians, America Lodge was the gift of the Blind War Relief Society of America to the British blind Captain Sir Beachcroft Towse, VC, chairman of the institute, is confident that friends of the blind will go on helping them , and he has a long experience to confirm him in that belief

HOME GUARD

IT was stated in our Students' Guide (*Lancet*, Aug. 29, p 251) that if a HG medical officer "cannot reach the aid post or hospital, or is not needed there, he is at liberty to report to his battalion headquarters, which means that he will come under the orders of the battalion commander and will in effect be mustered" We understand that this is not strictly correct The Army Council instruction runs "Where these civil duties permit they will keep in touch with their respective units and sub-units, rendering such service as they can" HG doctors are not, in fact, mustered in these circumstances and their prior duty is still to their civil commitment to which they may return at any time Moreover, every HG medical officer, whether mustered or not, is eligible for disablement or pension if he suffers an injury attributable to HG service

---

Royal Society of Medicine

On Monday, Nov 23, the section of odontology will meet at 4 30 PM, to discuss the treatment of pulpless teeth The openers are to be Mr W Stewart Ross, LDS, Mr A Bulleid, MRCS, LDS, Prof W E Herbert, MRCS, LDS, and Mr R G Torrens, B Dent Sc On Nov 24, at 5 PM at the section of medicine, Lord Horder, Surgeon Captain Desmond Curran Brigadier J R Rees, Group-Captain R D Gillespie and Dr W Fairlie will open a discussion on functional nervous states in relation to service in the Armed Forces On Nov 26, at 4 30 PM, the sections of urology and neurology are holding a joint meeting when Mr F J F Barrington, Mr John Everidge, Mr Clifford Morson and Brigadier George Riddoch are to speak on treatment of the paralysed bladder At the section of disease in children at 2 30 PM on Nov 27, Sir Arthur Hurst, Dr G W Bray, Mr James Crooks, and Dr C H Rogerson will open a discussion on asthma in childhood At the same hour, Dr A H Gale will read a paper to the section of epidemiology on variations in the mortality and incidence of the common infectious diseases in childhood over a century great improvement in health since May, when the conditions were at their worst There had been two medical surveys of the children in the camp The first survey in April/May had given an unsatisfactory result The second, in July, showed a great improvement, thanks to the successful efforts of the camp welfare committee in procuring food, including milk, to supplement the children's rations Food was quite inadequate at first, but there had been a marked improvement from May onwards, when flour was given in substitution of part of the rice rations A canteen has been functioning where cereals, tinned meat and fish, dried fruits, tea, coffee, cocoa, jam and powdered milk could be obtained in limited quantities Although the extremely bad conditions which prevailed at first had been confirmed, it was clear that there had been a marked improvement since May, particularly as regards food and health The recent arrival of 1000 tons of supplies, including clothing, should result in a further improvement

Air Ambulances in the Middle East

In answer to a question Sir ARCHIBALD SINCLAIR stated that in the Middle East, as in other theatres of operations, the evacuation of wounded or sick by air from the battle areas is undertaken by the Royal Air Force Specially fitted transport aircraft are normally used for the purpose

Tuberculous Nurses

Mr J H WOOTTON-DAVIES asked the Minister of Health (1) whether, in view of suggestions that girls should be compelled to take up sanatorium nursing and of the effort now being made to increase the number of nurses in such sanatoria, he would investigate existing cases where nurses had contracted tuberculosis in the discharge of their duties and were now maintained either by public funds or on a sum which did not permit of adequate and proper care, and (2) what steps were taken by his department to ensure the rehabilitation of nurses who contracted tuberculosis when nursing tuberculous patients, and whether he was satisfied that sufficient financial provision was made for such a nurse to ensure adequate food and clothing and a room apart from the rest of the inmates of the house where she might be more or less segregated —Mr E BROWN replied I would in the first place call attention to the statement in the recent report of the Medical Research Council that evidence from research in other countries and expert opinion in our own suggest that the risk of contracting tuberculosis from nursing tuberculosis patients in sanatoria is no greater than that involved in general hospital nursing A nurse in a tuberculosis institution who contracts the disease is customarily given every care and attention appropriate to her condition by the institution Arrangements for care and after care, directed to restoring working capacity, are an essential part of the tuberculosis service and apply to nurses as much as to any other person who has suffered from tuberculosis

Vitamin-B_1 Content of the Wheat Berry

Sir ERNEST GRAHAM LITTLE asked the Parliamentary Secretary to the Ministry of Food whether his attention had been directed to the claim by his chief scientific adviser that the bulk of vitamin B_1 content of the wheat berry lay, not in the germ, but in the thin skin covering it, whether his suggestion that much of the germ could with advantage be eliminated from bread, indicated any departure from the policy that national wheatmeal should contain the maximum quantity of wheat germ which, having regard to the type of milling plant, could be included, and whether he would re affirm that specification —Mr W MABANE replied My attention has been drawn to the remarks made by the ministry's scientific adviser in his recent Harben lectures at the Royal Institute of Public Health which included reference to a recent discovery that a large proportion of the vitamin B_1 of wheat germ is contained in the scutellum which forms part of the structure of the germ itself There is no intention at present to modify the existing instructions to millers regarding the manufacture of national flour

---

Messrs PHARMACEUTICAL SPECIALITIES (May & Baker) inform us that their product 'Thiazamide' and its sodium salt are now available for normal prescribing purposes Thiazamide is marketed in tablets of 0 5 g in containers of 25, 100 and 500, in bottles of 15 g of the powder, and in ampoules of the sodium salt (each containing the equivalent of 1 g sulphathiazole) in boxes of 6 and 25 ampoules

CHEMISTRY AND PHYSICS OF ANTISEPTICS IN RELATION TO MODE OF ACTION*

ADRIEN ALBERT, PH D (MED) LOND, B SC SYDNEY
OMMONWEALTH RESEARCH FELLOW DEPARTMENT OF ORGANIC CHEMISTRY, UNIVERSITY OF SYDNEY

THE ideal antiseptic is one that will actively inhibit the growth of bacteria in the presence of body fluids without injuring the cells of the host In view of the many ommon functions and components in living cells, whether human or bacterial, the problems involved in producing differential action of this sort are not likely to be solved easily or by purely empirical methods It is therefore regrettable that more research has not been directed owards the discovery of fundamental laws correlating physico-chemical properties with antiseptic action, especially as the few systematic investigations undertaken in this field have given results that, when collected and classified, fit into a logical and promising sequence

In the belief that the time is ripe for submitting the search for better antiseptics to that " rational approach " visualised by Fildes (1940a), it has been thought useful to review what is known about the nature of the chemical and physical factors believed responsible for the activity of antiseptics Experimental difficulties make the interactions of antiseptics with tissue cells rather difficult to determine, but much more is known regarding the effects of antiseptics on bacteria

HYDROGEN AND HYDROXYL IONS AS ANTISEPTICS

A good deal of evidence has accumulated that chemical reactions of a very simple kind play an important part in the action of antiseptics One of the simplest of these reactions is neutralisation of the free basic or acidic groups of bacterial protein Such neutralisation of vital functional groups seems to cause metabolic disturbances in the organism and eventually its death

Pioneer work on this type of antisepsis was done by Krönig and Paul (1897), who showed that the antibacterial effects of various acids were proportional to the concentration of hydrogen ions that they yielded While there are indications that an efficient antisepsis could be achieved in any tissue by bringing it to pH 5, even this mild acidity is apt to irritate and injure the host The epithelial cells lining the urinary tract seem least disturbed by such hydrogen-ion antisepsis, usually achieved by the administration of ammonium chloride or sodium acid phosphate This practice has its rational origin in the work of Shohl and Janney (1917), who showed that urine more acid than pH 5 inhibited the growth of *Bacterium coli* and other pathogens A high degree of alkalinity is also inimical to bacterial growth, but again it is only in urinary infections that this hydroxyl-ion antisepsis has found safe employment

More and more evidence is coming to hand that many antiseptics which function in neutral solution do so by forming un-ionised compounds with vital chemical groups in the bacterium Such complexes to be harmful to bacteria, must not readily dissociate into their constituents, and this suggests why the property of high molecular weight, which favours the formation of insoluble or feebly ionised complexes, is so commonly found in useful antiseptics This type of antibacterial action was definitely established by Fildes (1940b), who showed that inorganic mercurials are antiseptic because they combine with the sulphydryl (-SH) groups of metabolites (such as cysteine) that are essential for bacterial nutrition It will be interesting to see whether antiseptic salts of other heavy metals will be found to act in this way

ANIONIC AND KATIONIC TYPES OF ANTISEPTICS

As far back as 1924, A E and E W Stearn were postulating the formation of un-ionised complexes between antiseptics and bacteria in order to explain the varying antiseptic activity met with in salts that had one ion of much greater molecular weight than the other The Stearns recognised two classes of such salt, for which the names anionic and kationic antiseptics are now proposed

The *anionic antiseptics* are the neutral or faintly alkaline sodium (&c) salts of acids of high molecular weight, familiar examples being common soap, ammonium and calcium mandelates and a class of neutral, coloured substances known as " acid dyes " (e g , acid fuchsin) Stearn and Stearn (1924), who worked mainly with dyes, assumed that the coloured anionic antiseptics function through interaction of their acidic ions with the basic groups of bacteria to form feebly ionised compounds This conception could be further investigated and extended to the colourless members of the class, while the basic groups in question may be traceable to some particular bacterial enzyme system The postulated reaction, analogous to an ordinary double decomposition that results in precipitation, may be represented

$$P-NH_2 + Na^+A^- + H_2O \rightleftharpoons P-NH_3A + Na^+OH^-$$

where P stands for the main body of the protein, &c , and A stands for the anion of high molecular weight

Such a reaction is unlikely to take place to any extent in the absence of acid, and hence this form of antisepsis should be effective only at a pH value more acid than that of blood This is confirmed in practice, since anionic antiseptics have been found useless in infected wounds, moderately useful in skin sterilisation and very useful in the disinfection of the urinary tract, provided this is maintained sufficiently acid and the substances (e g , mandelates) are excreted unchanged

The improved action of certain of the above antiseptics in the presence of acid has sometimes been given a different interpretation—that the undissociated acid is more " active " than the ion This alternative theory would lose ground if it were found that increasing the acidic nature of the anions (in a related series of antiseptics) raises their antibacterial powers, as the converse behaviour of kationic antiseptics (see below) renders likely There are indications that the antiseptic activity of phenols is of the anionic type, but it seems preferable to deal with them after the discussion on surface-activity

The *kationic antiseptics*, which are the converse of the previous group, have found a much wider field of usefulness They consist of the neutral salts (hydrochlorides, &c) of bases of high molecular weight, and include all so-called " basic dyes " such as the polyphenylmethane antiseptics (brilliant green, auramine, crystal violet) and the acridine antiseptics (proflavine acriflavine 'Rivanol ') as well as the colourless higher aliphatic amines ('Zephiran,' 'Ctab' 'Quartamon ') Possibly certain organic mercurials of the type of phenyl mercuric nitrate also belong here since they possess kations of high molecular weight and do not readily liberate inorganic mercuric ions

Stearn and Stearn (1924) assumed that kationic antiseptics owe their activity to their basic ions, which they supposed interact with acidic groups in bacteria to form feebly ionised compounds (as in a precipitation reaction) thus

$$P-COOH + B^+Cl^- \rightleftharpoons P-COOB + H^+Cl^-$$

where P stands for the main body of the protein, &c , and B stands for the kation of high molecular weight

It might appear that this reaction would take place no more readily than the previous one, but certain factors favour it In the first place, bacteria contain an excess of acidic groups over basic groups, as is shown by their low isoelectric points Secondly, quite apart from -COOH groups, more strongly acid groups (phosphoric) are to be expected in the nuclear apparatus and enzyme systems of the organism This contention is supported by some recent work by McIlwain (1941), who finds that acriflavine inhibits bacteria partly through interaction with nucleotides

While the kationic antiseptics as a class have furnished some valuable agents for the prevention and treatment of sepsis in wounds and in the disinfection of skin and surgical instruments, individually they vary greatly in activity Three questions arise here · Why are some " kationic " substances not antiseptic , why are some kationic antiseptics comparatively ineffective against gram-negative organisms ; why are some members of this class (e g zephiran) rapidly bactericidal whereas most members are bacteriostatic with only a gentle disinfectant action ? These are stimulating questions and the collaboration of chemist and bacteriologist should answer them in the near future Meanwhile there are some highly significant clues

---

* Based on a lecture given to the Victorian Society of Pathology and Experimental Medicine in October, 1941

University of London

Sir Ernest Graham-Little has been reappointed chairman of the external council of the university for 1942–43

Medical Society of London

At a meeting of this society at 11, Chandos Street, W 1, on Monday, Nov 23, at 4 PM, Lieut Colonel E G Muir and Lieut -Colonel A E Porritt will open a discussion on surgery in the Middle East

Chadwick Lecture

Sir Arthur MacNalty will deliver the Malcolm Morris lecture on Tuesday, Nov 24, at 2 30 PM, at the Westminster Hospital medical school, Horseferry Road, S W 1 He will speak on the prevention of tuberculosis in peace and war

Royal Faculty of Physicians and Surgeons of Glasgow

Prof H J Seddon will deliver a John Burns lecture in the hall of the faculty, 242, St Vincent Street, Glasgow, on Wednesday, Nov 25, at 4 PM He has chosen as his subject recent work on peripheral nerve injuries

Medical Casualties

The following RAMC officers have been posted as prisoners of war

WS/Captain Harold Bloom, MRCS WS/Captain W E G Bradford MB LPOOL, Lieut Colonel W B F Brennan, MB BELF Captain L B Gunn, MB LOND, Captain P L Headon, MB NUI, and Captain L V Macdonald, MD ALBERTA

Bundles for Britain

London voluntary hospitals have received £93,442 and thousands of pounds worth of equipment from Bundles for Britain These American neighbours have now sent to this country over £170,000 in money, 17,000 cases of equipment, 25 ambulances, 120 mobile canteens and 185 blood transfusion sets

A Gift for Russia

The employees of Messrs George Gill and Sons (Sheffield) Ltd, in their own time are replacing 500 Spencer Wells forceps given to Mrs Churchill's fund and lost by enemy action

Royal Society Medallists

The King has approved the recommendation made by the council of this society to award a royal medal to Dr W W C Topley for his work on experimental epidemiology and immunology The Copley medal has also been awarded to Sir Robert Robinson, DSc, for his research work "which has influenced the whole field of organic chemistry", and the Buchanan medal to Sir Wilson Jameson for his administrative service to hygienic science and practice

British Standards Institution

This institution has been recognised by the Government as the body for the issue of national standards with the exception of those governed by the Therapeutic Substances Act and issued under the authority of the Medical Research Council and those contained in the British Pharmacopœia and the British Pharmaceutical Codex During the last twelve months the institution has published 160 new and revised standards, bringing the total issued to 1300

Presentation to Sir Alexander Macgregor

On Nov 7 the staff of Glasgow public health department met to present their chief with his portrait, painted by Mr W O Hutchison, ARSA The presentation was made by Colonel William Gunn, senior assistant MOH, and Lady Macgregor also received a gift of war bonds from Dr Nora Wattie, senior child welfare officer In thanking his colleagues Sir Alexander said he had tried to avoid over organising an administration that touched so closely the lives of the people He had never enjoyed leading strings himself The gathering was presided over by Dr R J Peters, deputy MOH

Flats for Disabled Ex-Servicemen

Since 1918 the Sir Oswald Stoll Foundation has run a block of residential flats at Fulham where disabled ex Service men may live at a nominal rental with their families while receiving the after care and special treatment they need Dr Lionel Bailey is the visiting medical officer and there is a residential nursing staff The foundation has secured the use of a country house rent free where some of the paralysed and helpless men have been evacuated Medical and nursing services are also provided there This war will increase the responsibilities of the foundation, and in their report for 1941 the council appeal for help in their work

CORRIGENDUM —In the article by T L Lawson (Oct 24, p 480) the chemical name of 'Pentamidine' should read 4 4'-diamidinodiphenoxypentane

Infectious Disease in England and Wales

WEEK ENDED NOV 7

Notifications —The following cases of infectious were notified during the week scarlet fever, whooping-cough, 965, diphtheria, 881, paratyp 6, typhoid, 6, measles (excluding rubella), 7384, pneumonia (primary or influenzal), 543, puerperal pyrexia, 140, cerebrospinal fever, 65, poliomyelitis, 18, polio-encephalitis, 1, encephalitis lethargica, 2, dysentery, 142, ophthalmia neonatorum, 76 *No case* of smallpox, cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 4 was 1734, including scarlet fever, 636, diphtheria, 251, measles, 197, whooping cough, 156, enteritis, 74 chicken pox 48, erysipelas 35 mumps, 22 poliomyelitis, 6, dysentery, 36, cerebrospinal fever 1, puerperal sepsis, 9, enteric fever, 3

Deaths —*In 126 great towns there were no deaths f* scarlet fever, 2 (0) from enteric fevers, 10 (0) from measles, 7 (1) from whooping-cough, 16 (1) from diphtheria, 56 (4) from diarrhœa and enteritis under two years, and 19 (3) from influenza The figures in *parentheses are those for London itself*

Thurrock and Preston each reports a fatal case of an enteric feve Sunderland had 3 deaths *from diphtheria Leeds, Liverpool* and West Bromwich each had 4 fatal cases of diarrhœa

The number of stillbirths notified during the week was 202 (corresponding to a rate of 35 per thousand total births) including 23 in London

SMALLPOX IN SCOTLAND

By Nov 11 sixteen cases of smallpox had been reported in the Lothians One middle-aged man has died from the disease at Tranent The outbreak has so far been confined to patients who have had direct connexion with the Edinburgh Royal Infirmary, or its convalescent home The infirmary has announced that outpatients will not be treated unless they have been vaccinated recently, and inpatients must have been vaccinated within the last six months Emergency cases will be admitted as usual but will be vaccinated as soon after admission as their condition allows

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Appointments

BECK, DIANA KINLOCH, MB LOND, FRCS neurosurgeon to the Royal Free Hospital, London
BERRY, N W, MRCS examining factory surgeon for Gosport, Hants
COCKSHUT, R W MB LPOOL examining factory surgeon for Hendon, Middlesex
PENTREATH, E U H MB LOND, DPM medical superintendent of the Mickleover County Hospital, Derbyshire

Colonial Medical Service —The following appointments are announced —

FLEMING, A McK., MB LOND, DTM&H MO at Kenya,
RAINSFORD O R C, MD BELF, DTM senior MO at Seychelles,
RUSHTON, E P K, MB BIRM MO at Sierra Leone

Births, Marriages and Deaths

BIRTHS

DICK —On Nov 7, at Bristol, to Dr Kathleen Dick (*née* Bates) and Major Cecil Dick RASC—a son

GORDON —On Nov 8 at Ipswich the wife of Lieutenant C J Gordon, FRCS RAMC—a daughter

HESKETH —On Nov 10, at Hitchin, the wife of Dr J S Hesketh—a daughter

HUGO —On Nov 11, at Guildford, the wife of Lieutenant Richard Hugo RAMC—a daughter

NORTH —On Nov 11, at Southport the wife of Surgeon Lieutenant John North, RNVR—a daughter

PARKES —On Nov 5, the wife of Lieutenant P W Parkes, RAMC, Bale Hall, Tamworth—a daughter

RODNEY SMITH —On Nov 10 in London, the wife of Mr Rodney Smith, FRCS, RAMC—a son

MARRIAGES

HANDLEY—GRAY —On Nov 12, at St Peter s, Vere Street, Richard Sampson Handley, FRCS, major RAMC, to Joan Gray, of Newcastle on Tyne

DEATHS

CHAPMAN —On Nov 10, at Bicester, Oxon, Herbert Frederick Chapman, MRCS formerly of Richmond, Surrey, aged 89

DAGGETT —On Nov 7 at Kirby Hill Boroughbridge, Henry Ingledew Daggett MB CAMB, aged 78

FLETT —On Nov 13 Alexander Flett, MD ABERD, DMRE, of The Avenue Bedford Park W 4

WORTHINGTON —On Nov 14, Helen Worthington BA Cincinnati, LRCPE

If we dare accept this suggestion that surface-activity s the *property* that converts a bacteriostatic into a actericidal agent, we shall need to know what chemical structure is responsible for this property and how it exerts its effects, desirable and undesirable

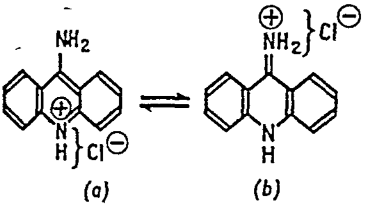

Fig 4—The two resonant forms of 5-amino-acridine hydrochloride (a) being derived from the amine and (b) from the isomeric imine

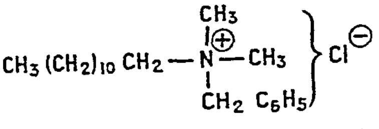
The property of surface-activity—that of congregating at a boundary—is due to a peculiar two-endedness of a molecule which must bear a powerful "polar-group" or "head-group" such as -COOH or $-NH_2$ at one end of its long axis while the rest of the molecule constitutes the "non-polar-group" or "tail-group" Such a tail-group is simply made up of carbon and hydrogens or halogens, and the longer and heavier it is the greater the surface-activity will be In essence this property is due to the "tails" being repelled by water while the head-groups cause the substance still to remain nominally in solution A slight variant of this type is provided by xanthates and similar sulphur compounds where the head-groups are attracted not by water but by certain solid surfaces



$$\left.CH_3(CH_2)_{10}CH_2-\overset{\displaystyle CH_3}{\overset{|\oplus}{\underset{\underset{\displaystyle CH_2C_6H_5}{|}}{N}}}-CH_3\right\}Cl^{\ominus}$$

Fig 5—Laurylbenzyldimethylammonium chloride (in Zephiran)

According to Rideal (1930) and Rideal and Schulman (1939), surface-active substances, whether foods or drugs, are attracted to the living cell and become orientated under or in it In general the "tails" of the foreign substances are anchored by the "tails" of the living membranes and in many cases the respective "head" groups are brought close together This mechanism could cause to concentrate, on or in the cell, substances essential to its metabolism or inimical to its very existence

As long ago as 1914, Berczeller noted that the phenols, an important class of disinfectants, were surface-active, the most antibacterial members proving the most surface-active It is regrettable that this correlation has not been sufficiently substantiated by test on a large number of phenols, but the results of Frobisher (1927) quoted in table II are highly suggestive Inspection of the formulæ of some 240 phenols, whose disinfectant powers are classified by Suter (1941), lends even more support to this hypothesis that bactericidal properties increase in proportion as the molecule assumes a definite "head and tail" arrangement

TABLE I—CORRELATION OF BACTERIOSTASIS AND BASIC STRENGTH AMONG AMINO ACRIDINES

Substance	Medium 10% serum-broth (pH 7 2)					Bacteriostatic index (sum of inhibitory dilutions)	Dissociation constant at 25° C $(\times 10^{-7})$
	Cl welchii	*Strep hæm A*	*Staph aureus*	*B coli*	*Proteus vulgaris*		
5-Aminoacridine	7*	6	3	3	4	23	300
2 8 Diaminoacridine (proflavine)	7	6	3	3	2	21	120
2 Aminoacridine	7	4	3	4	3	21	12
4 Aminoacridine	5	2	1	1	0	9	0 03
3 Aminoacridine	5	2	1	0	0	8	0 01
Acridine	3	1	1	0	1	6	0 002
1-Aminoacridine	2	1	1	0	0	4	0 001

* *Key to dilutions* 1 = 1 g antiseptic prevents growth in 5000 c cm of medium Similarly 2 = 1 in 10 000, 3 = 1 in 20 000 4 = 1 in 40,000, up to 7 = 1 in 320,000 0 signifies no inhibition at 1 in 5000

PHENOLS

The slight surface-activity of phenol itself can be greatly increased by inserting a hydrocarbon "tail" (as in 'Cyllin,' 'Izal,' and to a much smaller extent in cresol), or a combination of halogen and hydrocarbon "tails" (as in chloroxylenol, an active ingredient of 'Dettol') Table II further shows how the introduction of an alkyl group raises the bactericidal activity of a phenol until the chain exceeds five carbon atoms, when a drop in activity towards gram-negative bacteria (alone) begins

TABLE II—CORRELATION OF DISINFECTION AND SURFACE-ACTIVITY AMONG PHENOLS

Substance	Phenol coefficient		Surface tension of a 0 01% aqueous solution (dynes per cm)
	Staph aureus	*B typhosus*	
Resorcinol	0 3	0 3	76
4 Propyl resorcinol	3 7	5 0	73
4-Butyl resorcinol	10	22	66
4-Amyl resorcinol	30	33	60
4-Hexyl resorcinol	98	50	54
4 Heptyl resorcinol	280	30	43
4-Nonyl resorcinol	960	0	Not recorded

The surface-activity of phenols cannot in itself be responsible for their antibacterial action, so that evidence should be sought for an interaction between the -OH of the phenol and some characteristic group on the bacterial membranes It is true that this hydroxy group would not normally be classed as highly reactive, but Rideal has pointed out that reactions occurring with some difficulty in the bulk phase can take place with ease when the reactants are orientated in a surface-layer Even in 1934, Labes had found some evidence that phenols exert their disinfectant action through combination with the amino groups in bacteria, and he subsequently showed that even in the test-tube a phenol could precipitate an amine provided one reactant was of sufficiently high molecular weight or carried a lipophilic substituent If this is true, phenols are anionic antiseptics and it is not surprising that they have been found to act best in acid media Their own acidity is quite slight ($k_{acid} = 10^{-10}$), and, as Boyd (1915) showed, it is identical for all the common phenols It would be worth while examining phenols with enhanced and diminished acidity in order to correlate physical and biological properties more completely in this important series

The omega phenyl-aliphatic acids (from phenyl-acetic to phenyl-caproic) were capably investigated in 1931 by Daniels and Lyons They found that these substances were some 10,000 times more acidic than phenol and much more strongly disinfectant too, the disinfectant action increasing with the surface-activity which rose as the series was ascended

There are aspects of surface-activity which do not make it so desirable a feature in an antiseptic as may appear from the foregoing Since surface-active disinfectants act at great dilution in vitro, there is a danger that they are used in wounds at a low concentration that takes no account of their wastage through adsorption on the surface of pus cells, tissue debris and the like Protein in any form seems always to reduce the activity of surface-active substances and they seem always to be injurious to delicate human tissues

OTHER CHEMICAL MECHANISMS

The discussion of chemical action between antiseptics and bacteria has been confined so far to one type of reaction, neutralisation There are, however, other well-known types although these do not seem to be so suitable for further development

Formaldehyde appears to act by forming complexes involving the free amino groups of protein, but no other aldehyde has comparable antiseptic properties The halogenating agents, iodine, eusol and organic compounds liberating hypochlorous acid appear to act both by halogenating free amino groups and through a direct oxidising action There is also the group of frank oxidis-

As regards the first question, it seems that some kationic substances are not antiseptic because the strength of the free base is unsuitable The Stearns' hypothesis—“For any closely related series of dyes or other basic substances, the bacteriostatic power should increase with the basic strength”—was based on two premises First, that the ionisation of antiseptics would increase in proportion as the bases, of which they are the salts, became stronger and that this would increase the extent of interaction with bacteria, secondly, antiseptics derived from strong bases would form complexes with protein, &c most resistant to hydrolysis (Stearn and Stearn 1924) However, these workers also foresaw that it would be disadvantageous to work with the salts of too strong a base since these may not so easily produce un-ionised complexes

TRIPHENYLMETHANE DYES AS EXAMPLES OF THE KATIONIC TYPE

The Stearns sought confirmation of this hypothesis in the triphenylmethane series where basic properties were surmised to increase in the following order aniline blue, magenta, crystal violet (the so-called “gentian violet”), malachite green and brilliant green This is also the order of their activity as antiseptics Unhappily for this correlation, the basic strengths were not measured but were estimated from principles such as, “That the methylation of amines greatly increases their basicity” Since even aniline is now known to form an exception to this generalisation, it seems necessary to learn the basicities from actual physical measurement Unfortunately, the triphenylmethane dyes offer exceptional difficulties to the physical chemist in so far as the free bases are tautomeric and contain unknown amounts of colourless carbinols which are only feebly basic This state of affairs is illustrated in fig 1a and b Hence, in spite of previous work, this series would still repay investigation starting, perhaps, with compounds such as c (fig 1), where the addition of an inert *ortho* substituent counters the tendency to hydrol formation

The second question, why some kationic antiseptics are ineffective against gram-negative bacteria, may partly be answerable in terms of basicity Although all pathogenic bacteria are predominantly acidic, there is a notably different distribution of this quality among the common species At one extreme are gram-positive organisms such as staphylococci that have a high ratio of acidic to basic groups, while at the other extreme are the gram-negative types such as *Bact coli* Intermediate types are known and the two classes of bacteria actually merge imperceptibly into one another

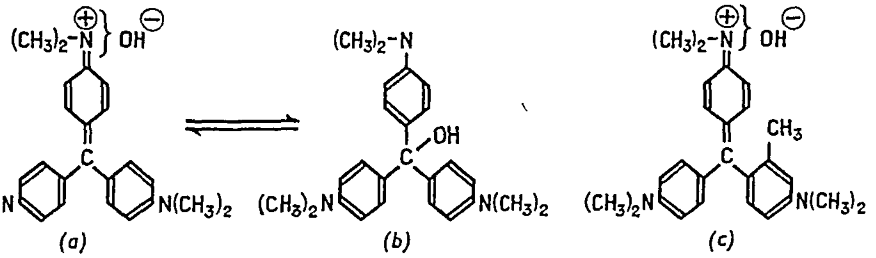


Fig 1—(a) Crystal violet (active base coloured) (b) Crystal violet (colourless carbinol) (c) Homologue of crystal violet The inert *ortho* substituent hinders carbinol formation

“There seems to be no essential difference between the mechanism of dyes as stains and as bacteriostatic agents,” wrote Stearn (1933), who interpreted the property of gram-positiveness as an avidity equally for *kationic microscopical stains and for other kations of* high molecular weight, gram-negativeness indicating a lowered affinity for both There seems to be an indication here that the high basicity requisite for antiseptic action is of *increased* importance in dealing with gram-negative bacteria

ACRIDINE DYES AS EXAMPLES OF THE KATIONIC TYPE

Since the best-known members of the acridine (fig 2) series (proflavine, acriflavine) show a high degree of toxicity to both gram-positive and gram-negative organisms and readily lend themselves to potentiometric titration, this has always seemed to me to be the group of kationic antiseptics most deserving of investigation from this angle Accordingly the antiseptic and basic acridine and all the mono-aminoacridines were c with proflavine (Albert, Rubbo and Goldacre Albert, Goldacre and Rubbo 1941) The results given in table I, where the relative basicities are as dissociation constants

Passing from the weakest base (1-aminoacridine) the strongest (5-aminoacridine) the antiseptic powers this series will be seen to increase in good accord with the Stearns' hypothesis Moreover, only the stronger bases are active against gram-negative organisms These measurements are being extended to a large group of acridine derivatives and the varying activities of the 50 substances so far examined are consistent with these two generalisations.

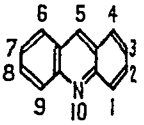

Fig 2—Acridine

It will be noticed in table I that while 1-, 3- and 4-aminoacridines are bases of about the same strength as acridine and aniline, 2- and 5-aminoacridines are some thousand times as strong This striking difference is readily explainable in terms of the theory of resonance. Resonance may be briefly defined as a low energy condition facilitated by certain structural peculiarities in a molecule and profoundly altering the reactivity of the latter in a way that is essentially predictable (see Sidgwick 1937) The structural peculiarities in the present case are tautomeric imine forms that can arise only when the amino group is in the 2- or the 5- position These imines, while unimportant in themselves, give rise to ions (figs 3b and 4b) that resonate with ions derived from the normal forms (figs 3a and 4a) This arrangement stabilises the ion relative to the base, making the latter strong

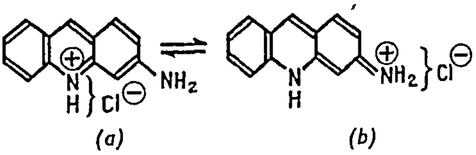

Fig 3—(a) The two resonant forms of 2 aminoacridine hydrochloride, (a) being derived from the amine and (b) from the isomeric imine

A similar arrangement is present in the *coloured* forms of the triphenylmethane dyes and it may safely be predicted that a vast number of new antiseptics will be found among such amines of high molecular weight as have highly resonant ions

The Stearns' prediction, that a very high degree of basicity will not necessarily be advantageous, is borne out in the acridine series, where the supremely high basicity of acriflavine and other quaternary compounds (equal to that of sodium hydroxide) has produced nothing superior to proflavine, which is no stronger than ammonia

LONG-CHAIN POLAR COMPOUNDS

In 1935, Domagk, who had just launched ‘Prontosil,’ discovered a new class of kationic antiseptics—quaternary aliphatic amines with a long lipophilic side chain as exemplified by fig 5, which shows the principal constituent of zephiran

It remained to Baker, Harrison and Miller (1941) to show that a wide variety of aliphatic amines have properties identical with this substance provided they are *furnished with a* side-chain from 12 to 16 carbon atoms in length Even primary amines showed high activity—e g, the lauryl ester of glycine These amines differ from acridine compounds in two ways their rate of kill is far more rapid but unfortunately they are much more sensitive to protein No explanation has been offered for this difference, which formed the subject of the third question May it not be a matter of surface activity? For, while the acridine compounds of table I have a compact structure and do not appreciably affect surface tension, zephiran, because of its “head and tail” structure, powerfully lowers the surface tension of water (from 75 to 39 dynes per cm at a dilution of 1 in 10,000)

TABLE I—DYSPEPTIC PATIENTS ADMITTED TO A ROYAL NAVAL HOSPITAL

Year	Quarter	Total	Dyspeptics		Ulcers*

* These figures include gastric and duodenal dyspepsia types 2 and 3 (clinical ulcers) If these are excluded, the figures are total ulcers, 471 (44 3%)

and barium-meal investigations were not, for various reasons, done in every case

For present purposes, war-time Naval personnel may be divided into two main groups : (1) active service Royal Navy ; (2) reserves and "hostilities only" (HO) personnel, some of whom are Merchant Service personnel taken over by the Admiralty Group 1 contained 217 cases and group 2, 786 cases, a ratio of 1 to 3 7.

In the following classification the term "operation" refers to all gastroduodenal operations other than those done for perforation.

Peptic ulcer gastric ulcer 67; duodenal ulcer 404, anastomotic ulcer 5 cases

Gastric carcinoma primary 0, ulcer-cancer 2 cases

All cases in these two classes were confirmed by radiological examination or at operation in this hospital, and the barium-meal investigations were conducted by one radiologist. Gastroscopy was performed in a few cases Cases of hæmatemesis or melæna are not included unless subsequently confirmed by X rays or operation

TABLE II—DIAGNOSIS AND PREDISPOSING FACTORS IN DYSPEPSIA CASES

—	Cases	% of total dyspeptics	Predisposing factors					
			A	B	C	D	E	F
Gastric ulcer	67	6 7*	5	23		4	1	
Duodenal ulcer	404	40*	35	82	5	9	37	
Anastomotic ulcer	5	0 5	-			-		
Gastric dyspepsia	30	3 0	1	5	1		1	1
Duodenal dyspepsia	148	15	10	28	1	6	9	1
Nervous dyspepsia	76	7 5	76	2	.	1	6	1
Reflex dyspepsia	14	1 3	-	-	-	-	-	
Dyspepsia of uncertain origin	221	24	1	84		11	9	5

A = psychological factors, B = food and diet C = alcoholic excess D = teeth, E = family history F = seasickness

* Excluding gastric and duodenal dyspepsia types 2 and 3 If these are included the figure for gastric ulcer becomes 9 3% and for duodenal ulcer 50%

Duodenal dyspepsia in which a clinical history suggesting duodenal ulcer was not confirmed radiologically during the present illness, 148 cases

Cases of duodenal and gastric dyspepsia (see below) can be further classified into three types as follows

1 No previous perforation, operation, hæmatemesis, melæna or positive radiogram, 48 cases

2 Definite previous operation for ulcer, perforation, hæmatemesis, melæna or positive radiogram, 66 cases

3 Radiological findings suggestive of ulcer or revealing healed ulceration, 34 cases Seven cases classed under type 2 showed type 3 characteristics, these are included under type 2 only.

Gastric dyspepsia, in which a clinical history suggestive of gastric ulcer was not confirmed radiologically during the present illness, 30 cases These can be classed like the duodenal cases as type 1, 4 cases type 2, 16, type 3, 10

It may be suggested that clinical distinction between gastric and duodenal dyspepsia is practically impossible, but the 4 cases classed as type 1 were considered to be typical of gastric dyspepsia in that there was much vomiting, fasting to relieve pain, aggravation of pain by food and considerable loss of weight From all clinical points of view the duodenal and gastric dyspepsias types 2 and 3 were cases of peptic ulceration and would have been included as such in a clinical survey. They were considered not proven from the statistical point of view and are not included among the confirmed ulcers. The effect of their incorporation in the respective ulcer groups is shown in tables I and II Radiological evidence of ulcer is defined as actual demonstration of an ulcer crater

Nervous dyspepsia, 76 cases Symptoms of dyspepsia associated with psychological abnormalities without clinical or other evidence of organic disease of the gastro-intestinal tract Most patients in this group were examined by a specialist in neuropsychiatry

Reflex dyspepsia, 14 cases Symptoms associated with definite and well recognised extragastroduodenal disease and cured by appropriate treatment Chronic appendicitis 8, chronic cholecystitis 1, chronic constipation 4, pulmonary tuberculosis 1

Achlorhydric dyspepsia, 4 cases

Hyperchlorhydric dyspepsia, 1 case

Fat dyspepsia, 1 case Fat intolerance without evidence of gall bladder dysfunction

TABLE III—AGE AT ONSET OF SYMPTOMS (YEARS)

—	Total cases	15 and under	16–20	21–25	26–30	31–35	36–40	41–45	46–50	Over 50	Uncertain
Gastric ulcer	67	3	5	5	21	14	6	4	4	0	5

Dyspepsia—											
Gastric	30	0	4	8	8	4	2	3	0	0	1
Duodenal	148	4	23	36	27	28	11	10	1	0	8
Nervous	76	1	8	13	21	10	14	4	1	1	3
Of uncertain origin	221	4	34	58	47	36	18	8	4	4	8
Alcoholic gastritis	17	0	0	3	3	3	5	3	0	0	0

Dyspepsia after partial gastrectomy for peptic ulcer, 3 cases.

Dyspepsia of uncertain origin, 221 cases This is a heterogenous collection of cases which do not conform to the characteristics of the other groups, and includes cases of so called "gastritis" with the exception of the alcoholic variety There was no evidence of ulceration in those who were radiologically examined, but some of them were probably dyspeptics with an organic lesion and should be included in the peptic ulcer group In 102 cases the symptoms were present for the first time and had begun since taking up service in the Royal Navy ; 82 of these were new entries and their symptoms had come on within a few months of active service life, the other 20 were regulars whose symptoms had started since the outbreak of war A well defined causative factor was present in 115 cases, 84 were due to alteration of diet, 11 to dental insufficiency and sepsis, 15 appeared to be sequelæ of gastroenteritis or acute tonsillitis and only 5 were attributed to seasickness Copious vomiting was a feature of 17 cases, with an excess of mucus in the vomitus Vomiting in greater or less degree is a definite characteristic of this group Gastroscopy in 7 cases showed normal appearances in 4, atrophic gastritis in 1, and hypertrophic gastritis in 2

Alcoholic gastritis, 17 cases

TABLE IV—DURATION OF SYMPTOMS

—	Total cases	Since war service	Years				
			3–5	6–10	11–15	16–20	21–25
Gastric ulcer	67	23 (33%)	15	16	3	5	0
Duodenal ulcer	404	52 (12%)	126	94	62	9	10
Gastric dyspepsia	30	6 (20%)	8	11	3	0	0
Duodenal dyspepsia	148	28 (20%)	55	36	17	5	1
Nervous dyspepsia	76	37 (49%)	23	12	0	0	0
Dyspepsia of uncertain origin	221	102 (47%)	48	35	18	3	6

Miscellaneous conditions aerophagy, 1, symptomless hæmatemesis, 1, duodenal ileus without characteristic symptoms 4, duodenal diverticula and long looped first part of duodenum with a mesentery were each seen in 4 cases but there was no evidence to attribute their symptoms to these conditions.

ANALYSIS

Each of the main groups has been analysed under the following headings category of service, age at onset of ing agents, ozone, hydrogen peroxide and permanganates All these substances are rapidly inactivated by protein of any kind and do not distinguish between bacteria and human tissues They sometimes effect instantaneous sterilisation, but when required to act over a long period must be constantly renewed The ingenuity with which this requirement has been met is exemplified in the Carrel-Dakin method of irrigation with hypochlorous acid and in the practice of giving hexamine when formaldehyde is required in the urinary tract

A more subtle type of oxidising effect was suggested by Dubos (1929) as underlying the antiseptic action of triphenylmethane dyes He credited crystal violet with maintaining the redox potential of the bacterial environment above a figure (+ 0 3 volt for aerobes) compatible with any of their metabolic activities Stearn (1930) criticised this view on the ground that crystal violet could hardly act as an oxidising agent at its extreme bacteriostatic dilution of one part in ten million, although, since there would be a hundred molecules of dye for each -COOH group present in the streptococci in his experiments, his acid-base hypothesis still held Later, Ingraham (1933) tried to reconcile these conflicting views by advancing a hypothesis that part of the action of crystal violet was due to its poising the bacterial environment at an E_H value too high for some phases of bacterial development Similarly, several attempts have been made to explain the action of sulphanilamide on a basis of redox interference, notably by Shinn, Main and Mellon (1939) and Burton, McLeod, McLeod and Mayr-Harting (1940)

While quinones as a class are both redox-active and antiseptic, and one quinone (citrinin) has been found to be the active antiseptic in a species of penicillium (Raistrick and Smith 1941), there is as yet no conclusive evidence of the extent to which antibacterial action can be attributed to interference with optimal E_H values

The most important group of antibacterial substances, the sulphonamides, lack general antiseptic activity. Their mode of action has been brilliantly illuminated by Fildes (1940a), who postulated that sulphanilamide exerts its action by displacing an essential metabolite, apparently *p*-aminobenzoic acid, from a bacterial enzyme, and this theory received further support when Rubbo and Gillespie (1940) showed that *p*-aminobenzoic acid was a growth factor for at least one bacterium More recently it has been shown (Albert and Goldacre 1942) that sulphanilamide has a basic strength ($k_B = 10^{-12}$) identical with that of *p*-aminobenzoic acid, and it may well be that this feeble basicity is significant in effecting similar chemical changes in both substances either before or after they enter the enzyme system

However this may be, sulphonamides represent a milestone in our progress towards ideal antisepsis since they make a refined and specialised chemical attack on a specific functional unit of the bacterium, as contrasted with the more generalised chemical activity of types described previously

SUMMARY

The nature of the physical and chemical factors believed responsible for the activity of antiseptics is reviewed Particular significance is attached to chemical activity of a very simple kind such as neutralisation and ionic exchange reactions The names anionic and kationic antiseptics are introduced to distinguish two important types of ionic exchange agents The discovery of many new antiseptics is predicted from considerations of modern theories of resonance

The possibility is advanced that high surface-activity is a property that promotes germicidal activity in disinfectants and is lacking in bacteriostatic agents

Some gaps in existing knowledge are indicated, the possibility of readily filling these by the collaboration of physical chemist, organic chemist and bacteriologist is suggested by what they have already accomplished

DYSPEPSIA IN THE ROYAL NAVY

STUDY OF 1003 CONSECUTIVE CASES

HENRY J WADE, M D MANC, M R C P
SURGEON LIEUT COMMANDER RNVR, MEDICAL SPECIALIST, ROYAL NAVAL MEDICAL SERVICE

(*From a Royal Naval Auxiliary Hospital*)

THIS review of cases of dyspepsia seen at a large N auxiliary hospital covers a period from October, 1939, to the end of September, 1941, during which 1063 (9% of the 11,564 admissions were diagnosed as dyspept The Army and the RAF contributed 60 dyspeptics to this series, for the purpose of this review they have been excluded, leaving a total of 1003 naval dyspeptics for consideration

During the first year of the war, as the number of admissions to hospital increased (table I) it became clear that the problem of the dyspeptic sailor was difficult. This applied particularly to those with a long-standing history of peptic ulceration, many of whom were discharged to duty after a long course of treatment and with advice as to subsequent dietary control It has now become evident that, in the vast majority of cases, expectations of relief of symptoms have not been realised

At a meeting of representatives of the medical sections of the various Naval hospitals held in the medical department of the Admiralty in March, 1941, it was recommended that cases of proved active ulceration and those with recurrence of symptoms, in the absence of radiological confirmation but with a definite past history of gastroduodenal operation, perforation or hæmatemesis, were to be invalided from the Service. Exceptions were officers and specialist ratings (key men) who could be usefully employed ashore in instructional or other duties under circumstances permitting adequate dietary control Such exceptions were each to be judged on their merits For the past 9 months these recommendations have been adhered to; a larger number of cases have therefore been invalided out of the Service in that time, but not because of any increase in the incidence of the disease There remain those complaining of dyspeptic symptoms for the first time, these are fully investigated and treated If the clinical findings are inconclusive and no definite removable predisposing factors exist, they are returned to duty for a trial period When there are definite predisposing factors, such as unsuitable food, gross dental sepsis or ill-fitting dentures, these are dealt with and the case again reviewed as to fitness for further service Should return to hospital be necessary and further investigation prove the presence of an ulcer, these patients are invalided Key men are discharged to shore service or invalided

Table I shows that the highest percentages of ulcer cases were admitted in the last quarter of 1939 and the last two quarters of 1940 (62%, 60% and 65%) These higher figures are due to new entries who suffered from peptic ulcer in civilian life and relapsed after a short period of active service Otherwise the incidence of ulcer cases among the dyspeptics admitted is remarkably constant (average about 55%)

CASES CLASSIFIED

In each of the 1003 cases all information likely to be helpful was carefully noted Fractional gastric analyses

magnified and new ones appear, it is natural to expect therefore that dyspepsia would increase. No confirmatory evidence of this can be found in the present work.

This review emphasises that the outstanding features of duodenal as compared with gastric ulcer are the earlier age of onset, the earlier onset of complications, the commoner family history of ulcer, and the greater incidence of psychological factors. Among patients under 20 there were 10 perforations and 7 instances of hæmatemesis in those with duodenal ulcers as compared with 3 perforations and 1 hæmatemesis in those with gastric ulcer.

The following questions need answers: Is dyspepsia (including peptic ulceration) increasing under war-time conditions in the Royal Navy, and what specific conditions, if any, may be held responsible for an increase in dyspepsia as a whole or an increase in any particular variety of dyspepsia? Examination of the large groups in this series shows a remarkably constant incidence when the ratio of active service RN to new entries is considered. The actual figures are: gastric ulcer 1 to 2.7, duodenal ulcer 1 to 3.5, gastric dyspepsia 1 to 2.8, duodenal dyspepsia 1 to 3.5, nervous dyspepsia 1 to 3.8, dyspepsia of uncertain origin 1 to 3.8. Considering the 1003 cases as a whole the ratio is 1 to 3.7. The expansion of the Royal Navy (more than four times its peace-time strength) since August, 1939, is more than sufficient to account for any apparent increase. Nor has there been any true increase in the percentage incidence of dyspepsia as a whole in the Royal Navy. The addition of new personnel derived from the prewar civilian population is responsible for the large number of dyspeptics admitted to Naval hospitals.

In answering the second question some observations may be made on nervous dyspepsia and dyspepsia of uncertain origin. Cases considered to be nervous dyspepsia have been investigated in consultation with a neuropsychiatrist. Nervous dyspepsia as here referred to is not a disease entity but a syndrome. It is not a gastric disease. Among new entries it has been found that cases of nervous dyspepsia associated with anxiety state are more numerous than in any other category (40 out of 76). The changed conditions from civil life to unaccustomed war conditions, particularly at sea, seem to have a deleterious effect on those who possess an unstable psychosomatic balance. It is well known that dyspepsia is the common complaint of the neurasthenic. War-time Service conditions do not lead to the feelings of comfort and peace of mind which are fundamental to normal digestion. Prolonged anxiety states would be expected to produce increased sympathetic tonus with a reduction of both stomach motility and gastric secretion, but gastric analysis in 35 cases showed no diminished acid secretion in 22 out of 35. Moderate hypochlorhydria may arise as a functional disturbance and depend on psychic alterations: there was hypochlorhydria in 9 cases only. Achylia gastrica was present in 4 but this condition cannot be considered as due to anxiety till anxiety symptoms were present.

A large number—175—patients with dyspepsia of uncertain origin had joined the Service since the outbreak of war. The evidence indicates that a complete change from the diet of civil life has produced symptoms. This applies especially to service in small ships where care in cooking is not always possible. Overcooking, reheating of meals, excess of tinned and fried food, short time allowed for meals, are factors difficult to control. Many of these patients had been accustomed to controlling symptoms in civil life by taking alkaline powders regularly. In a few cases an excess of alcohol played an important part.

SUMMARY

A series of 1003 cases of dyspepsia admitted to a large Royal Naval auxiliary hospital between October, 1939, and September, 1941, is reviewed.

There is no evidence that war-time service in the Royal Navy has increased the incidence of dyspepsia as a whole. The expansion of the Service and the inclusion of personnel from the prewar civilian population accounts for any apparent increase in incidence.

The relation of war service to the particular varieties of dyspepsia is discussed, especially with reference to nervous dyspepsia, peptic ulcer and dyspepsia of uncertain origin.

There is an urgent need for organised clinical research into all aspects of the problem of dyspepsia of uncertain origin (so-called "gastritis") which in the series accounted for 24% of dyspeptics.

There is a close similarity between the findings and those from other Service hospitals in regard to the ratio of gastric to duodenal ulcer and the percentage of duodenal ulcers in the dyspeptics admitted to hospital.

There is a long history in most cases; only 12% of the cases of duodenal ulcer and 20% of the cases of duodenal dyspepsia dated their symptoms from taking up war service, 62 out of 404 cases of duodenal ulcer, and 17 out of 148 cases of duodenal dyspepsia had symptoms for 11–15 years.

The early onset of symptoms and complications in cases of duodenal ulcer is noted.

Of the 1003 dyspeptic cases admitted 56% had clinical ulcers, in 47% ulceration was proved radiologically (6.7% gastric, 40% duodenal and 0.5% anastomotic), 15% were cases of duodenal dyspepsia, and 24% suffered from dyspepsia of uncertain origin.

Cases of proved peptic ulceration should be invalided from the Service unless there are exceptional circumstances under which adequate dietary control is practicable. In all, 329 of the 1003 cases in this series were invalided from the Service.

A statistical method of classifying dyspepsia which has practical value is presented.

I wish to thank Surgeon Rear Admiral H. E. R. Stephens for permission to carry out this work, Surgeon Captain W. I. Gerrard for his coöperation, Prof. R. S. Aitken for the gastroscopic examinations, and the Medical Director General of the Navy for permission to publish this paper.

RADIOLOGICAL EVIDENCE OF DECALCIFICATION IN SOUTH AFRICA

A. A. MEYER
MB CAPE TOWN, ADMR
RADIOLOGIST TO THE WOODSTOCK AND RONDELBOSCH HOSPITALS, CAPE TOWN

S. F. OOSTHUIZEN
MB CAPE TOWN, MRCPE, DMR
DEPARTMENT OF RADIOLOGY, GROOTE SCHUUR HOSPITAL, OBSERVATORY, CAPE PROVINCE

H. A. SHAPIRO, MB, PHD, CAPE TOWN
UNION HEALTH DEPARTMENT, CAPE TOWN

IN recent months slight changes have had to be made in our standard radiographic exposures which may have an important bearing on present-day nutrition. Our observations, which are not capable of being recorded statistically, have been made in two entirely different social classes: (1) private, reasonably well-to-do patients who can afford the fees of radiological investigation, derived mainly from the Cape Town urban area, but including about 25–30% of patients from rural areas, and consisting predominantly of Europeans; (2) public hospital patients, Europeans and non-Europeans, seen at the Groote Schuur Hospital at Observatory near Cape Town.

For the last 18 months there has been no change in our equipment—the same type of film has been used and the processing of films has also been rigidly standardised. In the last 4 to 5 months, however, we have been impressed by the fact that bone shadows in the films have been relatively often over-exposed. This fits in with the fact that the time required to show adequate bone contrast in developing the plates has often been shortened considerably, and we have had to reduce more films than usual. Quite often we have had to shorten appreciably the exposure used. For example, 18 months ago the standard exposure used by one of us (A. A. M.) in taking posteroanterior views of the normal male skull was 84 kVp, 60 mA, 7 sec. Now this is far too heavy an exposure and the factors have had to be reduced to 77 kVp, 60 mA, 6.5 sec. During the last 9 months a symptoms, duration of symptoms, predisposing factors, previous or present hæmatemesis, melæna, perforation or gastroduodenal operation for symptoms, fractional test-meal findings (the standard meal and histamine tests were both used in this series, and in every case of achylia gastrica the condition was confirmed by the histamine method), and disposal The ages at onset are shown in table III, the predisposing factors in table II, and the duration of symptoms in table IV

Gastric ulcer was found in 18 group 1 and 49 group 2 personnel—a ratio of 1 to 2 7 Of the 3 patients in whom the onset was before the age of 15, one began symptoms in his 13th and 2 in their 15th year Symptoms had been present for less than 2 years in 23, of these, 5 in group 1 had developed symptoms since the war began, and the remaining 18, in group 2, had developed them since their entry into the Service There were no cases of hæmatemesis or melæna in the series, but 6 had a history of previous hæmatemesis On admission 7 were cases of perforation, and 4 had histories of previous perforations Only 1 patient had a history of previous operation and 1 was treated by operation (excision) after admission Gastric analysis was performed in 31 cases of the 67, and showed normal acidity in 9, moderate hyperchlorhydria in 7, considerable hyperchlorhydria in 1, hypochlorhydria in 8, and benign achylia gastrica in 6 Two patients with the last condition were first suspected of having malignant disease, but proved to have simple ulcers On discharge from hospital 40 were invalided from the Service, of the 27 who returned to duty many no doubt will since have been invalided after being admitted to other Naval hospitals with a return of symptoms

* Confirmed ulcers

† Clinical ulcers, including gastric and duodenal dyspepsia types 2 and 3

Duodenal ulcer was found in 89 group 1 and 315 group 2 personnel, the ratio being 1 to 3 54 Of the 17 in whom the onset was before the age of 15, one was under 10, one in his 12th, 5 in their 13th, 5 in their 14th, and 5 in their 15th year when symptoms began Symptoms had been present for less than 2 years in 75 cases, of these, 23 had developed symptoms in civil life, 38 since entry to the Service, and 14 were group 1 men who had developed symptoms since the start of the war The high percentage with long-standing histories is noteworthy, only 52 (12%) out of 404 dated their symptoms from the time of taking up war service Hæmatemesis was present in 12 and melæna in 11, 34 had a previous history of hæmatemesis and 10 of melæna There were 12 cases of perforation and 35 had a previous history of perforation

Operations were performed on 4, and 10 had previous histories of operations Gastric analysis done on 192 cases gave the following results normal 52, moderate hyperchlorhydria 67, considerable hyperchlorhydria 34, hypochlorhydria 25, benign achylia gastrica 14 On discharge from hospital 207 were invalided and 197 returned to duty, many of these have presumably been invalided since

Anastomotic ulcers were found in 3 group 1 men and 2 of group 2 All were invalided from the Service

Gastric dyspepsia affected 9 in group 1 and 21 in group 2 (including 1 WRNS), a ratio of 1 to 2 3 Symptoms had lasted less than 2 years in 7, having begun in civil life in one and since entry in the rest None was suffering from hæmatemesis, melæna or perforation at the time of observation, but 9 had a history of previous hæmatemesis and 7 of previous perforation, 3 had had previous operations and 10 had a history of positive radiological findings Gastric analysis in 13 cases gave the following results normal 3, moderate hyperchlorhydria 4, hypochlorhydria 6 On discharge from hospital 26 returned to duty and 4 were invalided from the Service

Duodenal dyspepsia was found in 33 group 1 men and group 2, a ratio of 1 to 3 5 Of the 4 in whom the onset before the age of 15, one was in his 12th, one in his 13th, one his 14th and 1 in his 15th year when symptoms began 30 cases the symptoms had lasted less than 2 years, beginning in 2 of them in civil life and in 20 since entry, 8 were regular Naval personnel in whom symptoms had developed since the start of the war Previous hæmatemesis was reported in 24 and previous melæna in 12, 24 had perforated in the past, 12 had had operations, 29 had a history of positive radiological findings Gastric analysis in 63 cases gave the following results normal 14, moderate hyperchlorhydria 20, considerable hyperchlorhydria 7, hypochlorhydria 16, benign achylia gastrica 6 On leaving hospital 118 returned to duty and 30 were invalided from the Service

Nervous dyspepsia affected 16 group 1 and 60 group 2 personnel Symptoms had lasted less than 2 years in 38, of whom 1 developed them first in civil life and 34 after entry to the Service, symptoms had developed in 3 Naval personnel since the start of war thus, 37 out of the 76 cases had developed their dyspepsia since war started Gastric analysis in 35 cases showed normal acidity in 10, moderate hyperchlorhydria in 10, considerable hyperchlorhydria in 2, hypochlorhydria in 9 and achylia gastrica in 4 On discharge from hospital 72 returned to duty and 4 were invalided

Reflex dyspepsia was present in 2 group 1 and 12 group 2 personnel Symptoms had lasted less than 2 years in 2, having begun during civil life in one and since entering the Service in the other Chronic appendicitis was present in 8, chronic cholecystitis in 1 and constipation in 4, 1 had pulmonary tuberculosis Gastric analysis, in 4 cases, gave normal results in 3, the other case showed moderate hyperchlorhydria After appropriate treatment 13 cases were discharged to duty, the case of pulmonary tuberculosis was invalided

Achlorhydric dyspepsia was found only in 4 group 2 men In 1 it had begun at 16, at 26–30 in 1, at 31–35 in 1, and at 36–40 in 1 The symptoms had begun in civil life and lasted less than 2 years in 1, in 1 it had lasted for 3–5 years, and in 2 for 6–10 years There was a family history in one case and *psychological factors were present in the* one patient who was invalided Gastric analysis showed benign achylia gastrica in all 4 cases

Hyperchlorhydric dyspepsia was found in a group 2 (HO) rating aged 18, who had had heartburn, acid eructations and epigastric pain for 5 years He was discharged to duty with instructions to take alkaline powders after meals

Fat dyspepsia was also present in only one case, a WRNS of 20, who had had symptoms for 5 years She was discharged to duty

Dyspepsia after gastrectomy for peptic ulcer was seen in 3 cases, all group 2, aged 28, 32 and 37 The one case in which gastric analysis was done had benign achylia gastrica All 3 were invalided

Dyspepsia of uncertain origin was seen in 46 group 1 personnel and 175 group 2, a ratio of 1 to 3 8 Symptoms had lasted less than 2 years in 102, of whom 82 were group 2 and 20 group 1 personnel who had developed symptoms since war started Symptoms were secondary to phthisis in 1 case Gastric analysis in 91 cases gave normal results in 34, moderate hyperchlorhydria in 21, considerable hyperchlorhydria in 7, hypochlorhydria in 22 and benign achylia gastrica in 7, one of which was thought to be a case of malignant disease until gastroscopy proved the contrary In all, 188 cases were returned to duty and 33 invalided

Alcoholic gastritis was found in 17 group 2 personnel only Symptoms dated from their entry into war service in 6, 3–5 years in 5, 6–10 in 3, 11–15 in 3, and 16–20 in 1 Repeated excessive indulgence in alcohol was admitted by all the patients, and in 2 of them there was hæmatemesis after consumption of large quantities of raw spirit Gastric analysis in 6 cases gave normal results in 1, moderate hyperchlorhydria in 2, hypochlorhydria in 2 and benign achylia gastrica in 1 Gastroscopic examination, in 2 cases, revealed atrophic gastritis in one and hypertrophic gastritis in the other All returned to duty

DISCUSSION

It is established that dyspepsia in general and peptic ulceration in particular have increased considerably between 1920 and 1939 (Rivers and Ferreira 1938, Hinton 1933, Wolfert 1937) No definite reason has been assigned for this increase, but the stress and strain of modern life during the past 20 years are thought to play a notable part Under war conditions these stresses are another 2 But even with such patients success may be deceptive In cold weather chilblains deteriorate; when milder weather sets in they heal I have therefore regarded as successful only those cases which improved *during* a period of cold weather As the temperatures were low from the middle of January up to the end of February, there were at least 6 weeks of nearly uniform weather conditions in which to make observations I tried to obtain other evidence of the effect of the treatment In 3 cases only one hand was seriously affected and the other hand was nearly free from chilblains, in these, only the affected side was bandaged In 2 cases the chilblains on the treated side improved, whereas the other hand developed large chilblains where only a slight redness had been visible In the third case, the treated side did not react at once, but remained unchanged for a week, at the end of which time the untreated side was much worse than the treated Continued treatment brought definite improvement for both hands Ointments only were used on 2 cases for a week, with only very slight improvement, bandaging was then begun and complete healing followed In 2 other cases there was recurrence after the usual initial improvement, which had appeared within a week of the start of treatment *It was found, however, that the boys in question* had applied their bandages too loosely A few days after this had been put right the chilblains disappeared again

The most impressive result was that most patients reported a definite improvement in their symptoms after only a night or two Itching and tenseness had gone and pain was less Externally, no change was visible at this stage, objective signs of healing could be found only three or four days later In 3 cases the treatment was not fully successful In one success was achieved only after a fortnight, and only by bandaging the arms for 20 hours out of 24 In another all fingers of both hands were affected, during the previous winter they had ulcerated, and long treatment with ointment had been necessary This winter, hyperæmia was started as soon the first signs of chilblains became visible, in spite of this they developed, but they did not ulcerate and were not as large as they had been the year before, a response was achieved only by bandaging the arms for 20 hours out of 24, and even then healing was slow The third case showed no clear response to treatment After about a fortnight, some improvement was visible, but this may have been due to milder weather

The reason for the beneficial effect of this local venous congestion is not easily understood Lewis says that the limb which has been chronically exposed to cold reacts with vasodilatation, caused probably by the liberation of a vasodilating substance, and its temperature falls This fall of temperature suggests that the circulation in the superficial capillary blood spaces is slowed down so much that it nears complete stagnation Passive hyperæmia also leads to stagnation, but here the arterial inflow is unhindered, and only the outflow slightly impeded More blood is thus forced into the limb and moved slowly through it This movement is going on under an increased vis a tergo, and it seems reasonable to suppose that this mechanism forces blood through all potential blood spaces in the limb, including the capillary spaces dilated (and paralysed) by cold, thus reopening the circulation through them

This tentative explanation is supported by the fact that passive congestion slightly raises the temperature of a limb, indicating a good circulation If, however, the bandage is applied too firmly and the outflow restricted too much, the limb becomes cold and the congestion has no curative effect Here the greater stagnation is comparable to that produced by local cold

SUMMARY

Peripheral venous congestion by Bier's method was used as treatment for chilblains Out of 24 patients 21 were treated successfully

AN UNUSUAL MENINGOCOCCAL RELAPSE SYNDROME

A B CHRISTIE, M D ABERD, D P H

MEDICAL SUPERINTENDENT, BOROUGH SANATORIUM FOR INFECTIOUS DISEASES, SOUTHEND ON SEA

TRUE meningitic relapses after attacks of meningococcal meningitis, though uncommon, have been reported from time to time, chronic meningococcal septicæmia is a syndrome that has of late become relatively familiar The unusual feature in the first of the following two cases is the occurrence, several months after an attack of acute meningococcal meningitis, of chronic meningococcal septicæmia associated with a frankly purulent cerebrospinal fluid in a patient who showed no signs of meningitis and was in fact comparatively well and able to be up and about The second case, in which the fluid has remained abnormal for several months after clinical cure, is cited as a commentary on the possible pathogenesis of the first

CASE-HISTORIES

CASE 1 —I saw the patient, a man of 40, at his home on *Feb 7, 1941, with moderately severe meningococcal meningitis*, he had been ill two days He was mentally confused, apathetic and incontinent of urine Neck rigidity was complete, Kernig's sign was strongly positive, and there was a scanty but typical purpuric rash on chin, back and limbs On admission to the sanatorium, his CSF was turbid, meningococci were seen in the stained film He was given 2 g of sodium sulphathiazole and 20 c cm of polyvalent meningococcal antitoxin intravenously, 4 hours later, 2 g of sulphapyridine by mouth and thereafter 1 g 4 hourly to a total of 25 g Owing to short supplies it was not possible to continue sulphathiazole treatment

He responded rapidly and by the 6th day seemed normal, treatment was stopped He was allowed up on the 13th day and discharged on the 21st Two swabs of the nasopharynx were negative before his discharge, but he was not lumbar punctured because it was not then my custom to do this except for diagnostic or therapeutic reasons

Towards the beginning of July, 1941, he called at the hospital saying he felt his meningitis was returning He did not feel fit for his work as an auxiliary fireman, he had repeated attacks of coldness when all he could do was to sit in the post feeling miserable He had been rather pleased that his original illness was a serious one, so I did not regard his complaints very seriously, but I examined him carefully, in the hope of reassuring him I found nothing abnormal, no signs of meningitis, fundi were normal and blood Wassermann reaction was negative, but I did not do a lumbar puncture On July 26 I was called to his house He was in bed complaining of intense headache and shivering, his temperature was 103° F and his trunk and limbs were covered with a faint pink macular rash, Kernig's *sign* was negative and there was no trace of neck rigidity or any other abnormal sign in the central nervous system The intense headache was obviously feigned, but he was alarmed about his condition I admitted him to hospital as a probable case of chronic meningococcal septicæmia, on admission the headache vanished and the temperature fell in half an hour, blood culture was therefore not done For the next few days his temperature fluctuated though he had no physical signs On July 30 blood was taken for culture, agglutination tests

TABLE I

Date	Cell count	Protein	Chlorides	Culture
		(mg per 100 c cm)		
1941 July 31	Frank pus, polymorphs with occasional small lymphocyte	Over 200	635	Sterile
Aug 2	Turbid fluid 550 cells per c mm, polymorphs 80 %, lymphocytes 15 %, monocytes 5 %	70	560	,,
,, 14	Clear, 13 lymphocytes per c mm	60	710	,,
,, 20	3 cells per c mm	50	720	,,
Sept 15	No excess cells	40	690	,,
Nov 4	5 small lymphocytes	30	690	,,

definitely smaller exposure has had to be used for wrists, ribs in chest radiograms have appeared less dense than formerly, a large proportion of lateral views of the skull have been over-exposed and a reduced density has been especially noted in the spine and long bones The density of the soft tissues has not changed materially One of us (S. F O.) has also had many queries lately from physicians to whom the plates have been forwarded about the possible presence of osteoporosis in the spine and skull, such queries have been most unusual until recent months It would have been expected that with the ageing of tubes and equipment the exposure factors would have been increased and not, as we have found, diminished If our findings had been the result of a gradual deterioration in some quality of the film they should have been constant in every film taken This has not been the case

These observations strongly suggest that there are signs of decalcification in the bones of the general population In view of the serious implications we feel that the findings should be followed up in a properly coordinated manner Decalcification may be looked for in other directions, by comparing the time taken for fractures to heal now and 2 years ago, by examining the skeletal status of pregnant mothers and by seeing whether hospital records show an increased incidence of rickets, which is an uncommon disease in South Africa

There may be two reasons for the facts we have observed First, the cost of living has risen by about 16% since the war began, this has made foods rich in calcium (milk, cheese, eggs, green vegetables) more expensive Secondly, the population eats bread chiefly in the form of the standard loaf, which was introduced in South Africa 16 months ago and is made from a flour of 95–96% extraction Although this adds valuable nutrient properties to the diet there is unfortunately a large increase in the phytic acid content [1] If the diet of the population is poor in calcium to start with—which is very possible in the Cape Town area where much of the water is deficient in lime—the extra phytic acid will reduce the amount absorbed still further The phytic acid is the more likely cause, since decalcification has been observed not only in the poorest class of patient but also in the relatively well-to-do Further, the decalcification has been seen in rural as well as urban patients and in Europeans as well as non-Europeans To reinforce the flour with calcium carbonate would be a simple remedy

One of us (H A S) wishes to thank the Secretary for Public Health for permission to publish this paper.

PASSIVE HYPERÆMIA FOR CHILBLAINS

HERBERT HERXHEIMER, L R C P E
SCHOOL MEDICAL OFFICER AT HIGHGATE SCHOOL, WESTWARD HO

No really satisfactory treatment has been suggested for chilblains I thought it might be worth trying Bier's treatment, which consists in creating artificial hyperæmia in the limb Bier first used it for the treatment of local inflammatory processes, such as boils, carbuncles, monarthritis and the like, and it was found successful by many besides its author A constricting rubber bandage (Martin's) is applied at the level of the middle of the humerus or femur, just tightly enough to ensure mild venous congestion in the distal part of the limb, this bandage may be left in position for 22 out of 24 hours In the treatment of chilblains the bandage as a rule was used only at night, and this proved sufficient in most cases

I used a Martin's bandage 2½–3 in. wide, but any other elastic bandage, even those made without rubber, will do The colour of the limb should deepen under its influence, but it should not become colder to the touch than before, and no pins-and-needles should be felt On the other hand, the bandage should constrict the limb so firmly that coldness and pins and needles are only just avoided. A reliable sign of correct technique is that the big veins in the elbow protrude, and that the colour of the arm is deep purple, without any discomfort being present In some cases swelling of the hand is visible next morning, though it subsides in a few hours This is a sign that the bandage was put on too firmly

During the winter of 1941–42 a series of 24 people treated, 16 of whom have suffered from previous years Few of them had to be treated October, November and December, since the weather comparatively mild The majority came in J most of them schoolboys between 14 and 18, but them adults In 21 cases complete success was in 5–7 days swelling, pains, itching had disappeared, small ulcers and cracks of the skin had healed The only remaining sign was redness of the skin, sometimes associated with thickening and wrinkling of the epidermis In spite of this success, the treatment was continued for at least 6 weeks If it was interrupted after this, no recurrence was observed If, however, the treatment was interrupted after a week or a fortnight, chilblains recurred at once They disappeared again after 5–7 days of renewed bandaging No other treatment was used, except in a few cases petroleum jelly to smooth the roughness of the skin All patients were told to wear woollen or fur gloves out of doors Most of them had done so before

ILLUSTRATIVE CASE-HISTORIES

CASE 1 —A schoolboy of 18 Chilblains on hands and feet every year, always ulcerating This year slight chilblains already in July Treatment of the hands started in October, when again signs of chilblains became visible These disappeared after a week The bandaging was continued till Christmas, when it was interrupted for 4 weeks No chilblains had reappeared when bandaging was resumed by way of prophylaxis on Jan 15 In February two small chilblains developed on the hands and disappeared after a few days During the same month (the patient stayed during this period in a very cold part of the country) severe chilblains developed on both feet, which had not been treated

CASE 2 —A married woman of 60 Had *often had chilblains* in previous years In February chilblains developed rather suddenly on nearly all fingers, which showed swelling, redness, and many small cracks of the skin Bandaging brought relief after 3 days After 5 days the swelling and the cracks had disappeared, and after 7 days the fingers appeared normal No complaints since

CASE 3 —A schoolboy of 14 Chilblains 2 years before, and in previous year This winter chilblains started in December, all fingers of both hands affected In January they grew worse, two ulcers appeared on the right 4th and left 2nd fingers Treatment started on Jan 18 On Jan 25 the swellings had disappeared, the ulcers were considerably smaller and healing On Feb 5 the hands appeared normal, no complaints since

CASE 4 —A schoolboy of 15 Chilblains every winter This year they appeared early in January On Feb 13 two small ulcers on two fingers Treatment with chilblain ointment without effect Bandaging started on Feb 20 On Feb 25 ulcers healing March 2, ulcers healed, no complaints Skin still shows slight redness

CASE 5 —A schoolboy of 16 First had childblains 2 years before, feet and hands affected They started this year in mid January on both feet On Jan 20 both feet showed *chilblains, three on the right and two on the left* Swelling, itching, and pain considerable After one night of bandaging symptoms improved This improvement continued On Jan 26 all chilblains had disappeared Discontinued bandaging on Feb 4 One chilblain reappeared on Feb 10, bandaging resumed and the chilblain vanished again (Feb 18) No complaints since, though bandaging was not carried out regularly

The remaining 19 cases in the series gave similar histories and 1C of them responded equally well to the treatment

DISCUSSION

Chilblains are benign and tend to heal, if protected against cold Some patients get their chilblains through negligence, they do not wear gloves, or sufficiently wide shoes and warm stockings, every time they are exposed to cold weather, when they acquire childblains they become more careful, and this alone is often sufficient to make the chilblains heal In such cases any treatment might appear to be successful, although the healing process might not have been affected by it Better evidence is gained from those who, in spite of care, get chilblains every winter I treated 16 patients in this category, with full success in 13 and partial success in

DIFFERENT SOURCES OF PROPAGANDA

The total number of mothers covered by the inquiry, 3930, was reduced to 3860 after eliminating 70 incomplete forms. Of these mothers, 3569 (92%) had heard of the scheme. It may therefore be inferred that roughly 9 out of every 10 urban working-class mothers are now aware of the immunisation scheme so that the inadequate response cannot be due to mere ignorance of its existence.

From table I it will be seen that, of the 3569 mothers who knew of the scheme[6] 2001 (56%) had heard through the school organisations and 636 (18%) from child-welfare organisations, that is, about three-quarters had heard from these two sources. Of the remaining quarter, casual references by friends or neighbours accounted for 307 cases (9%), private doctors and other non-official medical sources for 238 (7%) and the radio for 135 (4%), taking newspapers, public posters and films together, as a category of propaganda where personal contact is lacking, these accounted for only another 172 mothers (5%). Direct circularisation by the local authorities, and nursery schools were relatively unimportant sources of knowledge of the scheme for these mothers (accounting for 2% and 0·5%).

Table I also shows the effectiveness of each source of knowledge of the scheme. For each source, mothers with children of immunisable age have been grouped according to whether all, some or none of these children had been immunised. The effectiveness of each source can be judged by the percentage of the mothers hearing from that source who had had all their children immunised; a supplementary index is the percentage who had had no children immunised, the two indices yielding similar results. *Using the first index as a basis for* comparison, the most effective sources were private doctors, child-welfare organisations, schools and direct circularisation from local authorities which resulted in about half the mothers, *in each case*, having all their children immunised. The next group in order of effectiveness comprised radio and newspapers just over a third of these mothers having had all their children immunised. Friends and neighbours public posters and films appeared to be the least effective sources of all, resulting in complete success in only a quarter to a tenth of cases. Considering all the 3497 mothers with children of immunisable age together (whatever the source of their knowledge of the scheme), 45% had had all and 40% had had none of these children immunised, the remaining 15% had had only some done.

TABLE I—SHOWING HOW FREQUENTLY PROPAGANDA FROM DIFFERENT SOURCES OF KNOWLEDGE OF SCHEME REACHED, AND HOW EFFECTIVELY IT INFLUENCED, 3569 MOTHERS

Source	Mothers (M) with one or more children of immunisable age			Mothers with no children of immunisable age	Total mothers
	Children immunised				
	All	Some	None		
	M (% *)	M	M (% *)	M	M (% †)
School (doctor, nurse or teacher)	961 (48)	387	653 (33)	0	2001 (56)

	388	769	1375	36	3043	2021	60	7596	50

Im = immunised

Taking into account both frequency and effectiveness, it may therefore be concluded that schools and welfare centres provide by far the most satisfactory media for propaganda. Personal contact by private doctors, and direct circularisation by local authorities, although among the most effective sources, reach at present only a small proportion of mothers. Radio and newspapers are roughly only two-thirds as effective as schools and child-welfare services, and they too reach only a relatively small proportion of mothers, while not only have the cinema and public posters failed to carry their message widely but the message when received has produced poor results. Clearly, the methods of direct approach (through schools, welfare centres, private doctors and circularisation) are superior to chance and haphazard sources, and it would be an improvement if direct sources could be widened from the present 80% to a 100% coverage, and the haphazard sources correspondingly reduced. It is even more important, however, that the actual effectiveness of the two predominant sources of the propaganda (schools and welfare centres) should be substantially increased.

The average figures given in table I obscure wide variations from locality to locality. These variations apply both to the proportion of mothers who had heard of the scheme from a given source, and to the effectiveness of that source. Even where the proportion of mothers who had heard of the scheme through schools was roughly the same in different localities, the effectiveness of the school propaganda differed widely, reflecting differences in the efficiency of local schemes. This may be partly due to the facts that each of the 1500 local authorities is responsible for its own publicity (though an increasing number are availing themselves of the material supplied by the Central Council for Health Education acting in conjunction with the Ministry of Health), and that the authority responsible for child welfare in a given area may not be the same as that responsible for education. There is evidently much room for increased local coördination.

Table II supplements table I by showing the effectiveness of the different sources from which mothers heard of the scheme, as indicated by the proportion of the children immunised. For this purpose, the children have been divided into three age-groups, the first for children for abortus fever, and film for malaria, all proved negative On July 31 his temperature was 100° F, lumbar puncture released thick, frankly purulent fluid A fine macular rash had again developed Treatment with sulphapyridine, 1 g 4-hourly, was begun but next day hearing that blood-culture was negative, I stopped treatment for 12 hours, and repeated the blood culture, which was again negative Treatment was resumed with sulphathiazole, on the theory that the organism might have become sulphapyridine-fast On Aug 2 the CSF was much clearer, in spite of the small dosage of sulphonamides (4 g of sulphapyridine and 4 g of sulphathiazole) Sulphathiazole was continued, 1 g 4-hourly, to a total of 32 g On Aug 14 the CSF was clear, and the patient was discharged on Aug 21 with instructions to report periodically CSF findings were as shown in table I

---

[6] We found that 9 out of every 10 mothers gave only one source from which they had heard of the scheme. The data for the minority who had heard from more than one source were analysed and as the relative frequency of sources was found to be similar the presentation of a separate set of statistics was not considered justifiable. These multiple source forms were therefore reduced to single sources by assigning each to the most important of the sources mentioned this importance being based on the distribution of the single source forms for the [illegible] in question.

CASE 2—On Nov 2, 1941, a boy of 15 was admitted with moderately severe meningococcal meningitis CSF straw-coloured, meningococci present He received in 6 days a total of 33 g of sulphapyridine and improved rapidly On Nov 14 he was ready for discharge, as far as his physical condition went, but his CSF still showed 55 cells per c mm He was accordingly given a second course of 30 g sulphapyridine On Nov 21 there were still 12 cells per c mm present and protein was 100 mg per 100 c cm, but it was impracticable to keep him longer in hospital He has reported periodically for examination particulars of his CSF are as given in table II

TABLE II

1942					
Feb 11	3	70	740	70	,,

sm lym = small lymphocytes

Pressure was increased at every lumbar puncture He has remained well except for a fortnight towards the end of January, 1942, when he suffered from recurrent headaches In view of my experience with the first case, he is being kept under observation, although it is recognised that a slow return to a normal CSF after acute meningitis is not uncommon

DISCUSSION

Although cultures of blood and CSF were both negative in the first case on the occasion of his relapse, the initial attack in February, 1941, was confirmed bacteriologically and there can be little doubt that the case was one of chronic meningococcal septicæmia, possibly originating and being fed from a focus of infection in the spinal canal Whether the CSF ever returned to normal after the original infection, and how long the patient went about with pus in his canal, is unknown, but it is likely that at least 3 weeks before his second admission and probably for longer he was suffering from repeated mild attacks of meningococcal septicæmia The most striking point clinically was the presence of a purulent CSF and the complete absence of any neurological sign From the therapeutic point of view, the danger of relying on clinical appearances in assessing cure in cases of meningococcal meningitis becomes apparent

SUMMARY

Two cases of meningococcal meningitis are described In the first several months after the initial attack chronic meningococcal septicæmia developed, associated with purulent CSF unaccompanied by neurological signs In the second case after the initial attack the CSF has remained abnormal but apart from some headache there have been no recognisable symptoms Both cases emphasise the importance of verifying apparent clinical cure by lumbar puncture The first case indicates that sulphapyridine may produce complete apparent clinical cure without sterilising the CSF

I wish to thank the medical officer of health for Southend-on-Sea for permission to publish this case, and Dr H B May of the Emergency Pathological Service for the bacteriological reports

DIPHTHERIA IMMUNISATION IN EN AND WALES

A STATISTICAL STUDY OF THE REACTIONS AND DIFFICULTIES OF MOTHERS

BY THE COMMITTEE FOR THE STUDY OF SOCIAL MEDICINE

ACCORDING to a Ministry of Health[1] estimate the proportion of children immunised in England and Wales is at least a third Since, however, the child population will not be adequately protected against diphtheria, in the official view, until at least 3 out of every 4 children are immunised, it is obvious that the response by parents to the scheme for immunisation has far from reached expectations, in spite of the varied media of propaganda and education employed In view of this, the Ministry of Health [2] has recently initiated a new campaign

The object of the present inquiry, a sample investigation carried out from September, 1941, to May, 1942, was to determine some of the major reasons for the comparatively poor response to the immunisation scheme, taking England and Wales as a whole, in order that the most efficient and economical improvements might be recommended by the committee The mother was made the focal point of the inquiry, and her reactions, objections and difficulties connected with the scheme were analysed

METHODS OF INQUIRY

To obtain a balanced sample of the total population of mothers, 25 localities were chosen so as to cover the greater part of the country, and also so as to include towns in different size-groups, as well as reception, evacuation and neutral areas [3] As the most convenient way of interviewing mothers by skilled personnel, the *lady almoner of a leading hospital in each locality* was asked to obtain the required information, and the success of the inquiry was largely due to the excellent cooperation given Each almoner was sent 100 or 200 questionnaire forms, the number depending on the size of the locality chosen, to be filled in for the first 100 or 200 mothers, having any children under 14 years old who entered her office—whether because of their own illness, or on a visit to patients, or for any other reason In this way a random sample of mothers of children under 14 attending these hospitals was obtained Although the sample is weighted in favour of urban areas and of working-class families, it is these which contain the bulk of the population at risk

The age-composition of the total number of children of these mothers was compared with that estimated for the whole of England and Wales for the year 1942[4], the differences were found to be statistically insignificant The total number of mothers covered by the sample was 3930, and the number of children under 14 years 7596 The main questions asked each mother were

1 Whether she had heard of the scheme for the immunisation of children against diphtheria

2 If she had heard, the source of her knowledge of the scheme

3 For each child under 14 years (*a*) age, (*b*) whether immunised, (*c*) age when immunised [5]

4 If not all of her children of "immunisable age" (i e, over 1 year) had been immunised, the reason for this omission

---

[1] Circular 2627, April, 1942

[2] Circular 2677, July, 1942

[3] The 25 localities and hospitals from which data were collected are as follows London, North (Royal Northern Hospital), West (Hammersmith Hospital) and West Central (University College Hospital), Manchester (Northern Hospital), Liverpool (Royal Infirmary), Leeds (General Infirmary), Sheffield (City General Hospital), Bristol (General Hospital), Newcastle (Royal Victoria Infirmary), Hull (Royal Infirmary), Cardiff (Llandough Hospital), Leicester (Royal Infirmary), Nottingham (General Hospital), Stoke on Trent (North Staffs Royal Infirmary), York (County Hospital), West Bromwich (West Bromwich and District General Hospital), Carlisle (Cumberland Infirmary), Oxford (Radcliffe Infirmary), Uxbridge (Hillingdon County Hospital), Bedford (Bedford County Hospital), Harrogate (Harrogate and District General Hospital), Tunbridge Wells (Kent and Sussex Hospital), Rochester (Hospital of St Bartholomew), Penzance (West Cornwall Hospital), Chelmsford (Chelmsford and Essex Hospital)

[4] Dr Enid Charles's "moderate assumption" in Special Memorandum No 40, of the London and Cambridge Economic Service

[5] Information under heading (*c*) has not so far been analysed

The third main group of reasons to be considered (group 3, 323 mothers) relate essentially to difficulties of administration. Nearly the whole of this group consisted of those who, while already in agreement with the desirability of immunisation appeared not to have had sufficient instructions as to how or where to have the immunisation actually done (group 3a, 301 mothers). The commonest reasons given (given by 113 of the 301 mothers) were that they were waiting until their children of preschool age were old enough to go to school and be done there, or, simply, that they did not know what to do with children under school age. Many of these mothers had heard of the scheme through the schools, but apparently did not realise that their younger children could be immunised at welfare centres: a significant number of the children were not attending these centres. The analysis thus reveals the great importance of attacking the problem of families where the older children have been immunised at school but where the pre-school children are not immunised. Of the other mothers in group 3a, 85 were waiting to hear from the school or child-welfare centre (some of these mothers had signed forms many months before), and, not having any definite instructions, they just took no steps; in some instances the delay was probably no more than is normal or reasonable. A further 14 mothers had children who were ill when their school-mates were immunised, and, on returning to school, these children found that they had "missed their turn," since their class was considered "done." Another small group (19 mothers) had difficulties associated with evacuation. Of the remaining 70 mothers, 65 "just did not know what to do," although they stated that they wanted their children to be immunised; some were not attending welfare centres. From perusal of individual forms, it appears that a large proportion of this last subgroup of mothers had heard of the scheme through casual sources, so that an improvement would be expected if the coverage by direct approach (e.g., school, welfare private doctor) be increased; it should be noted, however, that some of these mothers, unaware of facilities for free immunisation at the welfare centres, had not been to their own doctors lest a fee would be charged. Finally, only 22 of the 323 mothers in group 3 mentioned reasons directly indicating inadequacy of medical facilities (group 3b). These reasons included lack of a clinic at a reasonable distance, and shortness of supply of serum to a private doctor.

The committee is aware that the data presented are liable to errors associated with answers by the mother which involve memory and opinion though the check afforded by the written remarks of the almoners themselves on individual cases has probably reduced such errors in the present inquiry. The results should, the committee believes, form a useful complement to those previously collected in official inquiries.

RECOMMENDATIONS

On the basis of this statistical analysis, and of an examination of existing local publicity and arrangements, the committee puts forward some practical recommendations for the improvement of the immunisation scheme. It recognises that some areas are already proceeding on these or other satisfactory lines and have no need of improvement; also that an encouraging number of local authorities are responding to the Ministry of Health's recent offer of assistance in local publicity.

For Pre-school Children.—1. Efforts should be concentrated primarily on direct circularisation and personal contact by the local authority, on the child-welfare centre and the school organisation and on the private doctor. The school service and the private doctor should be particularly useful in covering pre-school children of mothers not attending the welfare centre.

2. Propaganda and definite instructions should be sent out by the local authority each month to the mothers of all children born a year previously (the "first-birthday" letter system). After a short period, the authority should send a further letter, or a representative, to mothers not responding. Arrangements should be made so that it would be possible to state that immunisation by the private doctor, as well as at the welfare centre, was free.

3. Personal propaganda by the child-welfare staff requires [illegible] be intensified.

4. To reduce the number of families with school-children immunised and pre-school children not immunised, propaganda through schools should be designed to appeal to both these age-groups. Moreover, the school immunisation service should, wherever practicable be extended to include the younger brothers and sisters of children attending school, and the school propaganda should include instructions to this effect.

5. The private practitioner should take the opportunity, when a child is brought to see him, for whatever reason, to explain the scheme and urge the mother to have immunisation done, either by himself (privately or in a special session) or at the welfare centre. His task should be made easier if, as suggested in (2) above, no charge has to be made for his services.

6. The provision in each area, of an "open access" clinic, where parents can bring their children without notice, might be considered.

7. In all propaganda it should be specifically stated that it is unsafe to wait until the child goes to school.

For School-children.—1. Efforts should be concentrated primarily on the school organisation.

2. Steps should be taken to communicate afresh, or to make personal contact, with mothers not responding to forms sent from the school, or whose child was ill or new to the school when the others were immunised. Clinics for immunisation held more often at the school would assist while children escaping these regular clinics could be immunised collectively at intervals at the welfare centres, or individually at an "open access" clinic.

General Administration.—1. To secure more efficient and more uniform schemes, there should be greater coördination of local authorities in each county or defence region, under the general supervision of the Ministry of Health; increased effectiveness of school and welfare propaganda is needed much more in some localities than in others.

2. A bulletin should be published regularly by the Ministry of Health giving descriptions and results of methods used in the more successful areas, and drawing attention to the deficiencies in backward areas and to their remedies. Mothers themselves should be drawn into local campaigns in an organised way—through housewives' committees, women's guilds, &c. In this way a local interest would be evoked for each area in achieving as high or a higher degree of immunisation than the best areas, after the manner of the "socialist emulation" movement in the Soviet Union.

3. Public posters (apart from those giving merely times and places of clinics) and films which are haphazard and relatively ineffective media, should be eliminated, and the money and effort saved should be used for improvements in the planned schemes suggested above (e.g., improved organisation of the school and child-welfare services), with their more direct approach to parents; from these, results are likely to be twice as good.

4. The radio and newspapers should continue to be used by the Ministry of Health and local authorities for special appeals and for periodic announcements about the progress of the scheme nationally or in the different areas.

General Propaganda.—The following points should be brought out in addition to those already mentioned:

1. That vaccination affords no protection whatever against diphtheria.

2. That even where a child is very healthy or does not mix with others, immunisation is still necessary.

3. That it is the duty of every parent to protect his or her child, not only for its own sake but also for the sake of other children.

4. More stress should be laid on the general harmlessness of immunisation, and it should be stated that delicate or nervous children will be considered on their merits by the doctor at the time of inoculation.

5. A special effort should be made to counter a fatalistic attitude on the part of parents, and a special appeal to the father should be included; propaganda should be arranged so that parents are induced to come to a decision very rapidly.

6. In propaganda leaflets the need for immunisation should be concisely and simply expressed, so that more space can be given to precise instructions as to the exact actions to be taken by parents to have the immunisation

of non-immunisable age (under 1 year), the second for the pre-school children (1–5 years old), and the third for the school-children (5–14 years of age) Of the 7596 children of mothers who had heard of the scheme, half had been immunised, the percentage being 36 for the pre-school and 60 for the school-children; these percentages are well below the target figure of 70–80% The higher percentage for school-children is due in part to the fact that a proportion of these children had been immunised before attending school (the proportion of school-children immunised while attending school is probably about 40–50%)

Of the 1375 pre-school children not immunised, 630 (nearly half) were the children of mothers who had heard of the scheme through the schools that their older children were attending This indicates an obvious major gap in the scope of the immunisation scheme, for as judged by individual questionnaire forms many of these mothers were not aware that their pre-school children should, and could, be immunised as well as their school-children, facilities for the immunisation at schools of younger brothers and sisters are at present uncommon The other big gap in the immunisation scheme, as it affects pre-school children, is revealed by the 360 non-immunised children (about a quarter of all the non-immunised pre-school children) whose mothers had heard of the scheme through the child-welfare organisations Since not every mother with children of preschool age attends a welfare centre, it is all the more important to succeed in immunising the children of those who do

TABLE III—MOTHERS' REASONS FOR NOT HAVING CHILDREN IMMUNISED

Reasons	Mothers (M) with one or more children of immunisable age		
	Children immunised		
	None	Some	Total
1 *Adequate reasons*—			
a Child ill, immune, or had diphtheria	146 (10)	99 (19)	215 (13)
b Intending to have child immunised	252 (18)	117 (22)	369 (19)
2 *Propaganda difficulties*—			
a Poor conception of immunisation *	215 (15)	33 (6)	248 (13)
b Apathy	371 (27)	80 (15)	451 (24)
c Prejudice (mother or father)	260 (19)	16 (3)	276 (14)
3 *Administrative difficulties*—			
a Willing, but puzzled how to act †	133 (10)	168 (32)	301 (16)
b Facilities inadequate	14 (1)	8 (2)	22 (1)
	1391 (100)	521 (100)	1912 (100)

* Or undue fears of reactions Includes confusion with vaccination and fears lest immunisation may harm or upset child

† Includes waiting for child under 5 years to go to school, waiting to hear from school, difficulties of evacuation, and general lack of information

In the 2021 school-children not immunised, the mothers of 1348 (two-thirds of the total) had heard of the scheme through schools This is the greater part of the problem for the school-children, as the percentage immunised is no higher than 63% in this case The importance of school services aiming at complete immunisation of all school-children is thus emphasised It should be noted that the relatively high degree of success (65% immunisation) among school-children whose mothers had heard of the scheme through the child-welfare organisations was due to the fact that a large part of these children had been immunised before reaching school age

It can also be seen from table II that, in the 5064 school-children, the mothers of 3625 (about 70%) had heard through the schools, whereas the mothers of only 674 (about 30%) of the 2144 pre-school children had heard from the child-welfare centres This indicates that welfare centres must increase their scope and other effective organisations must play a greater part than at present in reaching pre-school children

REASONS FOR NOT MAKING FULL USE OF THE SCHEME

Table I shows that, of the 3497 mothers with children of immunisable age, 521 (15%) had had only some of these children immunised, while 1391 (40%) had had none immunised In table III are set out the reasons given by these groups of mothers for their failure to full use of the scheme

These reasons fall into three broad groups Group consists of mothers giving adequate reasons (*a*) child or children ill, or immune, or having had or (*b*) the mother intending to have immunisation done in the near future Both these subgroups are probably somewhat inflated, (*a*) because some of the mothers investigated were visiting the lady almoner on account of a sick child, and (*b*) because some mothers undoubtedly put forward their good intentions as an excuse for warding off deeper questioning Group 1 accounts for about a third of the 1912 mothers with whom we are here concerned In group 2 (about half the total) are mothers to whom the idea of immunisation has not been "sold" strongly enough to obtain full results, these mothers have been subdivided into three grades of "resistance," although each indicates the need for more efficient propaganda In group 3 (about a sixth of the total) administrative improvements are the chief need, the mothers being already agreed on the desirability of immunisation

Group 1 requires no further consideration Of the 975 mothers in group 2 (those who gave reasons revealing *deficiencies in propaganda), about half* were apathetic, roughly a quarter were prejudiced, and a quarter had either a poor conception of the idea of immunisation or undue fears of reactions resulting from the inoculation

The 248 mothers with a poor conception of the idea of immunisation or undue fears of reactions (group 2a) are in the first stage of "resistance", once their particular confusions about the scheme are disposed of, a substantial proportion of them should be willing to have immunisation done Immunisation was often confused with vaccination against smallpox, it being thought that a vaccinated child did not need immunisation, another common difficulty was the fear lest the immunisation would harm or upset the child, in some cases when the child was believed to be nervous or delicate Other mothers stated that their children were too healthy, or that they did not mix much with other children, or just that immunisation was unnecessary The misconceptions and fears in this group of mothers may be summarised as follows —

	No
1 *Fear lest immunisation will harm or upset child*	
Heard of other children falling ill after immunisation	38
Fears swollen arms	15
Child too nervous	15
Child "too young" (though over 1 year)	10
Other causes for fear	38
Total	116 (47%)
2 *Confusion with vaccination*	52 (21%)
3 *Other reasons*	
Child too healthy, or does not mix with other children	21
Will get diphtheria in spite of immunisation	6
Immunisation unnecessary, or reason not specified	53
Total	80 (32%)

These fears and confusions are obviously real ones, which have to be specifically met in propagating the scheme

The large number of apathetic mothers (group 2b, 451 mothers) may be considered as the second stage of "resistance", these mothers usually "could not be bothered" to take any action The most difficult of the propaganda-resistant mothers (group 2c, 276 mothers) are those who appeared to have *definite prejudices* against the scheme In a proportion of these cases, the mother gave the father's prejudice as the reason, sometimes with disapproval, while this may have been an excuse in some instances it is undoubtedly a factor One of the most frequent reactions of mothers in this prejudiced group was "if he's got to get it, he'll get it" It is interesting to note that not a single mother put forward any reasons against immunisation suggesting counter-propaganda by anti-vaccinationists or anti-vivisectionists It is apparent that mothers' fears and prejudices are of quite a different character

THE LANCET

LONDON SATURDAY, NOVEMBER 28 1942

DIPHTHERIA IMMUNISATION AND THE PUBLIC

THE Minister of Health having provided the tools for the active immunisation of the child population against diphtheria is anxious that local authorities should finish the job The progress they have achieved so far is shown in the answer to Prof A V HILL s question in the House (p 655) The target is no less than the protection of between 80 and 100% of the children of preschool age in England and Wales before the end of this winter and only Birmingham and Bradford have as yet scored 50 or more although Newcastle Exeter, Barnsley Leicester, East Ham and Huddersfield are good runners-up How arduous is the course is shown by the fact that only 2 great towns (Exeter and Barnsley) have high scores for both pre-school and school-children To provide facilities is one thing, to induce the public to take advantage of them—free of charge though they are—is another Some of the unconscionable lag in bringing about the immunisation of a significant proportion of children especially those of preschool age has undoubtedly been due to the lack of effective propaganda too much faith has been placed in the prayer-wheels of poster cinema and radio too little in the personal approach When the great American cities were "selling" immunisation long ago it was soon recognised that sensible and reasoned heart-to-heart talks to parents by health visitors were far more effective than reams of paper or miles of celluloid The Committee for the Study of Social Medicine, whose report appears on page 642 have produced statistical evidence to the same effect They find that nine-tenths of urban working-class mothers are now aware of the immunisation scheme about three-quarters had heard about it through school organisations (56%) and child-welfare centres (18%) Friends and neighbours (9%), private doctors and non-official medical sources (7%) radio (4%), papers, posters and films (4%) circulars (2%) and nursery schools (0 5%) were the sources of information for the remaining quarter of the mothers interviewed. In a survey covering some of the same ground, made this summer for the Ministry of Health the findings were similar, most parents learned of the immunisation scheme through the school, the welfare centre the doctor the health visitor, friends or relatives—in other words chiefly through personal intercourse Some 25% of this sample mentioned publicity in the press, or in films wireless programmes or posters as sources of information The surveyors however believe that the exact value of publicity is difficult to gauge and that it is higher than the 25% of replies would suggest

The committee assess the effectiveness of each source of information by the percentage of mothers moved by that source to have *all* their children immunised, and relative ineffectiveness by the percentage of those who were quite unmoved to action Propaganda by private doctors, child-welfare centres, schools and direct circularisation in each case persuaded half the mothers approached to have all their children protected, radio and newspapers similarly influenced a third the other methods already enumerated swayed only from a quarter to a tenth The combined results of all sources and methods were successful (all children immunised) in 45% quite unsuccessful in 40% and partially successful (some children immunised) in 15% In the official inquiry out of 2026 families, 46 9% had had all children immunised 35 6% had had none immunised, and 17 5% had had some done When both frequency and effectiveness are considered the methods of direct approach stand out as far superior to chance and haphazard sources and the committee recommend that the actual effectiveness of the two predominant sources of propaganda (schools and welfare centres) should be substantially increased That this view is shared by the Minister of Health and the President of the Board of Education is shown in their circulars 2713 and 1610 The Minister urges that each health visitor should be made responsible for securing the immunisation of children under five in her district and if necessary should be relieved for the time being from other duties in order to carry out her house-to-house mission of persuasion The President supplements this request, and points out that the teachers are in the best position to influence parents of school-children · he has addressed a letter of special appeal and advice to the heads of elementary schools

If the campaign is to achieve its target no willing parent must be discouraged by lack of facilities The committee found that a sixth of the mothers who failed to get all their children immunised were baffled by administrative difficulties Some did not realise that plans had been made to protect preschool children some had filled in forms many months before and had heard nothing further, and in some cases a child had been ill when his class at school was immunised and so had missed his turn From the official survey it appears that no less than 10% of parents with no children protected say that they had tried to get them immunised and failed for lack of opportunity Apart from illness of the child at the time when a class was done, 38% of these parents said they had filled in consent forms and heard nothing more Thus some local authorities are evidently half-hearted in carrying out the scheme SYMONS[1] suggests that the recalcitrant parent whose child contracts diphtheria should be made to pay for his treatment whereas the local authority would bear all cost in cases arising after immunisation This would scarcely be justifiable during the present phase of scattered families A brother and sister recently returned to London from a rural county; their billets had been in villages far apart The mother had given consent for both to be immunised and believed that both had been done Actually one child had been inoculated, the name of the other was on a waiting-list, the uninoculated boy contracted in London a severe attack of diphtheria the inoculated sister in the same house escaped Which was to blame? The mother, the county authority or the war? Let us try effective propaganda and await the results of the force of example before waving the stick of penalty.

---

[1] Symons A D *Med Off* Oct 17

done, and the necessary action should require the minimum of formality

7 In written propaganda an offer should always be made of a personal talk, if desired, to clear up doubts and queries

The committee wishes to thank the lady almoners of the hospitals cooperating in this inquiry, whose enthusiastic interest made the collection of the data practicable, Captain A L Cochrane, RAMC, for an expense grant, and Mrs M Meinhardt for assistance in the analyses

---

Reviews of Books

Clinical Hematology

MAXWELL M WINTROBE, MD, PhD, associate in medicine, Johns Hopkins University, Baltimore London Henry Kimpton Pp 792 45*s*

IN this textbook a well-known American hæmatologist has presented a coherent account of a difficult subject The advances of the last ten years have been thoroughly assimilated, the work on bone-marrow and the classification and development of the erythroblasts are adequately set out, the clinical applications are woven into the descriptions of the various diseases, and when the author uses a technical term we know what he means To those who have endured the incoherence and confusion of many current books on hæmatology this consistency makes Wintrobe's book outstanding The opening account of the development of the blood, and the various changes that have been detected before birth, does not give too much space to conflicting theories of blood-cell development, Wintrobe favours a unitarian scheme modelled on Downey's, in line with present-day ideas In the section on bone-marrow there is a balanced account of the various methods of examination, and difficulties caused by the use of post-mortem material are mentioned The megaloblast question is correctly oriented, megaloblasts and normoblasts are properly illustrated

There is no special section on technique, but the various techniques are described in the sections they apply to, this innovation—aided by a good index—is justified by results In the chapter on erythrocytes, which contains a useful table of normal values at various ages, he pleads that relative values—like hæmoglobin "percentages" and the various indices—should be given up in favour of absolute values of which the most important are Hb in g per 100 c cm, mean cell volume in c μ and mean corpuscular Hb in $\gamma\gamma$ In the section on leucocytes, living cells in motion are illustrated and described, he touches on the difficulty of distinguishing the various "blasts" and reserves the name lymphocyte for cells morphologically identical with those found in the blood, adding a final warning that no character of a cell is entirely specific He remarks that the Arneth and similar counts "enshroud a relatively simple subject with an air of complexity and mysticism", and says of Hb estimation "no single laboratory procedure is more common, few are carried out less satisfactorily" He bases his classification of anæmia on red-cell morphology because it is clinically useful and his table should help to tighten up the precision of our descriptive terms, and he emphasises the necessity for accurate diagnosis before treatment The section on blood-transfusion is practical and up to date without too much detail, the inheritance of blood groups is not described—possibly because it is not "clinical" The clinical descriptions of the blood diseases are complete and satisfying The general considerations introducing the chapter on anæmia in infancy and childhood should be read by everyone proposing to describe a "new" children's anæmia A chapter on tumours and tumour-like conditions knits up several loose ends such as reticulum-cell sarcoma and splenic anæmia, and the book ends with a short but valuable section on comparative hæmatology Perhaps the chapter on leukæmias is a weak point in this good book, the composite descriptions of all forms of chronic leukæmia are not very satisfactory, especially for differential diagnosis Omission of tropical hæmatology, including malaria, is probably deliberate

This is a book full of stimulating ideas and it is readable It sets out to be "comprehensive, complete and authoritative"—and it is The illustrations are first-rate and the 2400 classified references represent cream of the literature

Recent Advances in Pathology

(4th ed) GEOFFREY HADFIELD, MD Lond., FRCP, LAWRENCE GARROD, MD Camb, FRCP London J and A Churchill Pp 346 18*s*

FOR the authors entrusted with the responsible task of keeping up to date the indispensable books in this series, it can never be easy to sift out from the mass of published work what will have a lasting value in medical science In war-time, with restrictions on printing and paper, their task is unenviable Professor Hadfield and Professor Garrod deserve special praise for having introduced into the fourth edition of this ten year old book much information and cogent criticism without increasing its length It is a pity that the chapters on the liver and the central nervous system have had to be sacrificed Some résumé of the pathology of war time industrial diseases would have been helpful today and the section on regional ileitis is briefer than could be hoped from authorities so well qualified to write But topical subjects such as crush syndrome and essential hypertension are fittingly dealt with at length Three chapters are devoted to the important subject of experimental cancer research, and new work has been incorporated, though the chapter on irradiation of tumours has been omitted The section on vitamin deficiency diseases probably testifies best to the great advances which have been made in pathology during the last four years There is a valuable critique of recent thought on infection and inflammation Altogether the book is a masterpiece of precise thinking and careful wording It can be read with profit and enjoyment by all medical men

Revelation of Childbirth

GRANTLEY DICK READ, MD Camb London William Heinemann Pp 262 21*s*

DR DICK READ takes the view that since the rectum and the bladder are hollow viscera which can contract and empty themselves painlessly the uterus being another hollow viscus should be able to do the same Arguing on this rather *Through the Looking Glass* plan he asks whether women are justified in regarding parturition as painful, and insists that they are not He judges by what he sees, since first-hand experience is not for him A man pulling a heavy load will sweat and emit grunts and groans, his face will become congested and he looks very much like a person in great pain but he is not in pain, he is labouring A woman, bearing down in the second stage of labour, presents a similar picture, she pushes and clenches her fists, grunts and growls, and to the onlookers is in agony, she may even think as much herself Thus, he finds, a most dangerous association of ideas has arisen that of childbirth and pain But her agony he believes is of the mind and not the body Proper uterine action depends largely upon a nice balance between the sympathetic and the parasympathetic nerve supply Fear is the arch-enemy of such balance, it over-stimulates the sympathetic, the circular muscle of the cervix fails to relax, the syndrome of "tense woman, tense cervix" is set up, and painful and difficult labour is the result Avoid fear, says he, and pain and difficulty will disappear, childbirth will become a beautiful and welcome experience, the crowning achievement of womanhood The first half of the book is largely concerned with the scientific justification of this theory of natural childbirth There is a stimulating chapter on the blood-supply of the uterus, and the nerve-supply is gone into thoroughly enough, most recent work being discussed The rest of the book deals with the methods by which Dr Read persuades his patients to have natural but painless labours Every woman receiving antenatal supervision is, of course, instructed about the child growing within her Throughout pregnancy quiet confidence is inculcated, and she is taught how to relax The labouring woman must never be left alone with her terrors This is all good common-sense advice He gives some records of cases, however, which suggest that on one or two occasions he has unduly risked the child's life Dr Read asks indulgence for his style, but he has no occasion to do so, the book is simple, kindly and often brilliant acute case, and detection and control of the carrier A man with colicky abdominal pain, fever and urgent diarrhœa, with later flecks of mucus, or blood and mucus, should be sent at once to a forward clearing station or to hospital and treated as a case of dysentery Microscopic examination of the fæces will decide between bacillary and amœbic dysentery, about 10% are protozoal Unfortunately a fair proportion of the mild infections are atypical and require further bacteriological examination With the ordinary culture media the dysentery bacillus can be isolated from some 90% of typical acute infections with blood and mucus, but from a much lower proportion of mild cases with mucus only Again, delay in bacteriological examination quickly reduces the proportion of positive cultures—for example in a series in the last war the organism was recovered from 68% of cases examined in the first five days of infection, from 17% in the next five days and from only 6% in the third five days[2] However, extended use of the new desoxycholate-citrate agar[3] will greatly improve bacteriological diagnosis in the atypical and late cases, for all recent reports agree about its superiority over MacConkey or similar media When the case has been clinically diagnosed and isolated, treatment with sulphaguanidine should be begun as early as possible and without waiting for bacteriological confirmation It is true, as E R **BOLAND** remarked, that cases with a mild infection may become clinically well as quickly with rest, a short course of magnesium or sodium sulphate, a bland diet and copious fluids as with sulphonamide therapy, but the consistent and often dramatic response of severe infections to sulphaguanidine demonstrates its specific curative action Other sulphonamide compounds may also be effective and **PAULLEY**[4] makes a plea for sulphapyridine, to which, however, there is the strong objection that it, like sulphathiazole and sulphadiazine, is absorbed from the bowel, and in a dehydrated patient may form crystalline deposits in the urinary tract

As important as clinical cure—and more so from the public-health aspect—is prevention of the carrier state and chronic dysentery, for it is the dysentery carrier who initiates infection in a virgin soil The prevalence of dysentery in France in 1917–18 was in part due to the drafting there of men from the East, so that, as far as possible, men should not be transferred from a unit whose dysentery is endemic to an uninfected unit It is dangerous to take the view put forward by **HONE** and others,[5] after experience in the Middle East, that examination of stools before discharge is a waste of time and that patients with no diarrhœa are unlikely to be dysentery carriers The new selective culture medium has shown that the convalescent dysentery carrier is much commoner than was formerly thought, and **FAIRLEY** found by sigmoidoscopic examination that many of such carriers still had unhealed purulent ulcers in the intestinal mucosa This convalescent carrier state **ROBERT CRUICKSHANK** pointed out can be prevented by early treatment of the clinical case with sulphaguanidine, or, where the patient has already become a carrier, can usually be bacteriologically cured by the drug if the infection is due to one of the Flexner group of organisms[6] The Sonne carrier is less amenable to chemotherapy, although sulphasuxidine is proving more effective than sulphaguanidine Thus, there is more than one good reason for treating every case of bacillary dysentery with the new intestinal antiseptics, which it is hoped will now be more plentiful In war, even more than in peace, the medical officer must be epidemiologist as well as physician, and one of his objectives must be to return a non-infectious as well as a fit man to his unit with the least possible delay

Annotations

THE HUNGRY COUNTRIES

THE Swedish committee for the relief of Belgian children writes from Stockholm that it is no longer possible to get official figures of the death-rate of children there Conditions are appalling far more serious than they were a year ago In Greece things are even worse The Archbishop of Canterbury and the Cardinal Archbishop of Westminster have in person asked the Foreign Secretary to present to the Government a request from the Famine Relief Committee, of which Miss E M Pye is hon secretary, for permission to send dried milk and vitamins to the children in Greece and Belgium They ask for navicerts, allowing the committee to send the minimum of these commodities necessary to maintain the lives of children under the age of 16, of expectant and nursing mothers and invalids in Greece and Belgium during the coming winter Dried milk and vitamins represent the maximum of nourishment for the smallest amount of shipping space Distribution can be controlled because the bulk is small, and the materials can be surely and conveniently handled by the welfare and feeding centres run by the Swedish and Swiss Red Cross Societies The quantities have been carefully worked out by the Famine Relief technical advisory committee Greece and Belgium are suffering most at present, but need is urgent and growing in France, Poland and Norway Similar calculations could be made on behalf of the children there It is true that large scale plans are already being made for feeding, clothing and rehabilitation of the occupied countries when their servitude ends Mr H H Lehman, retiring governor of New York, has just been appointed to direct them, and we may be sure that everything possible will then be done But that will be too late for hosts of those who are starving now Immediate prophylaxis will have the backing of all who twenty years ago saw the irreversible results of starvation during the period of growth English children might have been the hungry ones this winter if chance had taken a slightly different turn We earnestly hope that the Government will see their way to grant those navicerts

LABORATORY TECHNICIANS OF THE FUTURE

IN the last few years the laboratory technician has come to occupy a key position in the organisation of medicine No medical laboratory fulfils its function unless its activities are closely integrated with clinical work, and though this integration must depend upon medical personnel the technical staff supplies much of the motive force of the laboratory, these two rôles are well recognised and in laboratories are to be found some of the happiest examples of interdependence between fellow workers within the same mystery. The place of the pathologist is well defined and his recruitment follows recognised lines Not so with the technician, his recruitment has been and still is a somewhat haphazard affair He enters as a lab boy chosen perhaps

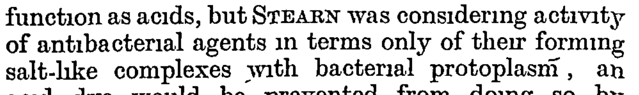
BASICITY AND DRUG ACTION

STUDIES of the ways in which antiseptic activity varies with chemical structure and physical properties have in the past achieved notable practical results—for example, the work done on the relations between narcotic action and lipoid solubility, and between the action of chaulmoograte analogues on acid-fast organisms and their activity in depressing the surface tension of water Such correlations have since the time of CRUM BROWN and FRASER of Edinburgh inspired those who were trying to establish a material basis for drug action ALBERT and collaborators[1] at the University of Sydney have investigated the basicity of aminoacridines and correlated this property with their antibacterial activity, their recent findings are set out on another page This work is related to that of the STEARNS,[2] who brought forward evidence that many triphenylmethane dyestuffs which are antiseptic act as cations, their activities being in the order of their estimated strengths as bases and increasing with increasing pH of the medium in which they are tested They therefore suggested that these dyestuffs act by combining with acid groups in the organism inhibited, and ALBERT envisages a similar mechanism in the case of aminoacridines These compounds he finds particularly suited to exact measurement of their strengths as bases by potentiometric titration and his correlations thus have greater significance than those of STEARN

STEARN himself maintained that there is probably no fundamental difference between the action of antiseptics and of other antibacterial agents, the activities of mercuric salts or of crystal violet could, under suitable conditions, be reversed and affected organisms be again rendered viable It is therefore notable that the triphenylmethane antiseptics and aminoacridines have in common with the sulphonamides an increased activity with increase in pH of the medium in which they act The sulphonamides[3] are thought to act by virtue of the similarity of their ions



$\mathrm{R-S(=O)(=NH)-O^{-}}$ to that of p-aminobenzoate, $\mathrm{R-C(=O)-O^{-}}$

Thus any influence, such as alkalinity, which increases the concentration of anions in their solutions increases their activity[4] It is inconsistent with STEARN's ideas, as they were then expressed, that increasing alkalinity should increase the activities both of substances which function as bases and those which function as acids, but STEARN was considering activity of antibacterial agents in terms only of their forming salt-like complexes with bacterial protoplasm, an acid dye would be prevented from doing so by increased alkalinity, which would keep it in solution as its anion, such is, however, the functioning form in the case of the sulphonamides SCHMELKES and others point out the clinical corollary to their findings that it is advisable to keep the pH of infected loci as high as possible during sulphonamide treatment, at pH 9 there is comparatively little difference between the antibacterial effectiveness of sulphanilamide and of sulphathiazole

The investigations which ALBERT reviews show that drug action is subject to physical and chemical laws, but they give no reason for the application of a particular rule to a particular case why should a quaternary nitrogen atom be important in some instances, and surface tension, molecular weight or basicity in others? Again, why are such correlations usually valid only in limited groups of compounds of similar structure? While the parallelism between basicity and antiseptic action is complete in the aminoacridines investigated, it will not extend far to other amines The only answer which can be given in most cases is that the different types of agents act at different receptor sites whose characters are such that they interact with molecules of given physical or chemical types In the system investigated by SCHMELKES the nature of this interaction can be stated in greater detail, for the sulphonamides act *by inhibiting enzymes whose normal substrate is p-aminobenzoate* Correlation of their activity with their approach to the physical and chemical (but not physiological) properties of *p*-aminobenzoate is thus explicable, and it is presumably in such biochemical terms that the action of other antibacterial agents will ultimately be explained

CONTROL OF DYSENTERY

BACILLARY dysentery can be one of the major scourges of war In the first world war, when enteric fever was largely controlled by prophylactic vaccination, dysentery was the prevalent intestinal infection, first in the Eastern theatres and later in France, and was responsible for a great wastage of manpower For example, the average period of invalidity in a selected group of cases in 1915 was 68 1 days and in 1917–18, 141 2 days[1] In the present war, despite the number of troops in the Middle East, dysentery has not so far assumed major proportions, and in Egypt, according to N HAMILTON FAIRLEY speaking at a meeting of the Royal Society of Tropical Medicine on Nov 4, there have been no large-scale epidemics like those of the last war Moreover, the infection has been mostly mild because of improvements in hygiene and feeding, the rarity of intercurrent debilitating diseases, and the small proportion of Shiga infections (around 10% as against 50–60% in the last war) The greater use of mechanised transport may also have reduced breeding facilities for the fly, though from all accounts this carrier of disease is still very prevalent in Egypt

For the control of dysentery in the Army, FAIRLEY insisted on the great value of prophylaxis by a high standard of sanitation, which includes such procedures as the use of deep trench latrines sprinkled with borax or other disinfectant, the covering of excrement of troops on the move, the education of military personnel by the medical officers through talks, posters and the like, close supervision of the kitchen and kitchen staff (kitchens with a dark interior and screens of fish-net were found to be good fly-deterrents), and the provision of Moslem latrines for the native labour In dealing with the actual infection, the important points are early diagnosis, isolation and treatment of and most of them have wives and children to keep If their hospital service as leading sick-berth attendants has been adequate, the GNC allow them to sit for the state preliminary and final examinations without delay, but naturally few of them do so The central council would like to see them admitted to the register without further examination, but this would entail a change of legislation Since the act will have to be reviewed if, on the advice of the Horder committee,[2] assistant nurses are to be trained and enrolled, the opportunity might be taken to meet the needs of these men The GNC might feel that their place was on the roll of assistant nurses rather than on the state register In that case they would at least be in a position to earn a reasonable salary, but they would still be ineligible for the higher nursing posts Alternatively—at least during peace time—the Navy might arrange for these men to take the state examinations during their training, instead of preparing them for exclusively Naval examinations which have no general market value Since those who specialise in massage are able to take the qualifications of the Chartered Society of Masseurs, similar opportunities could presumably be arranged for those taking nursing to sit for the state examination In peace-time the RAF arranges for men who have taken the Service trade examination in nursing to sit for the state exam if they wish.

TOXICITY OF MERCURIAL DIURETICS

James Mackenzie was always pleased to hear that digitalis had produced nausea and vomiting because then he felt sure he was dealing with an active preparation of the drug This story may be apocryphal, but there is a deal of sense in it A really potent drug will always produce toxic symptoms if given in excess, it is only the placebos, which constitute the greater part of the doctor's therapeutic armamentarium, that can be taken in almost unlimited amounts over indefinite periods without producing adverse effects The organic mercurial diuretics have lately come into wide use and it is inevitable that their toxic manifestations should receive undue attention for a while It appears from a symposium in the *Journal of the American Medical Association* for July 25 that the comparatively few fatalities reported have been due to four main causes (*a*) the use of these drugs in unsuitable cases (e g., in patients with renal disease)[3], (*b*) their continued use when they have already produced toxic effects (thus in one patient 18 out of 19 consecutive injections produced attacks of severe dyspnœa and orthopnœa lasting 2–3 minutes and the 20th injection was followed within 3 minutes by permanent cardiac asystole)[4], (*c*) the use of excessive doses, for example, 4 c cm intravenously[3], (*d*) the use of these drugs in patients likely to die at any moment so that there is no evidence that death was due to the diuretic DeGraff and Nadler[5] point out that the toxic effects may be due either to the associated diuresis or directly to the drug itself Excessive diuresis may produce disturbed electrolyte balance and the mobilisation of digitalis stored in œdema fluid—effects which need cause little concern provided the diuresis is not beyond all bounds, and provided the patient has not been heavily digitalised at the time when the diuretic is given This does not however contra-indicate the combined use of digitalis and an organic mercurial diuretic in the treatment of cardiac œdema—a combination which, as Thomson[6] has pointed out, successfully gets rid of œdema, improves the general condition of the patient and hastens the recovery of the myocardium Direct toxic effects of the mercurial diuretics are principally on the kidneys, producing tubular degeneration, and on the gastro intestinal tract, producing stomatitis and colitis, chills and fever have also been noted, and more rarely a state resembling shock A proportion of the toxic effects, including the occasional sudden deaths that have been recorded, may be due to the development of hypersensitiveness to the drug This might explain some of the reactions which occur in patients who have tolerated one or more doses satisfactorily and then suddenly react violently to a subsequent dose Evidence on this point, however, is lacking Fox and his colleagues[7] have reported a carefully investigated case in which the patient reacted strongly even to such small doses as 0 1 c cm of one organic mercurial diuretic, and here there was no hypersensitiveness to mercury bichloride, suggesting that the reaction was not due to the liberation of a more toxic ionised mercury, neither was there any reaction to a cutaneous scratch test for sensitiveness to the diuretic This case also illustrates the important practical point that patients who react unpleasantly to one member of this group may tolerate another one quite satisfactorily This group of drugs has become much less toxic since the organic mercurial salt was combined with theophylline The toxicity of 'Novasurol' is now merely of historical interest, since it has long been given up DeGraff and Lehman[8] have shown that when lethal doses of the mercurial diuretics are given rapidly to cats death is due to action on the heart, the drugs interfere with intraventricular conductivity and eventually cause ventricular fibrillation They found that sudden deaths could not be prevented by slow injection, and dilution of the drug did little to reduce toxicity, preliminary treatment with oral ammonium chloride, phenobarbital, or intravenous Nativelle's digitalin had no effect on the lethal dose But if they could discover only 26 deaths reported by clinicians, including the most carefree, during the last 16 years as being due to these diuretics, their risk must indeed be low

KEEP THE HOME FIRES BURNING LOW

SOME three million homes on the United States Atlantic Seaboard and Middle West are to have the fuel oil they use in their heating installations curtailed by about a third this winter With a view to lessening the resultant hardships a committee of medical, public health and ventilating experts have studied and reported on the health aspects of the rationing plan[9] Opinions varied on the minimum temperatures necessary for health and efficiency, but the majority opinion fixed 65° F for private and apartment houses, schools, shops and offices, 65–70° F for hospital wards and 80° F for operating theatres—rather higher than the comfort standards accepted in Britain Heating of bedrooms is considered unnecessary, except for infants, the aged and invalids, and the family is advised to take turns for dressing and undressing in the bathroom Like Sir Leonard Hill,[10] the committee urged the need for using extra clothing to save fuel—"Wear a sweater and help win the war" is their slogan Hill advocated colder factories and offices, outdoor clothes and warm underwear, and if necessary an overcoat being worn in the factory, only enough heat being provided to keep the hands warm enough for skilled work Sedentary workers, says Hill, can keep warm at their desks, as they do (or did !) when travelling in a car, by wearing an overcoat and having a rug round the knees and a hot-water bottle at the feet So protected, he maintains, with no fire and the window open, work can be done with improvement in health, it is far better for health to because someone thinks he looks promising, and his subsequent training and final destiny largely depend on luck Time and chance, as the Preacher remarks, happen to all men, but a planned society refuses to accept them blindly The medical laboratories of this country can testify that the old fortuitous methods did not work too badly, but that is not to say they cannot be improved

The efficiency of the present technical staffs of the medical laboratories of this country is largely due to the efforts of the Pathological and Bacteriological Laboratory Assistants Association Lately a committee of the Association of Scientific Workers has been considering the training and future status of these essential workers in the medical field The PBLAA has applied for registration, under the name of the Institute of Medical Laboratory Technology, and is asking for statutory powers to organise and direct the training, examination and qualification of its members It has been suggested that a commission should be set up to consider the question of training, on which all interested bodies, including the IMLT (when established), the Pathological Society, the Association of Clinical Pathologists and the ASW should all be represented In the past the young technician has always been expected to spend a good part of his time as bottle-washer His training has depended upon opportunity, the goodwill of the senior technician and his own capacity to take advantage of whatever chances offered Sometimes one, sometimes another, and sometimes all three have been lacking Any scheme for the education of technicians should ensure that entrants have the capacity and desire to learn, and that they have the opportunity to use them Not all lads who may fancy laboratory work prove to be suited to it, and aptitude can only be determined by experiment, all entrants should serve a probationary period before undertaking the career of technician Bottle-washing as a preliminary test of aptitude is not to be despised—the lad whose presence is signalised by the crash of shattered glass-ware is obviously better directed elsewhere—but it should not be allowed to engulf so much of the accepted student's time that he has no opportunity to learn more skilled work The existing state of affairs in which the most recent entrant to the laboratory may find himself stuck indefinitely on the lowest rung of the ladder must be remedied

The ASW committee has made some suggestion about the age and stage of education at which the technology probationer should be accepted but this as yet seems scarcely necessary The school-leaving age must set the lower limit, in all towns possessing a laboratory fitted to take probationers there will almost certainly be a technical school at which they may attend evening classes in the needful subjects The probationary period should be limited, and at the end of it the student should have the opportunity of entering at once upon his training proper Not all medical laboratories offer teaching facilities appropriate to such training It can only properly be pursued in those offering considerable facilities for teaching, these are few and attached for the most part to universities, but it may be that with increase of laboratories as a part of a national hospital service others not necessarily attached to universities may be fitted to take on this work The student will have to learn the basic principles of chemistry, physics and biology, to the standard acquired by medical students in their preclinical years Some systematic instruction is essential, but it should not become a burden, though the laboratory technician must be sufficiently acquainted with the essentials of the sciences with which he deals to be able to understand what he really is doing, his work is primarily practical and he needs practical instruction in all the routine laboratory methods applied to general medicine The committee feel that an appropriate course could not be taken in less than two years by a student who had passed lation, but this may be setting the academic high, and might exclude practical technicians in of those who were merely good at their books examination conducted by the court of the IMLT qualify the student to take up a junior post in a la tory, 2 or 3 years of experience as a junior entitle him to attempt to sit for his final examination as a master of his craft The period in the training school might be too expensive for some likely candidates, but this difficulty could be overcome by a scheme of scholarships, bursaries or repayable grants in aid

To devise and put into effect a scheme of training for the technician is not a simple matter, but the provision of an adequate supply of properly trained medical laboratory technicians has national importance and the efforts of the ASW committee will command the fullest sympathy of those interested in the development of the national medical service

THE SAILOR NURSE

MEN who have trained for the sick-berth staff of the Royal Navy and retire after at least twenty years' service are at a disadvantage when it comes to finding a job in civil life Surgeon Rear-Admiral J Falconer Hall asked on their behalf in our columns [1] that they should be given a definite status in any new nursing act which might come into force He wrote as secretary of the Central Council of the Royal Naval Sick Berth Associations, a voluntary body formed by Naval medical officers to help these men to find work At the beginning of their training the men are entered on probation, only after a stiff medical and educational test During their first year they have a course of training and pass an examination for the rating of sick-berth attendant, if they fail they are discharged from training Later they take practical and written examinations for the ratings of leading sick-berth attendant and sick-berth petty officer The rating of petty officer is equivalent to that of a sergeant in the Army and cannot usually be obtained after less than 7 years' service The central council considers that these qualifications in no way fall short of those required for the certificate of state registration The men join for 12 years and may leave after serving that time, but most of them go on to complete the 22 years which qualifies them for a pension, and are then usually over 40 Nearly all of them hold the good conduct medal, which means that for 12 consecutive years they have had a "very good" report on their service certificate Their service is spent in Royal Naval hospitals at home and abroad and in ships all over the world, and they look after surgical, medical and mental cases They get experience with nearly every type of acute case and during training are instructed in the principles and practice of general nursing, first-aid, invalid cookery, disinfection, stretcher drill, and medical accounts and store-keeping They undertake the care of instruments and learn elementary dispensing Some specialise as masseurs, and are registered under the Chartered Society, others become radiographic, laboratory or theatre assistants The numbers adversely affected are not large about 50 leading sick-berth ratings are discharged annually and of these perhaps 30 will want to continue nursing Lacking the state qualification, however, they are debarred from all the better paid posts as male nurses in civil life, and cannot participate in the superannuation schemes of local authorities The General Nursing Council are powerless to help them because their hands are tied by the Nurses Registration Act State registration is the only recognised qualification for nurses in Great Britain, and the only portal of entry to it is through the state examination Men between 40 and 50, however, who have been practising as skilled nurses for many years, are not anxious to take more examinations,

Special Articles

GENERAL MEDICAL COUNCIL

PRESIDENTIAL ADDRESS

OPENING on Tuesday the 156th session Mr H L EASON referred to the many changes in membership since the last meeting of the council Sir Norman Walker, who died on Nov 7, had been a member for 34 years of amazing activity His knowledge of the history of the council and of its minutes was unique There was no problem that he could not simplify by his familiarity with precedent and tradition, and he used his wisdom and judgment unceasingly for the benefit and the assistance of the council Prof David Waterston, who died on Sept 4, was remembered for his unfailing kindliness and modesty, his industry and his impressive knowledge of standing orders Prof Edw Fawcett, who died on Sept. 22, was a member of the council 1925–35, his expert knowledge was of the greatest value as visitor of examinations in biology Dr Leonard Kidd who died on Oct 2, had been the father of the council, with a distinguished record of public services in Ireland The retirement of Mr Harold Collinson to become inspector of qualifying examinations in surgery had brought Prof Matthew Stewart to represent the University of Leeds, his experience both in the applied sciences and in education will be of assistance to the council in these times Dr T S Hele was succeeded as representative of Cambridge University by Prof Roy Dean, himself no stranger to the council, for he had sat for Manchester 1919–22 Dr Kidd's place was taken by Dr Frank Kane professor of physiology in University College, Cork, and Prof W H Gilmour's by Dr Eric Wilfred Fish LDS

The President had little to say in advance about the business of the session The education and examination committees would jointly present a report on evidence prepared for the Board of Education's committee on curriculum and examinations in schools, and for the inter-departmental committee on medical schools In accordance with the council's decision in June an inspection had begun of qualifying examinations which had been accelerated as a matter of emergency The provisional appointment of inspectors by the executive committee was to be ratified At a suitable moment would be discussed the recommendations of the executive committee as to the arrangement of the sittings to the best advantage both of the public and of members

He has been asked said the President, to draw attention to the case of an alien, apparently unqualified, who by false pretences obtained a recommendation and testimonials from doctors for professional purposes Doctors should not accept unverified statements by other persons that they are qualified or registered, and aliens who are registered in the Medical Register, whether temporarily or otherwise should be in possession not only of a certificate of registration issued by the GMC (which is not evidence of identity), but of a police registration certificate endorsed with the conditions under which they are entitled to take up professional work, or accompanied by a Home Office letter setting out those conditions

The penal business before the council, he concluded, is likely to be difficult and possibly protracted

A SURGICAL QUORUM

WITH gratified astonishment SIR ALFRED WEBB-JOHNSON welcomed not only a quorum but a handsome surplus at the annual meeting on Nov 19 of the Royal College of Surgeons It showed, he said, a quickening of interest among fellows and members in the way their affairs were conducted by the council Time was when the annual meeting was a battleground for members seeking representation on the council, in these peaceful war-time days, with no immediate hope of changing charters, they could discuss the year's work in amity The Interdepartmental Committee now inquiring into medical schools and research would be likely, he felt, to cover a wide field, making in its stride recommendations, affecting the college, about examinations for diplomas and about the training of consultants The college is, he said, taking part in the work of the Medical Planning Commission; he mentioned the names of Mr John Hunter of King's and Mr Wilfrid Adams of Bristol in this connexion During the year some of the younger fellows had protested that they had not had full information when voting for members of council, this objection had received sympathetic consideration and the voting regulations were being modified to meet it He referred to the postponement (see *Lancet*, Nov 7, p 552) of the primary examination to the postgraduate years and the inclusion in it of pathology Entrance to the final fellowship had hitherto been governed by rules which operated somewhat unfavourably against overseas candidates Most of them cannot be admitted to the final examination, until four years after qualification and this causes some hardship by delaying their return to their own countries The council feels, he said, that this needs amending, and also that no candidate should be admitted to the final fellowship examination without a longer period of postgraduate training than is required at present Application had therefore been made for alteration in the by-laws so that conditions of admission can be changed as circumstances required He reminded the meeting that the onus of restoring the Hunterian Museum lay on practising surgeons, whom he asked to collect specimens During the year the Royal Eye Hospital had approached the college, suggesting that a research chair in ophthalmology should be founded The college had agreed, and would provide laboratory facilities, the hospital guaranteeing the salary and the professor being one of the surgeons to the hospital The appointment would be for five years in the first instance He mentioned the generous and timely gift by the American College of Surgeons of £2000 towards the restoration of the college The three Royal Colleges are working together through a standing joint committee, and a project might be put forward, he said, for them to unite in one building After all, there was nothing revolutionary in this concept, for medicine, surgery and obstetrics were all part of one whole; and many of the best physicians he knew were surgeons If in the forthcoming changes in medical organisation the consultant was to be paid from public funds, he must have accredited qualifications, and the central academic body deciding those qualifications should be formed by the three colleges

Mr R M HANDFIELD-JONES remarked that the lack of interest shown in the affairs of the college was a danger at this time when many bodies were planning for the future of medicine He thought, however, that the apathy was understandable if the administration of the college was compared with that of the Royal College of Physicians There all fellows were at liberty to attend the meetings of comitia and to give their views Though the surgeons charter would not permit of comparable meetings, he thought it would strengthen the hand of the council if informal open meetings were held at which they could learn the opinions and feelings of fellows Should the Interdepartmental Committee try to force unacceptable proposals on the college it would be of use to the council, in opposing these, to know that they had the fellows behind them He welcomed the idea of close coöperation between the colleges, but if they decided to share a building two of them would have to move Moreover, while it was easy to work together it was not always so easy to live together In any case he hoped the council was not contemplating giving up their historic site His proposal that the annual report should be adopted was seconded by Mr ERIC CROOK Mr. D H PATEY suggested that in the restored museum the emphasis should be on quality rather than—as of old—on quantity

The PRESIDENT in reply said that it would be hardly practicable to have meetings analogous to those of the comitia, since the fellows of the college numbered some 2700, as compared with some 700 fellows of the Royal College of Physicians In the council, the affection for the present site of the college, he said, was probably even stronger than among the rest of the fellows; in any case there was £100,000 promised in war damage which could not be transferred if the college moved to another site

---

Messrs BRITISH DRUG HOUSES have now prepared a leaflet on the use of S methylisothiourea, the blood pressure raising drug investigated by Smirk (*Lancet*, Sept 12, 1942, p 301) It is issued in 2 c cm. ampoules containing a 10% solution of the sulphate for intravenous injection.

wear more clothes than to cut down ventilation On the other hand, since it is the air entangled in the mesh and between the layers of our clothes which prevents heat loss, we must prevent draughts or winds blowing this air away, if necessary by wearing waterproof (and therefore windproof) overclothes The American rationing authority will allow households with children under 4 years (and hence nursing mothers) supplementary fuel to provide a living-room temperature of 70° F , the advisory committee say that older children need a cooler and not a warmer environment than adults They would also allow an extra ration to households with one or more members over 65 (" some people are old at 55, others young at 70 "), leaving the doctor to decide the needs of invalids, but so far no extra allowance has been made for the aged A medical certificate for extra fuel must specify the approximate temperatures required which will puzzle the conscientious certifier The ration is based on past consumption and on the thermal efficiency of the house as indicated by a heat-loss floor-area formula But the American rationee has a pull over us, for if he converts his fuel-oil burner to coal he can be assured of all the heat he wants

FIBROSITIS, ORGANIC AND INORGANIC

THE condition referred to as fibrositis is still one of vague pathological and clinical definition , some sceptics deny its existence altogether, so that it is not surprising that the diagnosis has fallen into disrepute Ellman and others[1] have made a careful clinical and psychological study of 50 patients to whom this label had been loosely applied and found in only 54% definite physical findings —tender points giving rise to referred pain which could be abolished by procaine injection—significant focal sepsis, sacro-iliac strain, &c The remaining 46% showed no physical signs, and while the psychological analysis of the whole series revealed neurotic disorders in 70%, these were much more in evidence in the minor group without objective features Most of these suffered from hysteria of the histrionic, plaintive or resentful type, and a few from anxiety or depressive states , their complaints were of vague shifting pains unlike the localised symptoms of those with organic disease, and, in general, the degree of psychological upset was inversely proportional to the physical findings It was particularly noteworthy that even severe prolonged organic disease did not tend to lead to psychological abnormalities , neither seemed to be related to the other as an ætiological factor The mechanism by which a psychoneurosis gives rise to pain of this kind is not clear , Ellman and his colleagues suggest that repressed aggressiveness, a causal element in hysterical and anxiety states, results in muscular tension which is interpreted by the individual as pain and by the doctor as fibrositis This explanation may not appeal to the orthopædic surgeon, but it may persuade him to restrain his own aggressiveness towards these very trying patients and refer them gently to his psychiatric colleague

NATIONAL PHYSICAL LABORATORY TO HELP

SOME workers in X-ray departments still fear the possible effect on their health of prolonged exposure to radiation These fears, coming to the knowledge of the Minister of Health, have not been brushed aside by him as though they had no foundation in fact (circ 2718, 16 xi 42) He takes the frank attitude that " in a well-run X-ray department where proper precautions are taken, the risk to health is small " However small, it is not negligible, for we do not yet know what are the safe limits to which a man or woman can be exposed to X rays without suffering some harm A good idea of the dose taken during a working day can be obtained by carrying in the breast pocket a dental film which is and the tint compared with a colour series corresp to known doses of radiation This convenient reasonably accurate method has been in use at some hospitals over a period of years But there are no doubt other hospitals where such tests could not readily be done, and arrangements have been made with the National Physical Laboratory to organise a service for testing the amount of radiation received by X ray workers and to advise what further action, if any, should be taken in the light of the tests Should the film test show a dose approaching (or exceeding) the tolerance value laid down by the British X-Ray and Radium Protection Committee, the hospital authority should have the X-ray equipment tested by ionisation methods, and the worker's technique investigated Authorities making use of such services should note

(1) Application for films (one film per person) should be made to the Director, National Physical Laboratory, Teddington, Msx

(2) After exposure the films should be returned to the laboratory with a remittance of 2*s* per film to cover cost of report

(3) Should this report be unsatisfactory the laboratory will arrange for inspection of apparatus and technique, at a fee, for a department of normal size, of about £5

Where use is made of these services by an EMS hospital, the fee may be included in the periodical statement of running costs

DETERMINATION OF PLASMA PROTEINS

THE plasma proteins have come in for a lot of study in the last few years Whipple[1] and his colleagues in Rochester, N Y , have worked on their formation and metabolism, and lately Beattie and Collard[2] have brought forward evidence supporting their view that besides the protein circulating in the plasma there may be considerable stores in liver and other body cells and that exchanges between the circulating plasma and storage organs are relatively free Apart from such inquiries, determination of serum proteins has acquired a value in the assessment of nutritional status and in the treatment of disease There are, broadly speaking, two principles by which these determinations can be carried out The old-established chemical method consists in separating the proteins by suitable reagents and determining the total nitrogen in them This is by far the most reliable method and enables the albumin and globulin to be recorded separately , moreover, the latest modifications require very small quantities of material In late years, physical methods have been introduced , the specific gravity of serum depends mainly on the amount of protein in it, so that the percentage of proteins can be calculated from the specific gravity , in the best known method of the kind the time taken for a drop of serum to fall through a known height of some immiscible liquid is measured Though convenient and accurate enough for some purposes, these physical methods do not differentiate albumin and globulin Taylor and Gibbons[3] have lately recorded a rapid physical method, depending on whether a drop of serum floats or sinks in appropriate mixtures of xylene and bromobenzene The test, though crude, could be used at the bedside , and they suggest that it might be useful under Service conditions All methods, this one included, require the separation of the serum or plasma from the corpuscles as a preliminary step , and once this has been done there seems little reason why one of the more accurate and equally rapid physical methods should not be used in any hospital where laboratory facilities are available

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

THE discussion of amendments to the Address has been roceeding now for two weeks and will probably continue or another The amendments range over the control of unt, the opening of cinemas on Sunday, equal compensation for men and women for war injuries, the naval ar service, price control, Welsh affairs, the Atlantic harter, India and the Colonies, children's allowances, ocial inequalities, workmen's compensation and civil viation The chief amendment on health questions ut forward in the name of Prof A V Hill, FRS, most f the medical members of Parliament and many other nembers of all parties, regrets "that further provision s not made for reducing the delay in applying the stablished results of scientific and medical knowledge," nd mentions specifically venereal disease, tuberculosis nd diphtheria, together with the problems of factory ygiene and the health and nutrition of young people Unfortunately, despite the unusually long time available for discussion, the Speaker has decided not to select this mendment as one to be called, which would make a debate certain, and the whips have decided not to ask time to be allocated This is one of the penalties of independence, for Prof Hill is an "independent" Conservative, and an all-party motion is less interesting than one challenging a party conflict The new venereal disease regulations will however be the subject of debate, as Dr Summerskill, Mrs Hardie and Mr Driberg are moving a prayer that they be annulled Dr Summerskill thinks the regulations are not drastic enough and Mrs Hardie does not like them as they are

The last day of the debate last week was a patchy affair, two members talking about pensions appeal tribunals, Mr Clement Davies of the urgency of planning for the post-war world and the desperate need of not betraying the fighting men after this war if we are to avoid revolution, Mr Gallagher on the Second Front, other members on miscellaneous topics It was all wound up by Mr Ernest Brown, Minister of Health, dealing particularly with housing As the member for Evesham might say in a mood of under-statement, "not very satisfactory" But the day went like that, and those wanting to discuss Prof Hill's amendment were not called Frustration is a malady quite well known to MPs, especially to independent-minded MPs Debates of this kind put members' views on record in *Hansard*—and no doubt in the press in their own constituencies—but they do not achieve debating results although they make the opportunity for ministerial statements The previous day's debate was more useful because there was a clash of feeling and opinion You do not get light in the House as a rule unless you also engender heat The heat on this day was engendered by a further refusal of the Government to set up pensions appeal tribunals on the ground that the thirty or so doctors required could not be found Although Sir Stafford Cripps said this it was difficult to believe it; one member said Sir Stafford had an untrue brief provided for him and others made the scoffing noises known in parliamentary records as "interruptions" It is widely felt in all parties that the refusal to set up tribunals is a mistake There is a shortage of doctors, of course, but men are being found for rehabilitation work and for the Army and other Services and can, if the priority need is established, be found for the tribunals The most suitable men for tribunals are senior men, the Services are as anxious for youth in the medical branch as elsewhere, and there are many senior men unoccupied or, like a certain major-general AMS recently retired, filling appointments as MOs of Home Guard units This matter will come up again, and although now defeated the forces in favour of tribunals have only retreated to their Alamein line and are planning a new offensive

Sir Stafford Cripps's speech in winding up on the second day seemed to set narrow limits to post-war planning It gave no indication of "a promised land," as Mr Clem Davies said, although speeches by the right hon gentlemen at the Albert Hall spoke of "a land of promises" When the Labour Party's official amendment, dealing largely with post-war reconstruction, is debated next week there will be calls for clearer statements Many members turn with relief from the negative politics of our unified government to the strong appeals by Mr Roosevelt, Mr Wendell Willkie and other American leaders who see the need of building the foundations of the post-war world now This country has given and is now giving great leadership in war, but it is the USA and the USSR, fighting magnificently as they are, who give leadership in post-war politics Members of Parliament at Westminster would sometimes like to feel the wind of these wider political spaces

CENSUS OF DIPHTHERIA IMMUNISATION

A few days ago, in reply to a question in the House of Commons by Prof A V Hill, the Minister of Health gave recent figures showing the absolute number and (where possible) the proportion of children immunised against diphtheria in the different county boroughs at ages under 5 and at ages between 5 and 15 The total numbers, which are very striking, may be read in *Hansard* for Nov 10 (col 2283–86), and the percentage figures, which give the clue to success, are reproduced

breath whenever he exerted himself or walked uphill The coroner asked the son, a heavy dull farm labourer, if this were true He was silent for a time and then said, "Noa" "What," rejoined the coroner, "never short of breath after exertion or walking uphill?" "Noa, he was *never* short of breath but he would puff and blow a hell of a lot"

In England Now

A Running Commentary by Peripatetic Correspondents

ALTHOUGH hair is obviously a most important organ, at any rate in women, it is completely unnoticed in all physiological textbooks. Perhaps one day a hirsute woman doctor or a bald consultant will study the subject seriously. I am often saddened by the sight of hairy women who vary between the presentable girl who has noticed a slight down on her upper lip to the masculine-looking woman with a full black beard like the pictures of the notables of the Victorian era. They all think it is glands and I dare say that most of them are right. Some of the surgeons think that they can do quite a lot about it but I once met a woman who used to perform electrolysis on the faces of Sir Harley Wimpole's patients because they said they could not bear to go back and tell him they were no better. My advice to them is to shave and they are all of them shocked at this suggestion. All women believe that shaving encourages hair growth. The fact is that hairs grow to a certain length and then drop out. If they are cut off at the skin level they appear at first to have been stimulated because they are prickly. Even if this were true it seems to me that it would be better for these unfortunate women to shave frequently rather than go about with beards, but very few of them will agree. I once shaved one of my legs every day for a month so as to make quite sure. When first the hair grew it seemed coarser and more prickly, but now, some years afterwards, I cannot remember which leg I shaved and it is impossible to tell by looking at them. If the radio doctor could be persuaded to use these experiments as propaganda the world would be a more beautiful place.

* * *

I wonder how many girls in that school in Belgium Charlotte Bronte infected with tubercle, and if that particular strain was more stimulating to the imagination than most. Perhaps it is still flourishing in some of our writers—H. G. Wells for instance, whose autobiography tells of repeated hæmoptyses. Commercial possibilities there. "Mixed Haworth Tuberculin for Novelists", "Try our H. G. W. injections for inventors, recovered by our own investigators and made in our own laboratories." I wonder how far bacterial toxins do act as mental inflamers—or I suppose the right way of putting it is, when the brain acts defensively against toxins, to what extent do they give rise to strange picture-thoughts? The depression after flu, for instance, is really the body, advised by the toxin, saying "I'm not fit, I'm vulnerable, I'm going to lie low." If it does go on to paint pictures of coffins, corpses, and one's latter end, well, that's just too bad.

I wonder how long the organisms of our intestines which we now regard as symbiotic have really been so. Even now under certain conditions some of them are ready to go back to the short-sighted policy of attacking their host. Damn them, why can't they read Kropotkin! From the large number of immunes and carriers I suppose the diphtheria bacillus is becoming symbiotic and perhaps wholesale immunisation will hasten the process. I have a sneaking suspicion that your perfectly healthy man according to modern ideas, Grade A, bacteria free except for the symbiotics, might be good at ploughing and plodding, and that's about all. From the bacterial point of view the fittest man is the one who is immune to or on terms of symbiosis with the greatest number of organisms. Of course, our rufulous politicians haven't the scientific education to begin to think out these problems. They are still in the conceited Homo sapiens stage. They think Mr Morrison is a great minister, whereas in fact it is Mr Morrison + *B. coli anti-communist* + *B. backchatia* + the antibodies to the alkaloids of tobacco and gingerbeer + Unc. Tom Cob et al. which is a great minister. They ought to do what I've done for the last three days—get flu, go to bed with the Brontes, counter the depression with a glass or two of rum, and try to think.

* * *

Insufficient attention, both by examiners and the general medical public, has been paid to the theory of Little Men. It is only mine by acquisition. The first time I heard it produced was in a seafood parlor in New Haven, Connecticut, when a young American student confided to me that gastric ulcers were by a lot of little men with picks. Since then workers have produced new suggestions; it was medical registrar who pointed out that Laocoon was study of Little Men wrestling with spirochætes, and fellow-student who suggested that flatus was due to whole lot of Little Men testing the contents of the bowel with Kipp apparatuses. The theory actually has no limits. How does the pituitary know the ovum been fertilised in the fallopian tubes? There is a long chain of Little Men and they shout to one another along the echoing vessels of the body. "She's got it!" they shout, and the wise Little Men of the pituitary pull levers and keep the endometrium receptive. And then there are the eager Little Men from the thyroid, so anxious to see the view that they crowd forward in the eyeball and produce exophthalmos. Or the drunken Little Men of chronic gastritis, which they produce by their mad Bacchanal cavortings over the rugæ. You can think of some others for yourself, but don't try them on the examiners. As usual, they are behind the times; their cortical Little Men are all bound up in red tape and textbooks, reluctant to exchange a new idea on their Little Telephones.

* * *

Now that this war has got into its stride one's car more and more becomes a receptacle for a diversity of creatures and things. I don't object to the creatures: the Servicemen and women on leave who have missed the last bus, the farmwife returning from the town heavily laden with her shopping basket, the evacuees who scrounge lifts to and from school whenever they can and line the running boards if there is no room inside, the goslings, the young pullets or even the nanny goats who from time to time have to be taken along to visit their boy-friend up the road. It is the miscellany of inanimate objects liable to be encountered unexpectedly in the back of the car that makes one fear for the shape of things to come; the week's groceries, for example, dumped in beside a couple of placentæ wrapped in newspaper which I collect for a colleague morbidly interested in such things; the crate of empty bottles to be taken down and replenished with thin beer at the local off-licence (terms strictly cash), the housemaid's shoes which have been repaired by the cobbler next door to the surgery ("doctor won't mind takin' 'em, I'm sure"), the flasket containing the soiled linen which has to be taken down every Friday and swapped for the clean; the shotgun and cartridge-belt (just in case we have half an hour to spare, you know), the vast bin containing pregnancy-urine—a valuable source of APL (whatever that may be)—which I salvage for a chemist; a couple of turnips from a grateful patient—all these and more, to say nothing of one's ordinary stock-in-trade. The other day on opening my accident-bag I scattered a shower of grain upon the floor. Heaven knows how it got there. "Oats, by Jove!" said my patient, "not wild ones, doctor, I trust?" Facetious ass.

* * *

It's all rot (said my friend the ship's adjutant) that when a ship is torpedoed and sinks she sucks you under if you can't get clear. What you have to look out for is things like pianos coming up quick and hitting you hard on the bottom. Very painful they can be, I'm told. My O.C. troops is always worrying about his pension. Keeps me up till two in the morning going through orders about procedure in the event of the ship being torpedoed just to make certain he's covered. But the other night he had a bright idea. "Why, ol' boy," he said, "if the ship sinks you and I and the captain have to go down with her. We're sure to be drowned so there's no need to worry whether I'm covered or not!"

* * *

A man dropped dead in the front garden of his cottage after walking home from work. The last part of his journey had been up a steep hill. The post-mortem examination showed a very large myocardial scar and advanced degeneration of his coronary arteries, one of which was thrombosed. At the inquest, I said that I doubted the statement made by one of the witnesses that he had been in perfect health till he died so suddenly, for I felt sure he must have suffered from shortness of

Letters to the Editor

DOSAGE OF VITAMIN D

SIR,—There is a mis-statement in Miss Morrison's letter of Nov 14 on rickets in the breast-fed infant She says, " If cod-liver oil is used, then the Government compound is to be chosen since much less need be given " The Government cod-liver oil contains no more vitamin D than the ordinary cod-liver oil with which we are familiar, it is referred to as cod-liver oil compound because the strength is kept constant (100 units vitamin D per gramme) by the addition of arachis oil where necessary It is hardly surprising that this mistake is made, it is being made all over the country The reasons for this are (1) that the dosage is so small (5 drops up to ¼ teaspoon twice a day in the first six months), (2) that the product is referred to as a " compound " The effect of recommending these very small doses and calling the oil by the name of compound is well seen in Miss Morrison's letter, she assumes (and who would not?) that the oil has been reinforced by the addition of a concentrate or high potency oil

The special subcommittee of the British Pædiatric Association, which recently considered vitamin D dosage in infancy, recommended 700 units daily as a safe dose for most babies during the first year (see *Lancet*, Oct 17, 1942, p 460) About 700 units of vitamin D can be obtained from—

4 minims or 8 drops of ' Radiostoleum ' (BDH)
5 minims or 10 drops of halibut liver oil (Crookes)
6 minims or 12 drops of ' Adexolin ' (Glaxo)
140 minims or 280 drops (about 2 teaspoons) of cod liver oil, or cod liver oil compound
280 minims or 560 drops (4 teaspoons) of 50% emulsion of cod liver oil

It will be found that most of the manufacturers' droppers deliver ½ minim

If the Government reinforces the compound, as the subcommittee suggests, so that a teaspoonful contains 700 units of vitamin D, endless trouble and confusion will be saved

Finchley　CECILE ASHER

TRACE ELEMENTS

SIR,—The Nutrition Society meeting must have given the impression to those who attended it, and also to those who only read your careful report of Nov 7, that the trace elements are of little importance in medicine But enough is in fact known of their physiological action to justify their clinical use For instance, manganese is intimately associated with vitamin B_1, a quantitative relationship between the two being necessary, at least in the rat, for their proper utilisation by the body (Perla, D, et al *Proc Soc exp Biol N Y* 1939, 42, 368) E Hamamoto (*Orient J Dis Infants*, 1935, 18 37) found the manganese in the livers of children dying from beriberi was half that of children dying from other conditions Phosphatase formation and bone metabolism is also related to manganese (Combs, G F, et al *J Nutrit* 1942, 23, 131) Zinc is reported by W G E Eggleton (*Biochem J* 1939, 33, 403) to be reduced in the epidermal structures in beriberi, and the fundamental necessity for this element and copper in metabolism is pointed out in your report of the Nutrition Society meeting

A dietetic deficiency of the trace elements in man—as was suggested by R McCarrison (*Ind J med Res* 1927, 14, 641) for manganese—probably occurs, since, apart from the findings in beriberi, the distribution of zinc and manganese in foods largely follows that of the vitamin-B complex Indeed, it has been thought that some of the symptoms of a vitamin-B deficiency are really due to a deficiency of the trace elements This would explain why in the treatment of beriberi foods rich in the vitamin-B complex, and so in the trace elements, are necessary in addition to the specific vitamins Quicker recoveries might follow giving the trace elements themselves The present habit of giving large doses of synthetic members of the vitamin-B complex, instead of wheat germ or yeast which contain also trace elements, may cause a relative deficiency of the trace elements necessary for the metabolism of the vitamin-B complex This relative deficiency may be an important factor in limiting the effect of increasing the dose of synthetic vitamins Therefore it would seem reasonable to give a mixture containing zinc, manganese and copper whenever synthetic vitamins are being prescribed My own impression is that such a mixture is of value

Wimpole Street, W 1　FRANKLIN BICKNELL

CONTROL OF VENEREAL DISEASE

SIR,—On April 28th last, as your Parliamentary Intelligence testifies, I asked the Minister of Health " whether, in view of the rise in the incidence of venereal diseases and the danger of dissemination of these diseases in the Armed Services from sources outside the control of commanding officers, a recent instance of which has been furnished to him, he will grant powers to medical officers of health to have persons of both sexes, who are suspected as being sources of infection, examined and, if necessary, treated " My question was prompted by a visit from a constituent, a young surgeon squadron-leader, medical officer to a certain Air station where, in the previous few weeks, thirteen cases of infection with syphilis in the unit were brought to his notice, all of which were traced to a single source This officer came to see me at the House with his close friend, my son, the late Flying Officer E B Graham-Little, killed on active service six weeks later It happened at the time of this visit that there were two other medical members of Parliament within call and we enlisted their advice in actually framing the question, it was, indeed, at their suggestion that examination of both sexes was insisted upon so as to avoid any opposition on the ground of sex differentiation The Minister replied " I am considering what action can most appropriately be taken to deal with the problem to which my hon friend refers "

I received some friendly admonitions, as no doubt the Minister also has done, that it would be undesirable to discuss on the floor of the House the provisions to meet this position and the expedient now adopted by the Minister of making use of Defence Regulation 33b avoids this stumbling-block I think the Minister has acted wisely in postponing, at any rate for the present, notification, but I think this may become necessary to meet more effectually this very serious cause of disturbance of the war effort Although the rise in the incidence of syphilitic infection, for which alone of venereal diseases the figures were given in the recent report by the Minister of Health, has been much greater in the Services than in the civilian population, there is evidence to show that the infection is gravely hampering the industrial war effort It is to be hoped that the medical profession will give its wholehearted support to the Minister of Health

House of Commons　E GRAHAM-LITTLE

REHABILITATION v SICK PAY RULES

SIR,—Now that rehabilitation is receiving so much attention it seems odd that the rules of some friendly societies and the interpretation placed on them by some of their members should pass unchallenged Some societies, of course, have framed their rules quite sensibly, but in some a sick member is forbidden to perform any labour, and the interpretation given to this is sometimes so strict that a convalescent cannot even pull up a weed in his allotment without running the risk of being reported by a fellow member and of being penalised One big society, for example, has a rule for its members on sick pay which reads as follows

> " Any member who　shall be found gambling, or in a state of intoxication, or performing any labour, or transacting any business for profit of any kind whatsoever, or indulging in any sport likely to retard his recovery, may be *fined a sum* not exceeding 10*s* for the first offence, and for the second and each subsequent offence, a sum not exceeding 20*s*, and he shall receive no further sick benefit until such fine has *been paid* "

One of its members who is ordinarily my patient has recently been attending a hospital for many weeks for massage and exercises, following an accident to a shoulder, and he has been docked of part of his sick pay because he was seen punting himself across the river

Of course it is important to have rules to prevent absenteeism and the abuse of sick pay, but it should not be difficult to frame those rules so as to give a reasonable latitude to the convalescent It may be less easy however to educate the members of these societies, and to make them see the importance of suitable occupation in

below The estimates were made by the authorities themselves (Reading and Wigan were able only to give totals) Mr Brown remarked that present circumstances, in particular abnormal movements of population, do not permit of statistical calculation of the ratio of the number immunised to the total population But we have taken the liberty of rearranging the table in conformation with the areas of the country used by the Registrar-General in his *Weekly Summary*, and of adding a brief summary

QUESTION TIME

Beveridge Report

In answer to a question Sir **Stafford Cripps** stated that it was anticipated that Sir William Beveridge's report would be published at the end of November

Rushcliffe Committee

Mr E **Brown**, replying to a question, said that the last nominations for the Rushcliffe Committee were received early in November, 1941 Approximately eight meetings of the full committee have been held, fifteen meetings of the employers panel and twelve meetings of the nurses panel Many of the meetings have extended over more than one day In answer to a question on Nov 10 Mr Brown announced that Lord Rushcliffe hoped it would be possible to submit a first report early next year

Lung Disease among Miners

Sir **William Jenkins** asked the Home Secretary what action he had taken to implement the report of the Medical Research Council into lung diseases among coalminers in South Wales, if he was aware that the disease was on the increase, and would he take steps forthwith as the matter was vital for the mining industry —Mr H **Morrison** replied The Minister of Fuel and Power and I are fully alive to the urgency of this matter and are anxious to deal with it at the earliest date possible Consultations with a view to securing agreement have been in progress with the representative bodies concerned, but are not yet complete

NHI Capitation Fees

Sir **Leonard Lyle** asked the Minister of Health whether he was aware that since the start of the war the general body of insurance practitioners had tried to secure an increase in the capitation fees adequate to enable them to meet the extra cost of war time conditions and the increased work involved, the increase suggested being 2*s* of which only 9*d* was approved, and whether he had reached a decision on the direct representations made to him on this subject by the Insurance Acts Committee of the British Medical Association —Mr **Brown** replied I agreed that from the beginning of this year the capitation fee should be increased from 9*s* to 9*s* 9*d* a year to meet the increase in practice expenses and the loss of private fees from the new class of insured persons. I have considered the request made this year for a further increase and on Oct 17 I informed the committee that I was not able to accede to this request

Nutritional Anæmia

Dr E **Summerskill** asked the Minister whether he had had brought to his notice any evidence of nutritional anæmia in women and children —Mr **Brown** replied My attention has been called to an article in the medical press which stated that evidence of nutritional anæmia had been found amongst certain groups of women and young children I have therefore arranged for iron preparations to be available in all day and residential nurseries and in energency maternity homes the majority of welfare authorities already provide similar preparations at their centres for expectant mothers and young children found to require them

Restriction on Clinical Records

Dr H. B **Morgan** asked the Minister whether he was aware of the growing practice in local authority institutions of the medical officer of health prohibiting the publication of the record of clinical cases or new methods of treatment by medical officers of institutions, under what statutory or other powers local authorities or their medical officers of health did this, whether such restrictions were mentioned in the terms of appointment of such institutions, and whether this restriction on medical publication of observations or new treatment was approved of by the Ministry —Mr **Brown** replied The reply to the first part of the question is no but I shall be glad to consider any particular cases sent to me

Venereal Disease

Mr T E **Groves** asked the Minister whether, in the interests of the general health of the community, he would, in order to minimise the withholding of information concerning venereal disease, confer with the Service departments upon the undesirability of causing any member of the armed forces to lose proficiency or any pay, especially as the armed forces are principally composed of persons withdrawn compulsorily from civil life —Mr **Brown** replied The issue in question is one for the decision of the Service departments to whom I am communicating the suggestion

National Ambulance Service

Mr **Groves** asked the Minister if he had considered the proposal, made to him by the Medical Practitioners Union, that there should be a national ambulance service somewhat analogous to the National Fire Service, and, as its adoption would tend to efficiency, particularly during an emergency, what decision had been reached on the matter —Mr **Brown** replied A reply to the union's proposal was sent on Oct 6, explaining that the consideration of ambulance services is one of the matters included in the surveys of hospitals which are now being made in connexion with the Government's postwar policy During the war the needs are met by the large expansion of the peace time ambulance service represented by the civil defence ambulances, the interhospital ambulances used under the Emergency Hospital Scheme, and the American Ambulance in Great Britain, all of which are coordinated on a regional basis

Oatmeal in the National Loaf

Mr W **Mabane**, parliamentary secretary to the Ministry of Food, informed Mr R **Boothby** that it was proposed to include a proportion of oatmeal flour in the national loaf

TRYPANOSOMIASIS ON THE RUN

Sleeping sickness, on the Gold Coast, was responsible last year for 172 deaths—that is, for 7 3% of the total deaths recorded [1] It is thus a killing disease third only to pulmonary tuberculosis and diseases of early infancy The total number of cases are on the whole fewer, though the trypanosome has made advances in some districts Thus 4332 cases were treated as compared with 5676 in 1940, but increases were noted in 5 stations Surveys of wide areas have been made, and the Kamba Valley was surveyed twice The first of these two surveys showed a falling incidence, the second survey had covered 51 villages at the time of publication and further falls in incidence were found in 29, 14 had the same rate in both surveys, and 7 had an increased rate A clearance and resettlement plan is being followed in the Kamba region, and progressed actively during the dry season, 67 miles of riverside bush have now been cleared and the medical entomologist reports that tsetse flies have been much reduced in the middle reaches of the river *Glossina palpalis* has been almost eliminated and *G tachinoides* reduced so that only one or two flies a week are caught Before clearing, the fly-catching team of four boys caught 300–500 of both species weekly During the year *G morsitans* has come under suspicion of transmitting human trypanosomiasis under natural conditions on the Gold Coast This variety of tsetse fly will be closely watched

---

[1] Report on the Medical Department of the Gold Coast *Colony* for 1941 Crown Agents for the Colonies, 4 Millbank, London, S W 1 1*s*

Extension of EMS Vocational Training Scheme —The Minister of Labour has now arranged that under this scheme disabled people may be trained at certain technical colleges belonging to local education organisations as well as at Government training centres Specialist opinion and treatment will also be available for patients attending the educational centres, and the Minister of Health has issued a list of the technical colleges concerned and the hospitals to which cases from them will be referred (Circular 2549A) he held a combatant commission in the territorial army and up to 1915 commanded the Kent heavy battery and ammunition column But in 1915 he received a temporary commission in the RAMC and for his services he was twice mentioned in dispatches and in 1917 awarded the DSO Later with the rank of lieut.-colonel he commanded the County of London field ambulance and from 1921 to 1923 he was superintendent of the Ministry of Pensions hospital at Orpington The Harveian Society of London elected him president in 1933 Colonel Gowlland married Mary Florence Alexander and their twin sons are now both commanders in the Royal Navy.

Infectious Disease in England and Wales

WEEK ENDED NOV 14

Notifications —The following cases of infectious disease were notified during the week: smallpox, 0, scarlet fever, 2880; whooping-cough, 1155, diphtheria, 940, paratyphoid, 3, typhoid, 13; measles (excluding rubella), 7731 pneumonia (primary or influenzal), 556, puerperal pyrexia 153, cerebrospinal fever, 50, poliomyelitis, 16. polio-encephalitis, 0; encephalitis lethargica, 2, dysentery, 148, ophthalmia neonatorum, 83 *No case of cholera, plague or typhus fever was notified during the week.*

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Nov 11 was 1778, including scarlet fever, 668 diphtheria 265 measles, 194 whooping-cough 147 enteritis 78 ; chicken-pox 43 erysipelas 36 mumps 21, poliomyelitis, 6, dysentery, 53, cerebrospinal fever, 5 puerperal sepsis, 16, enteric fever, 3

Deaths —In 126 great towns there were no deaths from scarlet fever, 1 (0) from an enteric fever, 7 (0) from measles, 4 (0) from whooping-cough. 17 (1) from diphtheria, 66 (10) from diarrhœa and enteritis under two years, and 22 (1) from influenza The figures in parentheses are those from London itself

Rotherham reported the fatal case of enteric fever Willesden had 9 deaths from diarrhœa Birmingham 6 and Manchester 4

The number of stillbirths notified during the week was 208 (corresponding to a rate of 39 per thousand total births), including 24 in London

SMALLPOX IN SCOTLAND

By Nov 20 twenty cases of smallpox had been confirmed in Edinburgh In addition isolated cases have been confirmed in Tranent (one fatal case), Earlston, and Cowdenbeath So far all the patients, except one (a 17-year-old girl whose home is in Edinburgh), have had association with the Edinburgh Royal Infirmary or its convalescent home, but how the infection was introduced into these institutions has not yet been determined It is thought likely, however, that the source of the outbreak was an undetected, mild, ambulant case possibly connected with the recent outbreak at Methilhill in Fife

Vaccination has been available at first-aid posts at three daily sessions, and about 250,000 people have been vaccinated including 35,000 by general practitioners in their own surgeries, and 38,000 in institutions and public works . In Cowdenbeath about 10 000 of the 13,000 inhabitants have been vaccinated either now or during the recent Methilhill outbreak. One suspected case has been admitted to hospital for observation in Perth but as yet general vaccination there has not been recommended A major difficulty has been that many of the cases have presented atypical features Some of the rashes have closely resembled that of chickenpox and in a few cases mild acne and papular urticaria have been simulated

TYPHUS IN EIRE

Thirteen cases of typhus with one death have been reported from a coastal area of co Galway

---

RECRUITMENT OF DOCTORS —To avoid unnecessary travelling it has now been arranged that male medical hospital staffs who are of military age will be medically examined at selected EMS hospitals by a senior member of the staff. But since the decision of unfitness for service must rest with the War Office the Army Council will arrange for the re-examination of a doctor who is not passed by the civilian examiner before he is officially rejected. A doctor who is passed at the civilian examination will not be further examined on behalf of the War Office until he is nominated for a commission.

Notes and News

NORSE DOCTORS

THE Royal Norwegian Government has brought out a little book (*Norway A Handbook* London · J M Dent and Sons) to tell us how our ally is still bearing a part in the war It sets out besides many fascinating things about Norway its countryside, its people and its history Among these is a little paragraph telling how, without consulting Dr Gjessing, the chief physician and director, the Home Office of the puppet government appointed a national socialist to be head attendant at the Dikemark Mental Hospital Dr Gjessing protested, demanding that appointments should be made on professional, not political grounds Then, one day in April, while he was performing an operation a Hird troop broke into the hospital and carried him off The medical organisations of the country demanded his release and full redress on threat of leaving their posts They carried their point and by June 25, the date they had set, Dr Gjessing was back at work This small incident in our own profession is an example of the way Norwegians are holding their own against the Nazi code This is what one would expect from our experience of how bravely Norse medicine is taking its exile in our northern shires, and bearing out the memories of *Feats on the Fjords* so zestfully read in our youth

MORE THAN A MILLION

IN spite of war and war damage, increasing shortage of domestic equipment and staff, the Cecil Houses still offer for a shilling a night bed, bath. tea and bread and butter and facilities for the washing of clothes to women in London who need them Cots for babies cost 3*d* The fourteenth report tells of more than a million beds and cots let to homeless wanderers of the streets since the first house was opened in the slums of Holborn Lately Service girls on leave have found a welcome at the Cecil Houses Three houses are in action and all are open to visitors from 3 30 to 5 PM on Thursdays. In normal times, after the initial expenditure, all the houses are self-supporting, but these are not normal times Clothing is an especially useful gift just now Those who would like to help should write to Mrs Cecil Chesterton, 193, Gower Street. London N W 1

MOBILE FRIENDS

OFFICIAL relief agencies in a war have not the free-lance range of voluntary bodies, especially when these run on wheels The Friends Ambulance Unit[1] is an example of a highly developed mobile organism with tropism towards any acute need Is there a blitz on Coventry, are supplies hung up on the Burma Road do 5000 Chinese in Assam need medical care, have refugees brought cholera from Lashio, could a mobile theatre save lives in the Libyan desert, are village children in Syria going blind from trachoma, does the Emperor Haile Selassie ask help in Ethiopia, must Indians be prepared for raids ? These are just the situations which exert an irresistible attraction for the FAU The motile freely-swimming organism hurries to the spot, waving its wild tail and soon there are young men working hard in hospitals in blitzed areas running a transport service on the Burma Road (where they repair ramshackle trucks and teach internal combustion engines to run on charcoal fumes instead of petrol), contriving and equipping mobile operating theatres, founding a hospital in the jungle almost from scratch, collecting and treating Chinese wounded, checking cholera by treating the sick and inoculating the healthy, helping the surgeon while he is operating in a Libyan mobile unit for 33 days out of 42, feeding 300 Syrian babies on dried milk from America, and beginning a pioneer health service in Ethiopia Women are helping too, planning emergency measures in blitzed towns on lines which can develop into long-term social work, and organising ARP in India These young people are trained for their work During a preliminary eight weeks of camp life they learn first-aid emergency nursing, anti-gas measures field ambulance work and sanitation stretcher drill and fire-fighting, and they take a course of physical training. Those who enter hospital work may hastening recovery The present state of affairs which encourages idleness of mind and body seems calculated to retard it

---

Eton W H W ATTLEE

MIGRATION OF FOREIGN BODIES

SIR,—Prof Lambert Rogers's interesting paper recalls an experience of some twenty years ago A middle-aged man presented himself with a red, slightly tender swelling the size of a hazel nut in the skin of the abdominal wall in the neighbourhood of McBurney's point A dark object could be seen projecting through a tiny orifice at the apex of the swelling, and traction with forceps produced a blue-black feather, corresponding in size and shape with what a fly-fisherman would call a large spade hackle The Keeper of Birds at the Natural History Museum pronounced it to be the feather of a species of pigeon, and on cross-examination the patient confessed to a fondness for pigeon pie I feel that in view of the softness of the quill one can rule out penetration of the skin from without The absence of any symptoms is against the transperitoneal route and the point of exit is far from any subperitoneal track

Bideford M W LITTLEWOOD

JAUNDICE AND URTICARIA

SIR,—In your leading article of Oct 31, you commented on the occurrence of jaundice in US Army personnel following inoculation with yellow fever vaccine and mentioned as a point of note the presence of urticaria in about 20% of the cases, a condition which you state is hardly ever seen in ordinary infective hepatitis In May of this year I saw fourteen cases of jaundice in young adults who had had a prophylactic dose of mumps convalescent plasma about two months previously Four of the cases had urticaria as a prominent feature; in fact, two had been admitted to a skin ward on account of urticaria, the jaundice being overlooked Suspecting the plasma as the causative agent, I reported this outbreak to the Harvard Field Hospital unit for investigation, and no doubt the findings of the investigation will be published in due course

Poole GEORGE CHESNEY

POPULATION DECLINE

SIR,—Your review of *Parents Revolt* asserts that not every one will immediately share the alarm and despondency of Richard and Kathleen Titmuss at their discovery "that the one-child family has come to be the thing" Certainly our own profession has shown its approval of that institution, for we marry well above thirty and the average size of our families is well below two A few of us help on the good cause by charging exorbitant fees for confinements, while others give healthy mothers the impression that they have been foolish in having a fourth or fifth child The overloading of the book with statistics of which you complain may help us face up to unpleasant truths—rather like Churchill's prewar speeches The Titmusses, sez you, want England to have more children than the land (or Empire?) can support I suppose your blood boils to think of the overpopulation of Australia, Canada and the rest, all of them so prudently limiting their population And yet I had thought of Titmuss as the champion of parents with small means, rather like (do you remember?) your own *Aylesbury Broadside* of 1940 One thing, however, the advocates of population decline can fairly claim they did encourage the Nazis to believe that we were degenerate enough in 1939 to be attacked with impunity (look at their flaming headlines "Englands brennende Frage"), instead of letting them wait another twenty years, when we should not have had the man-power to resist them Let us then at all costs keep up our comforts, for, no doubt, the unborn babies' standard of living is much higher in heaven than in the 4- or 5-child family of the comfortably off, necessary even to keep our population stationary And with our new-found knowledge of chemical contraceptives let us slide into a beautiful national euthanasia Did not a recent writer in the *Economist* say we are fortunate in having Ireland so handy as a future reservoir of population? On with winning the war for them and for the others who will take the place of our unborn children!

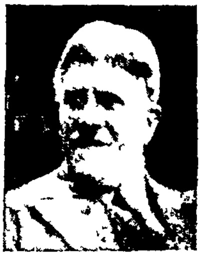
A REVOLTING PARENT

Aylesbury

Obituary

JOHN ORLANDO SUMMERHAYES

D S O, M R C S, LIEUT-COLONEL, R A M C (T)



J O Summerhayes was a remarkable doer but no advertiser Born in 1869, the son of Dr William Summerhayes of Ramsey, I of M, he was educated at Yarmouth Grammar School and qualified from St. Mary's Hospital in 1891 Soon afterwards he and his wife were sent by the Church Missionary Society to the North West Frontier, where cholera and typhus epidemics brought him into close contact with the Indians The admiration which they conceived for him later made easier his work of starting and enlarging dispensaries and an eye hospital, and to-day his friends there still ask, "When is Sumrez Sahib coming back?" Summerhayes was without fear, and when a ghazi, who happily had not a magazine rifle, had mortally wounded an Englishman at Mutch station, J O secured a sword from somewhere, cut down the fanatic with a deep neck wound and then patched him up long enough to secure summary trial and hanging next day He earned his DSO in the last war by his nightly expeditions to bring in the wounded, for the men of the Oxford and Bucks Regiment would not rest content till the CO's recommendation had been accepted After the armistice he was sent to Germany and Austria, seeking out prisoners of war and sending them home Accompanied only by his batman, he reached the beleaguered and famished Austrian royal family and the cry went round that the English had arrived—only two but enough Disregarding the revolutionaries, he shot enough stags for the needs of the party Then a lady of the court sewed a belt with precious contents round him and he set out to bring the delicate Crown Prince and these valuables to Switzerland The main roads were guarded and he had to cross the frontier by little-used ways, but in the end he handed over the prince safely and had the belt unstitched before witnesses

Even after his return to the humdrum life of a GP, first at Thame and later at Newhaven, the unexpected was apt to come out, as when he poked his stick through the window of a patient who needed fresh air and was not getting it At Newhaven he gave of his best to a great panel practice which he had built up, and for the last three years he was also local senior MO of the RAMC, till grave illness led to a serious operation in London, where he died on Oct 28 A fellow practitioner when he heard of his death said, "Summerhayes! the best loved doctor on the South Coast."

He married in 1895 Miss Lucy Currie Their eight children—apart from adoptions—and ten grandchildren were a great joy to him, for he was drawn to children as they were to him

C L

EDWARD LAKE GOWLLAND

D S O, M B LOND, LIEUT COLONEL, R A M C

Colonel E L Gowlland, who died on Nov 1, at the age of 65, had been commandant of the Star and Garter home for disabled soldiers and sailors at Richmond for nearly twenty years He was an expert administrator and his interest went beyond his medical work He knew all about his patients, their family ties and problems, and his business acumen often helped them to start life again in some suitable post At Richmond and at the Sandgate annexe he was tireless in organising entertainments for the patients and staff, encouraging them in pigeon-flying, gardening and handicrafts He was a ready friend to those who were in trouble, but woe betide the impostor, for, as an old soldier he recognised the syndrome His hobby was yachting and he was a member of the Tamesis and Royal Burnham yacht clubs

His father was chief secretary to the Office of Works, and he was educated at Christ's Hospital and St Mary's Hospital, Paddington After graduation in 1901 he set up in practice at Faversham in Kent Until the last war

VITAMIN C AND REPAIR OF INJURED TISSUES

GEOFFREY H BOURNE, D SC, WESTERN AUSTRALIA
MACKENZIE MACKINNON RESEARCH FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

(*University Laboratory of Physiology, Oxford*)

The evidence that adequate vitamin C is necessary for repairing damage to both soft and hard tissues is now considerable, though not widely known Supplies of vitamin C from natural sources cannot be obtained as easily now as they could before the war and since a deficiency of this vitamin seems likely to retard healing of wounds and it is important to secure rapid repair of war injuries it seems timely to present concisely the information available

In the older medical writings there have been references to the breaking open of old wounds and the refracturing of old fractures in scorbutic persons The latter finding has been criticised lately (Hertz 1936) Bleeding gums, loosened teeth, and petechial hæmorrhages are often mentioned in the early papers on scurvy Though considerable clinical information about the disease has been available for many years it was not until the first twenty years of the twentieth century that the pathology of scurvy was extensively studied Hölst and Fröhlich (1907) were the first to produce experimental scurvy in animals (guineapigs), they briefly described the pathology This was followed by the work of Hart and Lessing (1913) who produced experimental scurvy in monkeys In 1919 Aschoff and Koch published an account of the microscopic pathology of scurvy and in 1923 Hojer's comprehensive work on the histology of experimental scurvy appeared These two papers showed that, as Hess noted in 1920, from a pathogenic point of view guineapig and human scurvy have many points in common

These publications showed that there was a widespread degeneration of body tissues, the skeleton being severely affected The cells of cartilage were degenerated and the proliferating cell columns disordered Bones became deformed in shape and the marrow changed to a mucoid substance (Gerüstmark) The cortex of long bones became a thin shell as if absorption of calcium was still going on from the inside of the bone but that deposition on the outside had ceased Microscopic changes in the teeth were first observed by Zilva and Wells (1919) There was fibroid degeneration of the pulp and disappearance of the cement substance The teeth also became loose, no doubt owing to the degeneration of the collagenous fibres of the dental periosteum which hold the teeth in position in the jaw (for further details see Fish and Harris 1934)

COLLAGEN PRODUCTION

The most constant change in scurvy, noted by Hojer, was atrophy of the connective-tissue fibres in various parts of the body this was confirmed by Wolbach and Howe (1926) and others and by the finding of Jeney and Törö (1936) that if vitamin C was added to the culture medium in which fibroblasts were being grown fibres were produced more rapidly Mazoue (1937) showed by similar experiments that vitamin C was an active factor in the production of connective tissue fibres and in 1939 he analysed the rate of production of collagen fibres around a mass of kieselguhr injected peritoneally into a guineapig and demonstrated a direct association between the dose of vitamin C and the time of the first appearance of fibroblasts and fibres

Quérido and Gaillard (1939) demonstrated the relation between the vitamin and production of collagen fibres by culturing osteogenetic cells from the chick in three types of plasma (1) from scorbutic guineapigs, (2) from scorbutic guineapigs but with crystalline vitamin C added, (3) from scorbutic guineapigs which had been treated with large doses of vitamin C for a few days before the experiment Hardly any fibres were formed by the cells in the first plasma but in the second and third fibres were formed as rapidly as in normal plasma The cells in the scorbutic plasma showed fatty degeneration Hunt (1941) has shown that although in scorbutic animals reticular (precollagen) fibres may be formed, in the cont[illegible]nce of vitamin C maturation of these precollagen fibres is delayed, further, mature collagen may retrogress—for example, in a scar—if vitamin C is subsequently withdrawn from an animal's diet Precollagen has a low tensile strength, and according to Hunt wounds containing mainly precollagen fibres have poor holding power

Collagen fibres can be reduced by physical means to a condition resembling precollagen (Picken 1940) If for example collagen fibres are heated to 65° C they contract and become reversibly extensible When stretched and then cooled while in the stretched condition they do not contract again, and on further stretching they "flow" like unvulcanised rubber This change in elasticity and in tensile strength therefore involves some change in the linkage of molecules to one another According to Schmidt (1939) collagen fibres are made up of longitudinally orientated polypeptide chains bound together by side-chain linkages It is on the length of these side-chains that the tensile strength of the fibre depends That there is also some chemical difference between precollagen and collagen is suggested by Heringa and Weidinger (1940) who claim that reticular fibres in general contain more sulphur than collagen fibres (2–0 5%) and that this explains the affinity of reticular (precollagen) fibres for silver salts It is difficult to imagine what part vitamin C plays in the transformation of precollagen to mature collagen Presumably it has some effect on the attachment of side-chains whether it does so indirectly, or directly by being involved in the structure of the fibre, it is difficult to say If it is incorporated in the fibre it must lose its identity as a reducing substance, for connective tissue in general has a low vitamin-C content The vitamin-C molecule has a structure resembling that of the hexose sugars and it is of interest that sugars have been found to be present in collagen According to Beek (1941) the sugars may be the "*l*" isomers of *d*-glucose and *d*-galactose Whatever the part played by vitamin C in the production and maturation of collagen fibres there seems little doubt that its presence is essential for both processes

There are two principal views about the part played by vitamin C *in the formation of intercellular fibres* The first, held by Wolbach and Howe (1926), was that "the failure of cells to produce intercellular substances in scorbutus is due to the absence of an agent common to all supporting tissues which is responsible for setting or jellying of a liquid product" This was supported by Dalldorf (1938) The second theory is that failure to form intercellular substances is due to an upsetting of the metabolism of the formative cells (Ham and Elliott 1938, Fish and Harris 1934) In the absence of vitamin C from a tissue there is certainly little development of collagen fibres, but we know little about the way collagen fibres are produced Most workers appear to think that they are formed in association with cells—for example, fibroblasts Dolianski and Roulet (1933) and Jeney and Toro (1936) claim, however, that in explants of fibroblasts collagenous fibres can form in parts of the medium free from cells, but there is no evidence that the fibres they observed were in fact, collagen fibres Danielli (1942) has pointed out that fibres which have an X ray structure similar to collagen can be spun from protein monolayers and he suggests that tissue fibres may be formed by spinning from a layer of protein adsorbed on the surfaces of fibroblasts If this view is accepted one must assume that in vitamin-C deficiency either the motility of the fibroblast is affected (possibly through some interference with its metabolic processes), so that it is unable to spin such fibres from its surface or that there is a failure on the part of the fibroblast to adsorb protein, perhaps because of some alteration in its membrane or in the physical nature of the proteins which are normally absorbed there

WOUND HEALING

One of the first experimental investigations into the effects of vitamin-C deficiency on wound healing was made in 1923 by Ishido, who found considerable delay in the healing of experimental wounds in scorbutic guineapigs Saitta (1929) found delayed healing of wounds in guineapigs fed on a vitamin-C-deficient diet and showed that the application of vitamin-C extracts to the surface of the wound increased the rate of healing whether the animal was kept on a normal or a scorbutic become practically skilled in radiography, blood-transfusion, dispensing and the conduct of an operating theatre In the past year more than 100 members have taken full-time courses in mechanics and driving Those who are going abroad are given lessons in Chinese, French, Hindustani and Amharic These are men and women whose religious convictions prevent them from fighting, but they do not hesitate to share the responsibilities of a world at war, and some have lost their lives in this service The council of the FAU needs £30,000 to maintain through a fourth year the purpose of serving where the need is greatest Contributions may be sent to the Finance Officer, Friends Ambulance Unit, 4, Gordon Square London, WC1

University of Cambridge

On Nov 20 the honorary degree of master of arts was conferred on Mr W A Mitchell, lately chief assistant in the department of pathology The degrees of MB, B Chir, were also conferred by proxy on J C N Westwood and W K S Moore

University of Sheffield

Dr Mary Simpson has been appointed assistant bacteriologist in the university The following external examiners have also been appointed anatomy, Prof R D Lockhart, physiology, Prof E G T Liddell, FRS, medicine and therapeutics, Prof L G Parsons, surgery, Major General P H Mitchiner, pathology and bacteriology, Prof S L Baker, obstetrics and gynæcology, Prof A L Robinson, forensic medicine, Prof S A Smith, pharmacology, Prof W J Dilling, public health, Dr J A Charles

The junior pro chancellor, vice chancellor, Mr Albert Harland, Prof H N Green, MD, and Prof E J Wayne, FRCP, have been elected to represent the university on the committee of management of the Sheffield Hospitals Council

Royal College of Surgeons of England

A meeting of the council of the college was held on Nov 12 with Sir Alfred Webb Johnson, the president, in the chair Mr R Davies Colley, Mr G T Mullally, Mr V Zachary Cope, Mr C E Shattock and Mr E W Riches were re elected members and Mr W H C Romanis was elected a member of the court of examiners Leave of absence was given to Mr H S Souttar to enable him to act as chairman of a mission to report on the medical services for the Armed Forces in India

The award of a Streatfeild scholarship to Miss Enid Sampson was reported Diplomas of public health and of membership (with the exception of T D Kellock, H G McQuade, J R K Preedy, D S Short, Edith Waterhouse and J F R Withycombe) were granted to the candidates named in the report of the committee of the Royal College of Physicians in THE LANCET of Nov 7, p 561

Society of Apothecaries of London

At a recent meeting of the court of assistants of this society, with Sir Stanley Woodwark, the master, presiding, Dr J P Hedley was elected junior warden for the ensuing year in succession to the late Mr Warren Low, and reappointed representative on the General Medical Council Sir Stanley Woodwark, Sir Hugh Lett, Dr Hedley and Dr A P Gibbons were appointed to give evidence on behalf of the society before the Inter departmental Committee of the Ministry of Health on Post War Hospital Policy and the Organisation of Medical Schools Prof W G Barnard was appointed examiner in pathology

Major Hugh William Davies was clothed with the livery, Henry Michael John Rowan was admitted to the freedom by servitude, and George Payling Wright, Eric Roland Webb and Clement Price Thomas by redemption The diploma of the society was granted to R M Erdman

Royal Society of Medicine

On Tuesday, Dec 1, at 2 30 PM, at the section of orthopædics, Mr Robert Young, Dr J F Brailsford and Lieut Colonel Philip Wiles will open a discussion on painful back in soldiers and in industrial workers On Dec 2, at 2 30 PM, Mr E A B Barnard and Mr L F Newman will read a paper to the section of history of medicine on the life, library and instruments of a 17th century physician At the same hour the section of surgery will meet to discuss varicose veins The opening speakers are to be Mr Reginald Payne and Mr Harold Dodd On Dec 4, at 10 30 AM, Mr F C Ormerod will give his presidential address to the section of otology His subject is to be advances in the study of hearing Afterwards Prof E D Adrian, OM, will speak on the electrical reactions of the cochlea and auditory nerve At 2 15 PM on the day at the section of laryngology, Prof B W Wir Dr Constance Wood and Dr Ralston Paterson will open discussion on the technique of radiotherapy, and at 2 30 at the section of anæsthetics Dr Freda Bannister will speak on the Oxford vaporiser in routine hospital practice

Outlook on Industrial Medicine

On Nov 17 Sir David Munro, medical officer to the Ministry of Supply, speaking to the Conservative Health and Housing Committee at the House of Commons, said that Mr Bevin had given industrial medicine its charter in his order of July, 1940, which laid down that factory managements were to engage doctors and nurses as recommended by the Factory Department Not all firms could engage a whole time doctor, but the part-time system would promote the education—badly needed—of general practitioners in occupational disease For the future Sir David envisaged an institute of industrial medicine, where toxic substances should be examined before being used in industry, and he also foresaw a diploma of industrial medicine—perhaps even a membership and fellowship—under the ægis of such a body as the Royal College of Physicians Medical services, he concluded, were part of welfare, and there should be in every factory a fusion between production, management, health and welfare services This was achieved at the Ministry of Supply by a welfare board of which the parliamentary secretary was chairman

Medical Casualties

The following casualties have been announced

Missing, presumed killed —T/Surgeon Lieutenant D J Naughton, MB DUBL, RNVR, and Surgeon Lieutenant A B Kennedy, LMSSA, RNVR

Prisoners of War —W S/Captain J K Drucquer, MB LEEDS, RAMC, W S/Captain J H McLaughlin MB, RAMC, W S/Captain F J Murray, MB BELF, RAMC, and WS/Captain R J S Walker, MRCS, RAMC

Naval Awards

The RNVR officers' decoration has been awarded to Surgeon Commander E A Gerrard, MD Manc, Surgeon Commander J L Cox, BM Oxfd, and Acting Surgeon Commander E I Puddy, MB Lond

---

REFERRING to the jubilee of the *Clinical Journal* Dr Conner tells us that the late Dr L E Creasy was editor for nearly 20 years before he took over in 1913

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Births, Marriages and Deaths

BIRTHS

DORLING —On Nov 15 at Carshalton, the wife of Mr George Dorling FRCS—a third son

EDWARDS—On Nov 19, in London, the wife of Lieutenant K C S Edwards, RAMC—a son

HUNT —On Nov 16, the wife of Major Alan Hunt, RAMC—a son

MACLEAN —On Nov 15, at Inverness, the wife of Surgeon Lieutenant K S MacLean, RNVR—a son

PEYTON —On Nov 17, at Ipswich, the wife of Captain H N Peyton, RAMC—a daughter

PRINGLE —On Oct 30, in Dublin, the wife of Major T S Pringle, RAMC—a daughter

WOOD —On Nov 15, at North Walsham, the wife of Captain K Duncan Wood, RAMC—a daughter

MARRIAGES

BEDDARD—PORTER —On Nov 7, at Rydal, Westmorland, Frederick Denys Beddard, MRCS captain, RAMC, to Anne Porter

BRUCE LOCKHART—SEDDALL —On Nov 16, at Sedbergh, Patrick Bruce Lockhart, MB RAMC to Mary Campbell Patricia Seddall

MILLS—ROWLEY —On Nov 21 at Birmingham Wilfrid George Mills, FRCS, captain, RAMC, to Margaret Jane Rowley, MB

STEEL—RIDGE —On Nov 14, at Cockfosters, Matthew Steel, MB, to Margaret Ridge

DEATHS

BLUETT —On Nov 19, at Harrow on the Hill Reginald Peter Nutcombe Buckland Bluett, MC, LRCPI

ENSOR—On Nov 22, Howard Ensor, CB, CMG, DSO MB DUBL, major general late RAMC, of Osbornes, Hawkhurst, Kent

HAYDON —On Nov 16, at Highweek, Newton Abbot, Edgar Haydon, MB GLASG

MACGILLYCUDDY —On Nov 18, at Bournemouth, Neill MacGillycuddy, MRCS aged 82

NORMAN —On Nov 17, at Shenfield, Essex George Norman, MB DURH, late of Buckhurst Hill Essex

O'LEARY —On Nov 8, at Newtonmore Inverness shire Elystan O'Leary, FRCSI, surgeon commander, RN

PEARCE —On Nov 19, at Bath Charles Ross Pearce MB EDIN, lieut colonel IMS retd of Longbridge Deverill, Warminster Wilts

Shinya (1922) found adequate vitamin C necessary for successful bone-grafting Ferraris and Lewi (1923) found inhibition of the cellular activities involved in healing a fracture They observed lack of absorption of dead material, lack of formation of osteoid trabeculæ and of cartilage Watanabe (1924) found delay in the healing of fractures in scorbutic guineapigs but not in rats (rats synthesise their own vitamin C) Other workers (Wolbach and Howe, 1925, 1926, Israel and Frankel, 1926, Schilozew 1928, Roegholt 1930, Jeney and Korpassy 1934, Hanke 1935, Hertz 1936, Lauber et al 1937, Ham and Elliott 1938, McLean et al 1939, Lexer 1939, Bourne 1942) have obtained similar results In general they have shown that there is delayed absorption of the fracture hæmatoma, reduced fibroblast activity and deficient production of collagen Bourne (1942b) has shown that optimum formation of bony trabeculæ in injured femurs of guineapigs is brought about by the administration of 2 mg daily of vitamin C (probably equivalent to about 40 mg for a human being) and that anything less than 1 mg (human equivalent about 20 mg) seriously retards the formation of bony trabeculæ

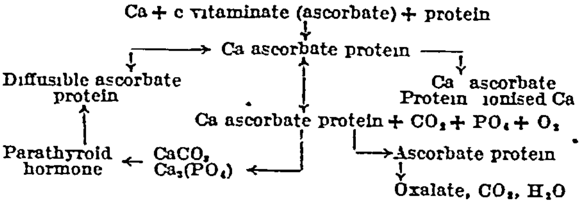
It is impossible then to resist the weight of evidence that vitamin C is essential for the formation of the fibrous ground substance of bone and it is now necessary to consider whether an amount of vitamin C in excess of that required to saturate an animal would further accelerate bone healing Halász and Marx (1932) have shown that guineapigs given an amount of vitamin C far in excess of their normal requirements did not regenerate bone any faster than they did when it was given in normal amounts Studies to decide whether rabbits regenerate bone more rapidly on a diet containing ample vitamin C has given some unexpected results Rabbits are believed to synthesise their own vitamin C and yet Hanke (1935) found that if rabbits were placed on a scorbutic diet although they regenerated bone completely the rate of regeneration was much slowed Lauber and his colleagues (1937) stated that once the normal requirements of a rabbit were satisfied extra vitamin C had no further effect on the rate of regeneration of injured bone It is difficult to appreciate that a rabbit has a normal requirement for vitamin C if it synthesises the vitamin. Giangrasso (1939) and Giangrasso and Gangitano (1939) were able to secure more rapid regeneration of injured bone in rabbits by giving vitamin C The only obvious explanation of these facts is that a normal rabbit can synthesise its own vitamin C but that the healing of a fractured bone calls for more vitamin C than the animal is able to manufacture

In 1 mm holes bored in the femurs of rats I found (Bourne 1942a) that vitamin C did not have any accelerating effect on regeneration of bony tissue Nor in similar holes in guineapigs (Bourne 1942b) was further acceleration of healing observed when amounts of vitamin C in excess (4 mg) of the optimum requirement (2 mg) were injected The general conclusion is that there is an optimum amount of vitamin C required for the regeneration of injured bones and that possibly more extensive injuries require greater amounts of the vitamin (e g , the rabbit work was performed with fractures and extra vitamin C accelerated healing, my work was performed on rats with small 1 mm holes in the bones and extra vitamin did not accelerate healing) and that vitamin C in excess is of no value in further accelerating healing

THE PROCESS OF CALCIFICATION

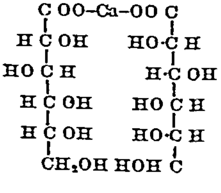
There is thus evidence that vitamin C plays an important part in the production of an inflammatory reaction to injury to organisation of the clot and to formation of the ground structure of the trabeculæ after injury to the bone The next question to be considered is whether the vitamin plays any part in the process of calcification either directly or through its association with phosphatase activity Calcium has been found to be deposited in various tissues in scurvy but it is deposited in an amorphous form This is probably due to the absence of an adequate fibrous matrix Fish and Harris (1934) point out that in the teeth in scurvy calcium salts may be deposited but that there is no matrix available for their reception Bone salt in normal bone is laid down in a crystalline form, in other words the molecules have a specific orientation which is absent from the amorphous masses produced in scurvy Schmidt (1934) suggests that when collagen fibres are first formed they adsorb precipitated inorganic salts and he points out that such fibres possess the ability to orientate particles precipitated in their presence It seems fairly certain from published work that there is a positive calcium balance in scurvy (Hess's (1920) summary of the work of Baumann and Howard) The same finding has been made for adult human scurvy (Lust and Klocman 1912 Moll 1919), infantile (Moll 1919) and monkey scurvy (Howard and Ingvaldsen 1917) Lust and Klocman found a positive balance in the scurvy stage and a negative balance in the healing stage This suggests that in scurvy the calcium may not be deposited on the bones but is being excreted instead, and that in the healing stage the calcium is being used up for deposition on bones, so that excretion falls (Salter and Aub 1931) Barlt and Edelstein (1913) found a diminished calcium content of the bones of a scorbutic infant, but Kapp and Schetty (1937) found that the mineral content of bones remained normal in scurvy Hojer (1923) stated that his histological investigations gave no reason to suppose that the calcium metabolism is primarily disarranged in scurvy He stated that dying tissue generally has a greater affinity for calcium and that this explains the calcification in late scurvy

Humphreys and Zilva (1931) found that calcium and phosphorus retention by guineapigs was lowered in scurvy but only in the last stages of the disease when the whole metabolism was affected Matricardi (1938) found that blood phosphate fell in scurvy and Lucke and Wolf (1938) claimed that extra vitamin C administered to an animal led to a greater retention of calcium and phosphorus but had no effect on the serum calcium and phosphorus If one adrenal of an animal is removed there is an upset of the calcium and phosphorus balance which is restored by the administration of vitamin C (Lucké and Heckman 1938) Lanford (1939) has claimed that orange juice added to the diet of rats caused increased calcium retention Against these observations Henry and Kon (1939) have found that the addition of 2 mg of vitamin C daily to rats had no influence on the retention of calcium Ruskin (1938) and Ruskin and Jonnard (1938) hold that there is an intimate association between vitamin C and calcium, believing that calcium is absorbed from the intestine as calcium ascorbate This compound they find to be highly ionised, non-toxic by injection, and to be adsorbed on to the blood proteins much more strongly than other salts of calcium Below is shown a presumptive scheme drawn up by Ruskin for a calcium metabolism which involves vitamin C

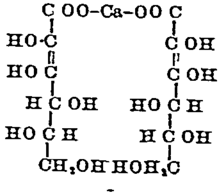


I have found (Bourne 1942a) that if calcium ascorbate is injected into rats it accelerates healing in holes previously bored in their femurs Calcium gluconate, even in the form of the glucono-galacto-gluconate, was ineffective This is surprising in view of the chemical similarity between calcium ascorbate and calcium gluconate , but to some extent it can probably be explained by the greater degree of ionisation of the ascorbate, which presumably secures more effective absorption of the calcium from the subcutaneous tissues and possibly to its greater protein-combining power It is of interest that the double-bond structure of the ascorbic acid is retained in calcium ascorbate and that this substance is therefore an antiscorbutic as well as a source of calcium

Calcium gluconate



Calcium ascorbate



diet Lauber (1933) also found external application of the vitamin to wounds in mice accelerated healing He found that, however, injections of vitamin C into normal guineapigs had no influence on the rate of healing of wounds Against these results Pioto (1936) found that injection or local application of vitamin C into normal pigeons *did not affect* wound healing Mazoué (1937) found that vitamin-C deficiency had a profound effect on the organisation of a clot produced by severing the limb muscles of guineapigs Lanman and Ingalls (1937) carried out direct measurements of the force required to break wounds in normal and scorbutic animals Their measurements were made by distending the abdomen with air and noting the pressure, on a mercury manometer, at which the wound burst Similar observations were made on wounds in the stomach wall The pressure, in mm, at which rupturing took place was as follows

	Animals receiving—	
	2 mg vit C	0 5 mg vit C
Abdominal wounds	160	65
Gastric wounds	70	30

Similar experiments have been carried out by Taffel and Harvey (1938).

Bartlett and others (1942a) found in guineapigs that the strength of the scar was proportional to its vitamin-C content For example, the scars of animals receiving 33 mg of vitamin C twice daily had on average 7 64 mg of vitamin C per 100 g of tissue and burst at a pressure of 258 mm of mercury In guineapigs on a scorbutic diet the vitamin-C content of the scars averaged 0 31 mg per 100 g and they burst at 127 mm of mercury

I have also carried out tests on the tensile strength of wounds (measured by the maximum weight each excised scar could support) made by a complete incision through the skin over each femur of 15 guineapigs, a week after they had been on a scorbutic diet with daily supplements of vitamin C as shown below, there were 3 guineapigs in each group The wounds were allowed to heal for a week while the animals were maintained on the scorbutic diet with the same vitamin-C supplements The results were

Doses of vitamin C injected subcutaneously (mg)	2	1	0 5	0 25	0
Av in g at which scar broke	283	162	154	60	46

It may be seen that there are two dosage levels where there is a distinct drop in the tensile strength of the wound between 2 and 1 mg, and between 0 5 and 0 25 mg The strength of the wound at 0 5 mg is about half that at 2 mg, this result corresponds fairly well with those of Lanman and Ingalls In the group receiving no vitamin C the figure represents the results obtained from only one animal In the other two the scar was so loose that it broke across during excision It would be worth while knowing whether the guineapig doses of vitamin C can be interpreted in terms of human requirements Bourne (1942b) concluded that 2 mg of vitamin C for a guineapig may be approximately equal to 40 mg *for man* These results therefore mean that in a person already saturated with vitamin C 40 mg of the vitamin may be required each day to secure adequate healing of wounds and that less than 20 mg may produce a scar of low tensile strength Other investigations on the strength of scars resulting from skin wounds in guineapigs on normal and deficient amounts of vitamin C have been obtained by Hartzell and Stone (1942) On the 6th postoperative day they found the strength of the wound in sub-scurvy animals was only half the normal From the 8th to 14th days it was a quarter normal

Hunt (1941) has treated human surgical cases with vitamin C, giving 1000 mg of ascorbic acid daily for 3 days to saturate the patient and 100 mg a day to maintain it Other workers have stressed the importance of adequate vitamin C for healing wounds, Lauber and Rosenfeld (1938) showed by silver nitrate staining the presence of vitamin C in healing wounds and its absence in the wounds of scorbutic animals; Wolfer and Hoebel (1940), Holman (1940) and Bartlett and his colleagues (1940) stressed the importance of vitamin C for surgical patients, and Lund and Crandon (1941b) in 58 patients *having operations* on the biliary tract found the incidence of postoperative hernia greatest in patients having low values of plasma vitamin C

Crandon, Lund and Dill (1940) showed that in a placed on a completely vitamin C free diet for 3 wound in the mid-back had healed quite well after days, but that a similar wound made after 6 m the diet showed no signs of healing after 10 days, was a lack of intercellular substance and under the the wound was filled with an unorganised blood Thus after 3 months on a scorbutic diet a wound, by macroscopic and histological evidence, had ently healed quite normally, but we do not know holding power of such a wound We have evidence however, from the work of Bartlett and others (1942b), that if the plasma vitamin-C level falls below 0 20 per 100 c cm there is likely to be reduced tensile stren in healing wounds in human beings As Hunt's made clear there may be plenty of intercellular present in a healing wound, but if most of them composed of immature collagen the scar will have poor holding power and that is the really relevant point as as normal surgery is concerned. The same argument applies to the observations of Fox (1941) In addition, Crandon and his colleagues were reporting an acute experiment What we need to know and what we do not know is the effect of suboptimal doses of vitamin C for periods of 30–40 years, and in particular in babyhood and childhood, on the reparative powers of tissues. Pfab (1927) has claimed that *inferior nutrition* during childhood will cause fractures incurred in later life to heal more slowly, but we have no real proof at present that this is so

Not only is the growth and migration of fibroblasts affected in healing wounds in vitamin-C deficiency but phagocytosis is also inhibited Hunt (1941) has stated that deficiency of the vitamin *delayed* the removal of catgut ligatures "either by phagocytosis or extrusion" Messina and Varga (1937) had previously shown that vitamin C increases phagocytosis in vitro and Tonutti and Matzner (1938) have shown that cells engaged in phagocytic activity in the body including those phagocytosing catgut sutures can be shown by silver nitrate staining (for specificity see Barnett and Bourne 1941) to contain relatively large quantities of vitamin C in their cytoplasm I have *found that* in healing skin wounds of rats these silver nitrate staining cells are sometimes present in the scar tissue within 3 or 4 days of wounding

REPAIR OF BONE

In the first stages of the repair of bone, cellular proliferation and production of fibres similar to collagen fibres are essential preliminary processes to calcification, and it is to be expected, therefore, that a deficiency of vitamin C would delay healing in bone. It has been shown (Bourne 1942b) that, in guineapigs with injured femurs taking a vitamin-C-deficient diet, the degree of healing was proportional to the amount of vitamin C given In the completely deficient animals cells in the cambial layer of the periosteum failed to multiply and fibroblasts did not migrate into the fibrin clot surrounding the injury, in cases where fibroblasts were present fibre formation was reduced or absent and maturation of fibres (estimated by their ability to stain with van Gieson) was delayed In general the normal inflammatory reaction of injured tissue was inhibited, and the change of fibroblasts into osteoblasts was also delayed. McLean and his colleagues (1939) also found delay in the differentiation *of mesenchymal* cells to osteoblasts Hertz (1936) noted a deficient production of collagen and a delayed absorption of the hæmatoma at the site of a fracture (see also Ferraris and Lewi 1923, Watanabe 1924, Wolbach and Howe 1925, 1926) In partial deficiency of vitamin C there is a tendency for collagenous material to appear instead of osteoid (Dalldorf 1938)

These changes in scorbutic animals suggest that fracture healing would be delayed in scurvy and this has proved to be the case Earlier writers were concerned with the fact that old healed fractures softened and became mobile in scurvy (Mead 1762, Marrigues 1783, Bell 1788, *Callisen* 1798, Hammick 1830, Budd 1840), though it seems that they were misled by fresh fractures or separated epiphyses into this belief Moore in 1805 stated that fractured femurs would not consolidate while patients had scurvy Bloch (1912) described scurvy as one of the causes of non-union *of fractures* Lobmayer (1918) reported delay in fracture healing in scurvy later, as the following analysis of multiple burns shows (table I)

More of the cod-liver oil group were infected, but there was little difference in the time of onset of infection between the two groups Infections arising later than the first week appeared after cleansing and retanning

TABLE I

Site of infection	Tannic acid (20 cases)	Cod liver oil (10 cases)	Onset of infection (days)		
			1–4	5–8	10–29
Face (20)	10	10	13	7	
Eyes (15)	6	9	10	5	
Ears (13)	6	7	6	3	4
Hands (16)	11	5	6	6	4
Legs (7)	7		1	3	3

The onset of infection was heralded by the appearance of moist edges and later frank pus, and was associated with greater detachment, cracking and fissuring of the tan after increasing movement of subjacent muscles This was always early and specially noticeable in the face When movement was controlled, as in the hands and legs, the tan separated later Thus we have good correlation between the beginning of loosening of the marginal tan and the onset of infection In most cases infection occurred from the marginal skin as a result of inadequate antiseptic measures This was strictly true as regards infection in the leg and thigh areas, in the face and hands, however, infection from the fauces also played a part

Eyes—Half of the 30 cases showed no conjunctivitis on admission four to eight days after injury, in these the eyelids were either unaffected or only slightly scorched, the eyes themselves were healthy Of the other half, in 10 lids and conjunctivæ were seriously damaged, and in 5 the cornea was involved in addition, ulcers and foreign bodies being present All 15 were infected, in 10 infection was apparent within four days of injury, and in the remaining 5 within the first week In 4 conjunctivitis was noted within twenty-four hours, and irrigation with boric acid lotion was then begun This was probably the only form of treatment before admission, and it was all that was necessary in 2 cases, in hospital mild silver proteinate (‘Argyrol’ 10%) was the antiseptic employed combined with frequent cleansing with wool and saline Liquid paraffin helped to keep the lids soft, the cornea moist, to ease pain and float out pus Since pus ran into the eyes from under the tan, the crusts and tan were removed as soon as possible to obviate this and to permit of free opening and closing of the lids

TABLE II—REAPPEARANCE AND PERSISTENCE OF INFECTION AFTER CLEANSING AND RETANNING OF SEVERE MULTIPLE BURNS

Infection		Face			Hands		
Reappeared after—		1 wk	2 wk	Later	1 wk	2 wk	Later
Lasted	1 wk	3	6	1	2	1	4
	2 wk	1				1	
	Longer	1*		1†	3	2‡	2§

* Otitis media 26th day † Circumorbital cellulitis 58 days
‡ Sequestra 20 and 40 days § Sequestra 60 and 80 days

With these measures the infection was terminated within a week in 5, and within two weeks in 6 cases Corneal ulcers and persistent foreign bodies prolonged the period of infection in 2 cases for three and four weeks Infection of the circumorbital areolar tissues was associated with conjunctivitis lasting for seven weeks in the remaining 2 patients Silver nitrate, 0 5%, terminated the infection of the lids in these One feature of note was that the pus from under the tan and in the conjunctival sac did not appear to damage the intact cornea The early cessation of infection, rapid improvement and excellent prognosis as regards vision in most of these was considered satisfactory

Face, limbs and trunk—Some of the areas cleaned and retanned on admission to hospital became infected again despite careful surgical technique and antiseptic measures In most of these the duration of reinfection was about a week, although the onset of reinfection varied from one to five weeks from the time of admission (table II) Such infections were slight or moderate, and essentially superficial Infection reappearing later than the second week was usually associated with involvement of the deeper tissues In the case of the face, the circumorbital tissues and external auditory meatus were the parts affected, and acute otitis media resulted in one patient on the twenty-sixth day after retanning In some instances the legs became reinfected despite a short succession of cleansings and retannings at five to seven day intervals, followed by the application of tulle-gras and mercurochrome or acriflavine. Infection in these cases was heavy and resistant and yielded, after further cleansing, to silver nitrate, 10%, and retanning with tannic acid As regards the hands, persistent infection was a sequel of ischæmic damage to digits in the group treated with tannic acid, and terminated shortly after the removal of sequestra

TABLE III—BACTERIAL FLORA IN 200 HEALTHY NAVAL PERSONNEL

Organism	Fauces	Skin	Contiguous garment
	%	%	%
Strep viridans	50		
Pneumococci	50		
M catarrhalis	35		
Staphylococci (hæmolysin and coagulase negative)	35	90	80
Staphylococci (hæmolysin and coagulase positive)	20	25	14
Hæmolytic streptococci	5		—

We do not wish to discuss the relative merits of tannic acid and cod-liver oil in the treatment of burns, but it may be remarked that, despite slight or moderate infection, those 5 cases in the oil-treated group which did not require cleansing and retanning progressed favourably, were well healed within twenty-seven days, and had scar-free skin better than that of the most successful cases treated with tannic acid

CAUSES OF INFECTION

The *Staphylococcus pyogenes* was the predominant organism, and in a study of the fauces, skin and clothes of a sample of healthy personnel afloat we have found that organism to the extent of 20%, 25% and 14%, and hæmolytic streptococci in the fauces only in 5% (table III)

From all 22 infected cases the *Staph pyogenes* was recovered from the burn and the duration of infection discussed above refers to the persistence of that organism The other organisms recovered were regarded as additional, and were as shown in table IV These findings apply only to this group of cases

TABLE IV

Organisms	Tannic acid group (12 cases)	Cod liver oil group (10 cases)
Staph pyogenes	All	All
Streptococci (non-hæmolytic)	5 (lasted 1–8 days)	4 (lasted 1–4 days)
B proteus	2 (lasted from 10th to 20th days until exudate dry)	8 (lasted from 8th–10th day for 10–15 days until crusts dry)
Subtilis group		8 (lasted from 8th–10th day for 10–15 days until crusts dry)

Most of the cod-liver oil series became infected with *Bacillus proteus* and some members of the subtilis group of organisms, this occurred about the eighth day and persisted until the crusts of purulent exudate and oil were thoroughly dry Broth cultures of the crusts, however, continued to yield these organisms and the staphylococcus for further periods, in fact, until the crusts separated, proteus and subtilis bacilli could always be recovered, and in this respect they outstripped the staphylococcus in viability

From a review of the case-notes of this series, there is little doubt that chief among the causes of infection are

That there is a connexion between vitamin C and calcification of bone is suggested by the work of Salter and Aub (1931) They showed that in guineapigs on a scorbutic diet and injected with sodium alizarin sulphonate (which forms a coloured lake with calcium ions so that freshly deposited calcium is stained) the bones of the animals were stained red indicating that calcium deposition was proceeding normally In scorbutic guineapigs they found the bones unstained Deficiency of vitamin C therefore causes inhibition of the mechanism which results in the deposition of calcium in bones I have been able to support this result and have found also (Bourne 1942c) that in guineapigs receiving injections of sodium alizarin sulphonate and with small holes bored in the femurs, the repair tissue stained strongly in those receiving injections of 2 mg daily of vitamin C for 2 weeks, less intensely in those receiving 0 5 mg and not at all in those receiving no vitamin C

The work of Gould and Shwachman (1942) suggests that vitamin C may play some part in the deposition of calcium by means of its effect on the phosphatase system of bone They found a lowered phosphatase content of the bones of guineapigs in scurvy, and I have found (Bourne 1942c) that in scurvy the bones of guineapigs stain less intensely with *Gomori's phosphatase technique* than those of normal animals and that the repair tissue filling a small hole in the femur of a scorbutic guineapig also stains much less intensely than similar tissue in normal guineapigs It seems, therefore, that vitamin C may play three important rôles in the regeneration of bone it may promote activity of fibroblast cells and possibly their differentiation into osteoblasts, it may favour the attachment to each other of the polypeptide chains which make up the constituent collagen fibres of the bone matrix, and by promotion of phosphatase activity it may aid in the precipitation of bone salts

SUMMARY

From the results presented in this paper it appears that vitamin C plays a fundamental part in the regeneration of tissues and for this reason it seems that the administration of vitamin C should become a routine in the treatment of any injury Preliminary results with animals (Bourne 1942a) suggest that calcium ascorbate may prove a valuable therapeutic substance for the treatment of fractures, but clinical trials with this substance have not yet been carried out

I wish to thank Roche Products for the vitamin C ('Redoxon') used in the wound healing and other experiments carried out by the present author quoted in this paper

INFECTED BURNS IN NAVAL PERSC

R M Heggie
MB, BSC GLASG
LATELY SURGEON LIEUT COMMANDER RNVR

J F Heggie
MB, BSC GLASG
SURGEON COMMANDER RNVR

We wish to report on a single series of 30 cases severe multiple burns selected from a larger series cases, since they occurred at the same time and subjected to similar transportation All the cases severely burned, mainly as the result of cordite and high temperature flash, the face, including the ey and the hands were particularly affected The themselves were only slightly damaged in a few instan protection being achieved by the very rapid, reflex closing of the lids and the added shielding by hands The ears also suffered The legs, thighs trunk were involved in varying degree

The cases fall naturally into two groups in an experiment devised unwittingly by the medical officers cerned with early treatment In one group (20 tannic acid was employed throughout, in the group (10 cases), tannic acid (5% aqueous solution, application in compresses) having proved inadequate, dressings of cod-liver oil were used after cleansing admission to hospital, 8 of the 20 cases treated with tannic acid were not infected, 4 were moderately infe at the margins, and 8 were so infected as to cleansing and retanning, of these last, 2 later reinfected All 10 treated with cod-liver oil were infected, 5 moderately so, the other 5 were cleansed and retanned (tannic acid), and of these 3 became reinfected, only 2 not becoming septic again

ONSET OF INFECTION

The face and eyes became infected early, usually within the first four days and in all cases within the first week, the limbs were usually involved slightly

repeated, initial or continued protein loss, slow recovery from anæmia and the like As regards the time taken to heal from the cessation of infection, there was no appreciable difference between the oil-treated and the tan-treated group , and these have not been differentiated in table V

TABLE V—DELAYED HEALING IN 30 CASES

Infection	Duration of infection (days)	Total time to heal (days)	Time to heal from end of infection (days)	
None	—	12–25	12–25	Normal time
Slight	4–14	17–35	13–21	
Moderate	15–20	35–45	20–25	
Gross	20–45	50–100	30–60	
(1)	45	72	27	
(2)	82	117	35	
(3)	40	83	43	

CONCLUSIONS

The conclusions to be drawn from these observations on the bacteriological findings and the time and mode of infection, are that adequate early antisepsis is necessary and that like measures must be continued Where facilities for relatively leisurely cleansing are available, antiseptics should be applied to the raw area and the marginal skin before and after tanning Where such facilities are not available, or are limited by reason of large numbers requiring treatment at the same time, the tanning agent should be accompanied by a suitable antiseptic or should be in itself a suitable protein coagulant and antiseptic—for example, crystal violet, 1%, or silver nitrate, 10% From the evident efficacy of crystal violet when used alone, it seems to us an unnecessary expense to incorporate a salt such as sodium ethyl mercurithiosalicylate in a crystal violet jelly , infections due to *Bacillus coli* and like organisms are uncommon and crystal violet is effective against staphylococci and streptococci If an area is not to be tanned it should be rendered as bacteriologically clean as possible, and the adjacent skin margins should be treated with antiseptics at the outset; an efficient antiseptic containing tulle-gras should then be applied, such as the one containing 60 parts of proflavine oleate 1% in liquid paraffin and 40 parts of soft paraffin which we have already described[2] We do not agree that the use of tulle-gras with moist saline dressings, frequently or occasionally changed, minimises the risk of infection On the contrary, until the fibrin layer which forms in the serous exudate on the surface is left undisturbed and allowed to dry these moist, open wounds are particularly liable to reinfection

The keynote in treatment should be rest and lack of interference After the elimination or minimising of infection by full aseptic technique and adequate antiseptic measures there is no better dressing than a dry occlusive one, preferably a coagulum, for this is a close approximation to Nature's method of healing under a scab

SUMMARY

A group of 30 cases of severe multiple burns, sustained at one time in like circumstance, is reviewed with regard to onset and course of infection, to coagulants and antiseptics employed in initial and subsequent treatment, and to the time of healing

The first-aid coagulant, tannic acid in 2½–5% aqueous solution, applied in compresses was not altogether satisfactory At the first full treatment 10 cases were cleansed and treated with cod-liver oil and on reaching the base hospital about a week later all of this subgroup showed infection 5 moderately infected cases progressed favourably despite mixed infection, exudates dried, crusts separated, and were healed by the twenty-seventh day, without blemish , 5 much infected were cleansed and tanned (tannic acid 10% or 15%) Of 20 cases further tanned (tannic acid 5%) at the first full treatment, 8 were not infected, 4 showed marginal infection, and 8 seriously infected were cleansed and retanned on reaching hospital. Of the 13 retanned, 8 remained clean , infection persisted in 5 with ischæmic changes and deep tissue damage, and cleansing and tanning was repeated

Infection was always associated with separation of the margins of the coagulum, initially or later, and was related to muscular and general movement , it was seen early in face, eyes and ears, later in hands and legs

Staph pyogenes was the principal organism in all cases , non-hæmolytic streptococci, *B proteus* and *B subtilis* were additional in some, the last two particularly in the cod-liver oil group

Factors contributing to infection were inadequate coagulation at first-aid and first full treatment, and ineffective antiseptic measures at these times

The antiseptics used (one application) delayed infection as follows acriflavine for two to seven days , mercury perchloride five to ten days , mercurochrome for five to twelve days , silver nitrate for fourteen days or more Gentian violet and brilliant green were very effective, but it was necessary to repeat the applications, especially at margins In fully established sepsis, lymphagogues were effective in removing tan and diminishing sepsis ; remaining infection was then more easily treated by antiseptics

After cessation of infection which had lasted three weeks, healing occurred within normal time—three weeks or thereby Infection persisting longer, up to six weeks, and greater tissue damage, prolonged the healing-time to four or six weeks after the infection had cleared

The essentials for the prevention of infection are thorough and efficient antiseptic measures to the burned area and marginal skin, formation of a sound coagulum at the outset, continued application of antiseptics to skin margins, rest and lack of interference

We wish to thank the Medical Director General of the Navy and Surgeon Rear-Admiral Stephens for permission to draw from many case notes, and the many medical officers concerned

POSTVACCINAL ENCEPHALITIS

THOMAS ANDERSON
M B GLASG, F R C P E
PHYSICIAN SUPERINTENDENT

PETER MCKENZIE
M B GLASG, D P H
SENIOR RESIDENT ASSISTANT PHYSICIAN

KNIGHTSWOOD FEVER HOSPITAL, GLASGOW

THE appearance of smallpox in Glasgow in June–July, 1942, resulted in the vaccination of a very large number of persons Accurate figures are as yet difficult to obtain, but the medical officer of health in his report states that over 617,000 doses of lymph were issued in respect of persons living in Glasgow and neighbourhood , further 378,315 persons were dealt with at the public vaccination clinics It is estimated that the addition of vaccinations conducted by general practitioners and at various works, factories and hospitals would bring the total to about half a million Most of these vaccinations were carried out in July The vaccination of such a large number of persons in such a short time is probably without precedent

The possibility of postvaccinal complications was foreseen, and, accordingly, an observation ward was set aside in this hospital so that all such cases reported to the Public Health Department might be dealt with in one place During the ensuing weeks 29 cases were admitted Most of these consisted of different skin manifestations which for social or other reasons warranted admission to hospital It is to record 14 of these cases, admitted to the hospital as postvaccinal encephalitis, that the present report has been prepared They comprise all such cases which came to the knowledge of the Public Health Department

EPIDEMIOLOGY AND CLINICAL FEATURES

The main features of this group of cases are shown in the table It will be seen that in 7 the notified diagnosis was sustained , in 5 on clinical grounds and in 2 on the results of microscopic examination of tissue

Incidence —We are trying to trace any possible cases which were not notified We do not think there can be many It is clear that the incidence of encephalitis varies within very wide limits Thompson (1931) produces a table in which the incidence varies from 1 12 inadequate initial tanning and inadequate and ineffective antiseptic measures within the first forty-eight hours after injury—the inadequate character, in short, of the first-aid and next immediate treatments This is not an indictment of the painstaking personnel conducting the treatment under the difficult conditions of war-time service afloat, but rather of the therapeutic agents employed.

---

[2] Heggie R. M , Gerrard, E A , Heggie, J F , et al *Lancet*, 1942, i 347

METHODS OF TREATMENT

Tannic acid —From this series and from our experience of other cases reaching hospital, it has been evident that tannic-acid compresses (2½–5% solutions) are ineffective as regards resulting tan, while tannic acid applied in jelly form (10–20%) has been effective and yielded results equal to those obtained in peace-time from the application of tannic acid by spraying and drying Furthermore, the tan from those stronger applications has withstood the test of transhipment and travel to base hospital A weak solution of tannic acid brings about coagulation slowly, and the area requires to be dried and the solution reapplied many—even 20—times at intervals to secure a satisfactory coagulum During this protracted time of coagulation serous exudation continues and will continue for many hours, resulting in increased shock and even floating-off of the tan Practical experience has shown that tannic acid in concentrations of 10–20%, either swabbed on or applied in jelly-form, brings about rapid and effective coagulation and aids materially in reducing pain and loss of serum from damaged capillaries, and consequently diminishes shock This is also the opinion of those who have contributed to the recent EMS Memo on the subject (EMS/GEN/243), yet Clayton and his colleagues [1] are surprised that " even so elementary a question as the most effective concentration for the tannic acid solution is not settled in medical literature " They appear to have overlooked the fact that, in peace-time practice at least, the more dilute solutions were employed in spraying, drying, respraying and redrying, and that the end-result of such measures is similar to the single application of the stronger solutions

Cod-liver oil —We cannot discuss the comparable rôle of cod-liver oil, since it was not used as a primary coagulant In this series it was used at the second treatment (i e , the first full treatment) as an alternative to tannic acid In most of these cases a moderate coagulum resulted But having regard to the almost invariable infection of this group, and a serious degree of shock in one case on admission to hospital, it seems reasonable to conclude that even as a late coagulant the action of cod-liver oil is slow and equal only to that of tannic acid in weak solutions Clayton and his colleagues quote Lohr, who treated nearly 1000 cases of burns, as stating " the cod-liver oil treatment of burns does not influence primary shock " (presumably this is related to the coagulation effect) " but is remarkably effective in controlling the secondary infection of large areas A rapid cleansing of the wound follows its application, and epithelialisation is stimulated to a degree not seen in any other form of treatment " Our conclusions as regards the coagulating quality of cod-liver oil thus appear to be in accord with Lohr's Our findings are quite different when infection is considered, but it should be remembered that Lohr's cases were encased in plaster, our cases were not so enclosed, in addition they were subject to handling in transhipment, and both these things probably contributed to infection At no time have we observed cod-liver oil acting as a stimulant to epithelialisation, Lohr's cases probably healed quickly because of the absence of infection, and the immobilisation afforded by the plaster casing

Gentian violet was not used in this small series In 1% solution or jelly-form it affords a good coagulum, but we have not seen it used in extensive multiple burns in the primary treatment

Antiseptics in initial treatment —Antiseptics should never be allowed to replace surgical cleanliness, but some antiseptic must necessarily be applied to the raw area before tanning, and repeatedly to the tan and the marginal undamaged skin if infection is to be prevented From this series and from other cases we have formed some opinion of the value of the antiseptics commonly used. Cleansing with spirit soap followed by the use sterile saline and later ether, even when carried out all due surgical care and attention, is insufficient prevent infection and is harmful to the patient, to shock by considerably increasing loss of body heat. One of the non-irritant synthetic detergents, in aqueous solution, should replace the relatively inefficient spirit and ether soaps commonly used We have judged the effect of the antiseptics employed by the day on which infection was noted clinically. This was the only method possible for assessment of cases before admission, and we continued to use this standard afterwards, so that our results might be comparable This is admittedly a rude yardstick, and presumes that the chances of infection were equal in all

Acriflavine, 1/1000 aqueous solution, delayed infection for two to seven days , mercury perchloride, 1/5000 aqueous solution for five to ten days , silver nitrate, 10% aqueous solution, when combined with retanning, for about fourteen days (i e , until the marginal tan began to separate), and mercurochrome for five to twelve days In contrast, crystal violet and brilliant green were effective in preventing infection altogether, when used in conjunction with tannic acid coagulation , they were applied to the tan and marginal skin in 0 1%, 0 5% or 1% aqueous solution It must be pointed out, however, that when employed in 1% solution they were reapplied as a rule every fourth or seventh day, and when in lesser concentration, sometimes every day This contributed considerably to their efficiency The cases which we have seen treated with crystal violet alone, 1% in a jelly, have not been infected, but such burns were mainly of relatively small areas, face, hands and forearms, and seldom of the third degree , in 3 of the 14 the jelly was reapplied to the margins on the fourth and seventh days Thus our assessment of the order of usefulness of these several antiseptics is really only true as regards their original single application to the affected area and immediate surroundings and does not apply to their value on repeated application The necessity for reapplication is obvious

Antiseptics in established sepsis —None of these antiseptics was very effective alone in the presence of moderately heavy infection when applied to infected granulating areas after shedding or removal of tan The number of organisms fell to some extent but the infection appeared to persist in the deeper parts of infected tissue In cases not retanned, lymphagogues were the most effective agents in ridding an area of most of the infection from superficial as well as deeper zones of the granulations, and sometimes these alone rendered such areas sterile after their application every four or eight hours for three days Lymphagogues were also of much assistance in separating sloughs and loosening tan from areas of third degree injury When complete sterilisation was not achieved at the end of three days, proflavine, 0 1% in normal saline or in buffered isotonic solution, usually secured complete sterilisation in a further one to three days The striking value of lymphagogues suggests that in most cases the majority of the infecting organisms were in the related lymphatic channels and could be dislodged mechanically by increasing lymph flow

Chemotherapy —Of the series of 30 cases, 5 received sulphapyridine in full doses for four to six days, the initial dose being given on any day from the second to the eighth No difference was noted in the degree of infection present between this subgroup and the remainder on admission If sulphathiazole had been used a greater bacteriostatic effect might have been evident

RATE OF HEALING

Most cases healed to a small extent while moderate infection continued , once the infection was checked healing as a rule proceeded as in normal uninfected areas In some instances, however, where infection persisted for more than three weeks there was delay (table V) That infection was not the only factor concerned in delayed healing is seen from 3 of the grossly infected cases of the series In these, infection lasting forty-five, eighty-two and forty days was associated with healing over twenty-seven, thirty-five and forty-three days The first of these can be regarded as having healed in approximately normal time , delay in the others is not very great—certainly not as great as in a few others we have seen—and was associated with such additional factors as tissue deeply affected, dressings too often

ENCEPHALITIS WITH SKIN ERUPTION AFTER VACCINATION

TRANSFUSION OF IMMUNE BLOOD

R. VAUGHAN FACEY, B.M. OXFD
MAJOR, R.A.M.C.

SINCE Luksch recorded a case of postvaccinal encephalitis in 1924 some hundreds of cases have been notified from many different countries but in spite of extensive inquiry the ætiology of the condition is still uncertain. Generalised vaccinia is another well-recognised complication of vaccination but most observers deny that it ever coincides with encephalitis. The case to be described presented characteristic features of encephalitis of postvaccinal type arising on the same day as a generalised vesicular eruption.

CASE-HISTORY

A gunner aged 19 had had no previous illness and there was no family history of nervous or allergic disorder. He had not been vaccinated. Primary vaccination, with one insertion, was carried out on June 6, 1941. There was a normal "take." He remained fit until June 30 when he noticed a few spots like insect bites on his ankles. He first reported sick with these on July 5, when he also complained of a slight sore throat. Next day (30 days after vaccination) the rash became generalised, the temperature rose to 104° F. and he was admitted to hospital. His only symptoms then were slight sore throat and some skin irritation.

On July 6 his temperature was 103.8° F., pulse rate 116 and respirations 22 per min. The face was sallow. He was stuporose but able to answer simple questions. There were periods of restlessness with athetotic movements of the upper limbs; skin was hypersensitive; he shouted and jerked his limbs on being touched. The pupils were equal and reacted normally to light and accommodation. All reflexes were brisk; plantar responses flexor; there was no paresis, no neck-rigidity and Kernig's sign was negative. The tongue was of the strawberry type; teeth, gums and buccal mucosa were healthy but covered with sordes. The fauces were injected but there was no membrane. Cultures from a throat swab gave a growth of hæmolytic streptococci. Nothing abnormal was found in the heart, lungs or abdomen. A single normal vaccination scab was surrounded by a small areola on the left arm. The skin around the scab was otherwise unaffected but large areas of the trunk and limbs were covered with an urticarial rash. On the wrists, ankles and at the back of the neck some patches were studded with small vesicles, 2–4 mm. in diameter, some acuminate, others arranged close together in clusters, giving the impression of lobulation. A few had become pustular. Urine normal. Blood culture negative. Wassermann reaction negative. Blood count: white cells 10,000 per c.mm. (polymorphs 73%, eosinophils 5%, monocytes 5%, lymphocytes 17%); no other abnormality.

On July 7 early papillœdema of both eyes appeared with congestion of retinal veins. His condition was otherwise unchanged. On lumbar puncture clear cerebrospinal fluid was obtained; the pressure could not be estimated. CSF: cells 1 per c.mm.; protein and sugar normal; cultures sterile. A tentative diagnosis of postvaccinal encephalitis was made. Next day the papillœdema was more evident, the right plantar response was extensor and the lower right abdominal reflex absent. There was a slight rigor, temperature 102° F. Lumbar puncture yielded clear fluid at a pressure of 100 mm. of CSF; no abnormal constituents; sugar 0.069% (Maclean). The patient was still very ill, restless and hypersensitive. In view of the records of cases successfully treated with immune serum by Horder (1929) and with immune blood by Heckman (1930) it was decided to adopt this treatment. The donor chosen was of the same blood group as the patient and had been successfully vaccinated three months before. A transfusion of a pint of whole citrated blood was given in the evening by the drip method; it caused no reaction. The patient slept well. Next morning there was a striking improvement, the skin was much less sensitive, the restlessness had gone and he looked happy and comfortable. There was now a bilateral extensor plantar response. From this time the temperature began to fall and all active symptoms of encephalitis quickly disappeared.

On July 13 the ophthalmologist reported: "No change in central fields to white or coloured objects. Peripheral fields full. Œdema of nerve heads more pronounced. Marked engorgement of veins. Patient can still read small print with each eye. This suggests an increase of intracranial pressure rather than true optic neuritis." On lumbar puncture the CSF pressure was 90 mm. and the fluid normal.

By July 17 the papillœdema in both eyes was beginning to subside. There was some neuroglial infiltration on the left nerve head. The patient experienced some transient difficulty in micturition during the next few days but his further progress was otherwise uneventful.

The rash.—On admission the vesicular lesions were painted with ichthyol in collodion. They dried up in a few days and the remaining urticarial lesions faded without desquamation, but on July 16 large white areas flush with the surrounding skin, and giving off a strong, sweet smell suggestive of a proteolytic infection, appeared on the hands, wrists, feet and ankles. The temperature rose to 101° F. On removing the dead skin there was a scanty serous exudate containing a few pus cells and cocci. Cultures gave a growth of hæmolytic streptococci and coagulase positive staphylococci. Examination of skin scrapings showed no fungi.

Treatment.—The transfusion of immune blood on July 8 has already been described. In view of the streptococcal infection of the throat and tongue and the presence of a number of skin pustules, sulphapyridine was given from July 9 to 12. Total dosage 20 g. At the end of this time these lesions had cleared up. Skin toilet, baths and dressings with gauze soaked in acriflavine lotion sufficed to clear up the infection of the skin of the extremities. Ascorbic acid was given by mouth. Later, massage was given for the leg muscles.

He got up on Aug. 7 and was discharged fit on Aug. 21. Re-examined on Oct. 15, he was mentally and physically well, and the ocular signs had almost disappeared.

DISCUSSION

In considering the effect of the transfusion, it is necessary to bear in mind that postvaccinal encephalitis commonly runs a stormy course with an abrupt remission in non-fatal cases; the improvement which immediately followed the transfusion may have been due to non-specific factors, but whatever the explanation the change was certainly dramatic. Flexner (1930), in a review of published work, failed to find any recorded cases of generalised vaccinia complicating postvaccinal encephalitis. In the reports on vaccination of the Rolleston committee (1930), 25 fatal cases of postvaccinal encephalitis were described. One (case 114), a boy of 11 years, developed encephalitis on the eleventh day and a papulovesicular rash on the trunk and limbs on the sixteenth day. A case occurring in an infant of 5 months was reported in France (de Lille 1940). Weichsel (1931) described the simultaneous appearance of encephalitis and a general rash on the nineteenth day in a patient aged 17 months. In the later stages white areas appeared flush with the surrounding skin. These lesions were apparently very similar to those found in the present case. Weichsel attributed the condition to "the lively production of antibodies in the skin and cerebral tissues simultaneously." I have been unable to find any record of other examples.

Though postvaccinal encephalitis is commonest at school age, adult cases undoubtedly occur, and some have been reported in this country. In my case the incubation period of thirty days is unusually long. Some of the authorities quoted (Flexner and Rolleston committee) agreed that this period was commonly about 11–12 days, but Flexner noted that there have been cases where it was between 19 and 34 days, this being true of 3 out of 87 English cases and 4 out of 123 Dutch cases. Donnally (1931) reported 2 (of 5) cases which occurred in the fourth week after vaccination. In most of such instances the patient has been an infant. This type of encephalitis has been recognised in association with measles and other exanthemata but never with streptococcal infection,

SUMMARY OF 14 CASES ADMITTED TO HOSPITAL AS POSTVACCINAL ENCEPHALITIS

Case	Date of admission in 1942	Age (yr)	Sex	Previous vaccination history	Recent vaccination history		Days between vaccination and onset of symptoms	Local vaccination response	Main clinical features on admission	Final diagnosis	Result and remarks
					Date	Lymph					
1	July 10	6	M	—	June 25 ,, 28	GLE	10	Normal	Semi comatose extremely irritable	Postvacc enceph	Recovered
2	,, 14	16	M	—	July 5	GLE	6	Severe	Drowsiness, spasticity of lower limbs	Postvacc enceph	Recovered
3	,, 15	41	F	Infancy +	,, 3	GLE	8	Normal	Deep coma	Postvacc enceph	Recovered
4	,, 16	10	F	—	,, 2	Evans	12	Normal	Drowsiness bilateral paresis of lower limb	Postvacc enceph	Recovered
5	,, 16	5	M	—	,, 1	GLE	14	Normal	Deep coma	Postvacc enceph	Died Diagnosis corroborated at autopsy
6	,, 26	2	M	—	,, 5* ,, 12	Jenner s	12	Normal	Deep coma	Postvacc *enceph*	Died Diagnosis corro*borated at autopsy*
7	Aug 4	16	M	—	9		14	Normal	Retention of urine, signs of transverse myelitis in thoracic region	Postvacc enceph	Recovered
8	July 10	4	M	—	, 3	GLE	7	Normal	Convulsions	Epilepsy	Recovered History of fits when aged 1½ and 2 years
9	, 10	39	M	Infancy +	, 4	Jenner s	12	Severe	Semi comatose paralysis of lower limbs	Cerebral thrombosis	Died Diagnosis on histological examination
10	,, 18	29	F	—	, 9	GLE	1	Severe	Severe frontal headache	Postvacc systemic reaction	Recovered
11	, 20	47	M	—	, 8		7	Severe	Severe occipital headache	Postvacc systemic reaction	Recovered
12	,, 21	33	F	Infancy + and 12 yr +	11	Evans	3	Normal	Convulsions	Hystero epilepsy	Recovered History elicited definite neurotic background
13	, 28	19	M	—	,, 1	GLE	16	Normal	Slight drowsiness	Post vacc systemic reaction	Recovered
14	,, 15	10 wks	M	—	,, 5	Lister Inst	6	Very severe	Dead on admission	c Staph septicæmia	Died Staphylococcus (coagulase + and hæmolytic) from heart blood and spleen

* Did not take GLE = Government Lymph Establishment

to 1 330 000 according to the reports of different observers. The incidence in Glasgow (about 1 70,000) is a little lower than that reported (1 48,000) for England (Committee on Vaccination, 1928) No comment can yet be made regarding age, sex and previous vaccinal history, for the relative figures for the vaccinated population are not yet available Case 3, which recovered from deep coma, was well vaccinated in infancy

Source of lymph —The greatest proportion of persons were vaccinated with lymph from the Government Lymph Establishment The cases were not associated with any particular batch or source of lymph, which conforms with previous experience

Time of onset after vaccination —The cases all occurred within 6–14 days of vaccination, one on each of the 6th, 8th, and 10th days, two on the 12th and two on the 14th day Armstrong (1932) reports that the commonest latent period after vaccination is 10–13 days in Thompson's (1931) collected series, 82% of the cases occurred within 7–14 days of vaccination

Clinical features —In the 3 most severe cases (3, 5 and 6) deep coma was the outstanding feature, in these the clinical picture on admission was essentially similar and prognosis, on ordinary medical indications, seemed very bad Cases 5 and 6, however, were the only two who received an anti-vaccinal horse serum kindly supplied by the Lister Institute In case 5 its administration was without effect, in case 6, which also received much additional therapy, the coma appeared to lighten considerably for about 24 hours In both cases serum was *not* used as a last resort The recovery of case 3, quite unexpected in view of the apparent severity on admission, *would lead us to be very disinclined* to hazard a prognosis in any severe case, and, therefore, to place any stress on an isolated recovery after the use of a particular treatment In case 7 the lesion seemed to be confined to the spinal cord There was a definite and typical transverse myelitis X-ray examination of the spinal column revealed no abnormality This case is very similar to those previously reported by Peake (1929) and Brockbank (1931)

In contrast to the apparent severity at the onset recovery, when it occurred, seemed complete We have seen all the cases since dismissal and no sequelæ have been noted

Other cases —In 3 of the other cases the condition was merely a severe general reaction to vaccination In 2, epilepsy was the correct diagnosis—in one, there was a definite history of fits in earlier life, in the other, the patient was of an emotional type and vaccination had merely acted as a "release" In case 9, the diagnosis rested on microscopic examination of brain tissue The exact ætiology of this lesion was not clear, although the relationship with vaccination seemed suggestive Case 14 is, so far as we know, the only case in which death was the result of infection

SUMMARY

About 500,000 persons were vaccinated in Glasgow during July There were 7 cases of postvaccinal encephalomyelitis, of which 2 died, 6 of the 7 cases were in persons over five years of age vaccinated for the first time Two other deaths occurred in connexion with the vaccination campaign, one from cerebral thrombosis and one from septicæmia

THE LANCET

LONDON. SATURDAY, DECEMBER 5, 1942

PROSPECTS IN THE NEXT INFLUENZA PANDEMIC

WILL this war, like the last, bring in its train a pandemic more lethal than the war itself ? Does the work of the last decade on influenza viruses put us in a better position to control a pandemic if one should arise ? Is not this the time to look ahead and plan a programme of research and attempted control ? These are the questions which BURNET and CLARK[1] ask in a stimulating monograph published in Australia In this they summarise the knowledge gained since 1933 about influenza A virus its behaviour in laboratory animals and its relation to disease in man, and set down the comparatively little that is known about the serologically distinct influenza B virus Next, they try to interpret the epidemiological and other features of the 1918-19 pandemic in terms of the knowledge since gained about influenza viruses We do not, of course, know whether the cause of the pandemic was virus A or B, or something else, though it probably differed antigenically from the agent causing influenza in the pre-pandemic years BURNET and CLARK think it may have differed also in some other biological property, perhaps in the speed with which it could spread over and infect the respiratory tract

Their survey of existing knowledge leads on to a discussion of prevention and control Land quarantine is impracticable The quarantine imposed at ports apparently kept Australia free from the pandemic disease until January, 1919, though immunisation by the "ordinary" influenza, which prevailed in Australia in the autumn of 1918, may have contributed to that result If the quarantine measures were as effective as appears, one would have to believe that infection was spread only by persons with active and overt disease There is some evidence that this is not the case as regards the epidemic influenza prevalent more recently Subcutaneous vaccination against influenza virus A can certainly increase neutralising antibodies in man , the latest vaccines have reduced the incidence of infection in some trials[2] but not in others[3] There is apparently a closer correlation between antibody level and immunity in the experimentally produced infections of man than in naturally contracted influenza, BURNET and CLARK see here a clue worth further pursuit There has lately been a highly successful trial of vaccine where the test was a deliberate infection of human volunteers[4] This result contrasts with the much less dramatic outcome of field trials of vaccines Altogether there seems little justification for building up large stocks of virus-A vaccine at present, particularly as the antigenic nature of pandemic virus is unknown But when a pandemic has once begun, large-scale production of the appropriate formolised vaccine can scarcely be developed in time or on anything like the requisite scale The Australian workers are therefore attracted by the idea of developing an attenuated strain which, given intranasally in the living state, might lead to a subclinical infection which would produce immunity to the serious form of the disease Relatively small quantities of such a living vaccine would be needed A trial by BURNET[5] with influenza B virus encourages such hopes , virus adapted to the chick embryo and given intranasally to 22 volunteers produced trivial symptoms or none, and yet caused a substantial rise in antibodies in persons in whom these were initially low Unfortunately BURNET's earlier attempts to achieve a similar result with influenza A virus—probably the more important pathogen—were much less successful He suggests that, if the next pandemic follows precedent in coming in several waves, an attenuated strain might be developed from virus isolated in the first wave in time for it to be used for immunising against later waves In 1918, however, an actual attack of influenza in the first wave was no guarantee of immunity in subsequent waves

There are two other possible weapons of defence Success has been achieved in protecting mice against influenza infection by local passive immunisation of the respiratory tract with atomised immune serum[6] SMORODINTZEW and his colleagues[7] in Moscow have used this method in human volunteers An apparatus was constructed from which 15 people at a time could inhale atomised anti-influenzal horse serum through masks A 90% reduction in the incidence of influenza is claimed, though we are not told what were the criteria used for the diagnosis of influenza in the treated or control groups Such a method has the advantage over vaccines that it could be used early in a pandemic—as soon as convalescent sera from the first victims were available In America the antiseptic vapour of propylene glycol is being intensively studied, especially by ROBERTSON and his colleagues[8] STOKES and HENLE[4] report that both propylene glycol and ultraviolet irradiation had an astounding effect in saving the lives of mice exposed in an empty ward to mists of atomised influenza virus which killed 100% of control mice, and HARRIS[9] has had encouraging results in reducing respiratory infection in this way in a convalescent home for children Propylene glycol, even in the rather high concentrations needed, is said to be non-toxic for man, but to be effective much larger quantities have to be put into the air than is the case with hexylresorcinol, resorcinol or hypochlorites There is almost certainly a big future for antiseptic aerosols, but it is hard to prophesy which will be the most useful

BURNET and CLARK admit that recent additions to our knowledge of viruses may not suffice to permit control of a new pandemic , but, very rightly, they urge that we must at least be ready to study it intensively when it comes, to learn all we can of its genesis and perhaps place ourselves in a position to prevent the next pandemic but one Meanwhile, remembering though Horder suggested that concurrent infection may be an exciting factor in some vaccinal cases. It is possible that the oral streptococcal infection which preceded the onset of the acute symptoms in the present case may have had such an effect.

After summarising the various theories as to the causation of the encephalitis, Flexner concluded that the ætiology was still unsolved. More recently, Finley (1938) made out a case for the allergic theory. He pointed out that the local skin lesion was regarded as an allergic immunity reaction and that it was at its acme about 12 days after vaccination, which was at the same time as the incidence of encephalitis and of generalised vaccinia. He argued that experimental evidence proved cerebral tissue to be immune to the virus after vaccination just as the skin was, so that it could be assumed that the specific allergic state of the body following vaccination influenced the CNS as well as the skin and other tissues. If this view be accepted, there seems to be no reason why such a reaction should not occasionally result in simultaneous encephalitis and generalised vaccinia.

I wish to thank Colonel A McKie Reid for his advice and permission to publish this report, and Major J Macaskill and Lieutenant J N Morris for their help in the management of the case.

Reviews of Books

War Against Disease

MILTON SILVERMAN London Michael Joseph Pp 284 12*s* 6*d*

NOT so long ago the study of history meant the memorising of dates and dynasties, but there is now a wider appreciation that the history of dress or the story of the evolution of the internal combustion engine possess more human interest than the battle of Crecy or the avarice of Henry IV. The history of drugs, too, has its news value. Their discovery and use in therapy have been bound up with the joys and sorrows of mankind, and often drug-hunters have found themselves enjoying curious or droll experiences. The cause of materia medica has now been championed by Mr Silverman, who tells how we came to possess our important drugs—morphine, quinine, digitalis, aspirin and many others. His presentation of the subject is frankly dramatic, and he draws on his imagination for dialogue. His pawky humour, reminiscent of an American talkie compère, enlivens his subject. The painstaking observations of William Withering on foxglove are engrossing; we seem to stand beside the gallant Ehrlich as he battles with new enemy hosts, or by Fourneau, unravelling the tangled skein of Bayer 205. Here and there Mr Silverman has undoubtedly overstated the case: the curing of the Countess of Cinchon makes a good story but it has long been exploded, and the remark "... the very obstetrician who had delivered the great Samuel Johnson," credits that infant purist with a versatility which he would have hastened to repudiate.

Man in Evolution

G DE PURUCKER Point Loma, California Theosophical University Press Pp 389 $2.50

IT is impossible to raise any enthusiasm among scientific men by asserting that one has an intuitive belief that the earth is flat, but there are subjects upon which orthodox science still speaks with a divided voice, and upon such questions there may still be scope for the play of pure thought detached from hard-and-fast experimental methods. Those who subscribe to the system of thought underlying theosophy—upon which this volume is based—hold that many of the postulates inherent in their beliefs have been made in opposition to the scientific dicta of the time and have subsequently been proved to be correct. Some may urge that luck has been on t side and that what were at the time no more than ha guesses have ultimately proved capable of verification scientific methods. After all, a close approximation to the modern atomic theory was current about 400 BC, the doctrine of the circulation of the blood was anticipated by Chinese philosophers some two thousand years before the time of Harvey, and the conception of evolution itself may be traced back to the dawn period of philosophic concepts. The thesis put forward in this book is that man is an extremely ancient—even if not the ancestral—form of life. This is apparently no new creed to theosophists, for it has been a fundamental part of the doctrine since its first inception. Even here parallels may be found in the dicta of those who have approached the subject from other standpoints; more than thirty years have passed since Enrico Marconi enunciated his theory of involution, as opposed to evolution, and claimed to have established scientific proof for his thesis. Professor Sergi dealt severely with Marconi's claims and so far as the orthodox scientific world is concerned they appear to have passed into oblivion; they seem also to have escaped the notice of those whose views they so strangely support. Yet, even with Marconi swept aside, it must be admitted that changing modes of thought have left orthodox ideas on the antiquity of man and of his relationship with the rest of the primates more plastic. Even the die-hards of the immediate Darwinian inheritance admit that man may be a more ancient and a more primitive form than was at one time thought possible. The book gives the orthodox scientist with an open mind a chance to learn the opinions of those who do not follow the experimental method.

Handbook of Ocular Therapeutics

(3rd ed.) STANFORD R GIFFORD, MD, FACS, professor of ophthalmology, North Western University Medical School, Chicago London Henry Kimpton Pp 410 20*s*

THE four years since the last edition of this book have been, as Dr Gifford remarks, the most exciting within the recollection of most of those interested in therapeutics. The use of sulphapyridine in gonococcal ophthalmia and of riboflavin in corneal vascularisation are among the many modern treatments described, and in all that relates to non-operative measures the text is up to the minute. Most of the minor surgical procedures are well dealt with, and the section on recurrent corneal erosion is described in unusual detail. Diathermy for detached retina is touched on, but so little is said that it would perhaps have been better to have omitted it entirely. The list of ophthalmic drugs in common use is especially helpful. The book is refreshingly frank; the author does not hesitate to label a drug as useless where he has found it so.

War Gases and Foodstuffs, Chemical Warfare and Food Supplies

W R WOOLDRIDGE, PhD, MRCVS London Leonard Hill Pp 50 2*s* 6*d*

EXCEPT for some alleged use by the Japanese against China, gas attacks have so far not figured in the present war. There is no guarantee that they will not do so and this country has been foremost in guarding and training its citizens against such a possibility. Since the danger of such attacks is not confined to injuries against which masks and protective clothing offer sufficient defence, we may welcome a work of this kind published at a price which the most parsimonious local authority will hardly begrudge. Foods not stored in air-tight containers may take up almost any war gas from the air around them and might easily be contaminated by contact with liquid "gas." The author notes that decontamination is not particularly difficult, but for the sake of attractiveness and nutritive value prevention is better. He discusses protective storage of foods while being unshipped, in transit and when in storage, as well as the allied problems of protecting farm animals and their foods, on which he is specially qualified to speak. It is almost impossible, he says, to render water-supplies dangerous by gas. The organisation of the contaminated-food service is described and the information should be of value to local authorities; a table at the end shows the effect of war gases on animals with hints for treatment.

MYASTHENIA GRAVIS AND THE THYMUS

The thymus gland, or θύμος, was so named by Galen in the second century A D from its likeness to a bunch of thyme-flowers From the time of Galen, who supposed that it was placed in the mediastinum to protect the vena cava from the pressure of the sternum, to that of latter-day coroners, who have used it in the investigation of death under anæsthesia to protect the reputation of the medical profession, it has remained an enigma Endocrinologists have wooed it in vain Physiologists and pathologists have drawn away from it baffled Not even the anatomists or the histologists have spoken of it with their customary precision, for we are still uncertain whether it has any real existence in the normal adult, and whether the main cells of its medulla are to be regarded as epithelial or endothelial

A mystery of another kind is hidden under the name myasthenia gravis, a disease which is uncommon but none the less notorious for its resistance to both rational explanation and treatment In its earlier stages it is subject to spontaneous remissions, sometimes of long duration, and in recent years its victims have been greatly helped by the work of Dr Mary Walker, who established the value of prostigmin in temporarily alleviating the symptoms Yet in general it has been regarded as more or less hopeless, and many a sufferer has lingered miserably in its clutches only to die in one of the respiratory crises which characterise its later stages From a discussion at the Neurological Section of the Royal Society of Medicine on Nov 19 on myasthenia gravis and thymectomy it seems that this conjunction of two mysteries may result in a real increase of knowledge about both of them The treatment of myasthenia by removal of the thymus gland is not, as one speaker in the discussion averred, an entirely empirical procedure, for it has been known for some years that a certain proportion of thymic tumours are associated with myasthenia gravis and removal of the tumour has occasionally resulted in improvement, or even cure, of the disease Not many patients with myasthenia, however, could be shown to have a tumour in the mediastinum, and it was therefore a logical step to remove the thymus gland itself, which was often enlarged in this disease Blalock and his associates[1] in Baltimore reported last year that they had performed a thymectomy in 6 patients with myasthenia gravis, and had obtained in 3 of them improvement almost amounting to complete remission, there was one death At the RSM James Carson and Geoffrey Keynes reported on the surgical treatment of 12 patients, apparently the longest consecutive series yet recorded Most of these patients had been under observation at the National Hospital, Queen Square, and had been operated on at the LCC Hospital, New End, Hampstead, the first operation having been done in February of this year All the patients had been chosen as presenting the fullest possible picture of the disease and all had responded satisfactorily to prostigmin In addition, most of them had given a positive response to the intra-arterial injection of prostigmin, a delicate clinical test recommended by Blalock in order to clinch the diagnosis Exposure of the mediastinum by splitting the sternum under completely controlled anæsthesia revealed in every case an enlarged thymus gland, a bilobed structure varying in weight from 7 5 to 31 g In 2 there was also a small thymic tumour not demonstrable by radiography Three of the patients died, one from collapse of the lower lobes of the lungs, one from failure of hæmostasis, and one in delirium tremens Of the remaining 9, 3 had experienced complete remission of the disease and had required no prostigmin for periods up to nine months, 4 had greatly improved and could subsist on a much reduced dose of prostigmin, and 2 had not shown any material improvement, though one of these had a considerable overlay of neurosis which obscured the picture Carson said that spontaneous remissions usually occurred only in the early stages of the disease, the symptoms becoming fixed as they progressed The truth of this was demonstrated by the histories of the 12 patients reported on Keynes stressed the fact that all the patients were extremely ill, so that " the maximum hazards had been challenged," the postoperative course in most of them being very stormy and difficult to manage Their management had been in the hands of J E Piercy, surgeon at New End Hospital In addition 3 of the patients had exhibited signs of thyrotoxicosis, one to such a severe degree that a hazardous subtotal thyroidectomy had to be done before thymectomy could be contemplated six weeks later It is interesting, in view of claims made elsewhere[2] to have cured myasthenia gravis by thyroidectomy, that this patient's myasthenia, already severe, became even worse after the thyroidectomy He is now reported to have greatly improved, all his symptoms being relatively slight and his prostigmin needs much reduced Carson reported that the intra-arterial injection test had become negative in the patients with complete remissions of the disease, and less strongly positive in those that had improved There was apparently no correlation between the size of the thymus and the severity of the disease or the results of the operation It was suggested that undetected extensions of thymic tissue beyond the anatomical confines of the gland might account for the uneven results of the operation The best results had been obtained in the patients who were not only the youngest but also showed the most pronounced symptoms

It is to be hoped that this surgical experiment is only the beginning of a real advance in knowledge and treatment It is tempting to suppose that the neuromuscular defect, known as myasthenia gravis and closely resembling curare poisoning in its clinical features, may be due to an internal secretion elaborated by a hypertrophied thymus, though both the speakers avoided any rash pronouncements on the pathology of the glands that have been removed The specimens are in process of investigation In the discussion Russell Brain and R L Galloway announced that they had treated 3 myasthenic patients by thymectomy without result, but the statement by Galloway that none of his patients gave him the slightest anxiety after operation, and by Brain that one of them showed only the bulbar signs of the that it was the bacterial secondary infections which killed most of the 1918–19 victims, let us thank Heaven for sulphonamides

FITNESS CENTRES

WAR, by its calls on the nation's man-power, makes it necessary to replace and supplement ordinary sources of labour, and invests fitness for work with a new importance The disabled man becomes a potential asset Britain has lagged far behind Denmark in finding suitable work for the disabled citizen In 1936–37 in Scotland an insured population of 1 8 million lost 26 million working days on account of illness, and 42% of the time lost was accounted for by illnesses current throughout the whole length of the year The chief contributors to this long-term incapacity were mental and nervous disease, rheumatism, and diseases of respiratory and circulatory systems Many of these cases were long past any hope of reabsorption into industry In 1937–39 an attempt was made in Scotland to tackle this problem by reviewing the illnesses of insured persons as soon as they had lasted three months, to see whether anything could be done to preserve the patient's capacity for work Doubtless the only hope of salvation for many lay in a change of employment, but there was no formal linkage between the central authorities responsible for health and labour In 1935 a British Medical Association committee reported on the undue delay in securing the return to employment of injured workpeople, and in 1938 the Delevingne Committee produced its report on rehabilitation—a report recognising the need for continuity of treatment right up to the time of return to work, but this body was essentially surgical (and mainly "fracture") in its outlook About this time colliery owners in the Midlands were planning measures for the return to working capacity of injured miners, and the rehabilitation centre at Berry Hill Hall in particular has attained a notable measure of success in returning patients to full employment in the pits

The war brought new problems, the Army and the Royal Air Force have their own rehabilitation centres, not always so called, no-one seems to have called them "fitness centres," which seems an obvious name Thousands of patients have been invalided out of the Services, and here again, as in civil life, the disability has more often been medical than surgical Left to themselves these men and women do not do well on their return to civil life, either medically or in work In the autumn of 1941 the Ministry of Labour introduced an interim scheme for the resettlement, and if necessary training, of these ex-Service patients and of patients leaving civilian hospitals with residual disabilities It would be valuable to learn how many cases have been dealt with under the scheme, and in particular how many patients were followed up on their return to civil life and with what results Follow-up is the acid test how many of those placed in employment have held that employment? Early in 1942 the Department of Health for Scotland inaugurated the Clyde Basin experiment Doctors of the area were invited to refer for overhaul (including, where necessary, hospital and convalescent-home care) young people between 15 and 25 who were reacting unfavourably to industrial stress Until recently the scheme did not ensure a change of work where that was necessary in the interests of but the Chief Medical Officer says that the linkage is now being made The recently published white paper on coal contemplates the development of rehabilitative measures, doubtless with a view to the increase of coal output, other trades are interested and it will be surprising if there is not soon a demand for fitness centres for war workers generally Rehabilitation is one of the best examples of social medicine To be successful it must be a three fold conception, aiming at the provision of medical and surgical skill of the highest quality, organised to secure the patient's physical recovery, the preservation and development of those qualities of initiative and "will to recover" found in nearly all patients at the start of illness but so often lost during treatment, and the establishment of a close linkage with the social and industrial background to which the patient is to return after treatment These aims carry certain implications that the medical men participating in the work must be enthusiasts, able to inspire and hold the confidence of their patients, that, while it may be advantageous to secure geographical separation between fitness centre and hospital, medical supervision must be continuous throughout the reconditioning period, so that, for example, the same surgical skill is applied to attaining full movement in the knee as to setting the original fracture, and that the necessary liaison with industry must be not merely with the branch of industry from which the patient was drawn but with the Ministry of Labour—for even in the happiest circumstances some cases will have residual disability which precludes return to old employment, and rehabilitation is useless if it discharges patients to idleness

It seems inconceivable now that we should revert after the war to a system that left the disabled man derelict and demoralised to eke out his miserable years on public assistance But in peace the demand for labour will be less urgent, and without a planned policy the cardiac cripple and the limbless man will again be left to official or unofficial charity, a result economically wrong as well as unsocial, for many of these men can do useful work In times of depression a disabled man cannot hope to hold a job except on merit, he must be able to do his particular job as well as the average man That means that work must be selected to suit his disability, but it must also be work in which he is really interested, and he must be trained until he is efficient at it It is important to ascertain the degree of disability early, to study sympathetically the needs of each case, and to meet those needs so far as practicable Rehabilitation has enormous possibilities, it must bridge the gap between the health services and industry and living conditions which has stultified medical care for years Far too many patients have been discharged from hospital as improved, only to return to conditions of life and work that must inevitably produce a relapse The reconditioning process must be planned It should be associated with hospital care and with general practice, possibly through a regional medical service It should not be confined to particular occupational groups, to particular age-groups, or to particular diseases It will be difficult work, but as SIR WILSON JAMESON says, prevention is coming *to have, even in* the public mind, something of the drama of cure natured tolerance to thinly veiled contempt, regard physical medicine as a convenient refuge for the disposal of rebellious and troublesome sufferers from chronic rheumatism Physiotherapy in their eyes is indebted for its bare existence to the orthopædist, phototherapy is dependent for maintenance upon the dermatologist, electrotherapy is parasitic upon the X-ray department And even within their own ranks, Mr Bauwens finds, physiotherapists have not been without their doubts and difficulties Called upon for a definition they have been unable to agree in what way and to what extent the scope of physical medicine should be isolated and its future defined Yet there is no branch of medicine or surgery where physical methods, either diagnostic or therapeutic, have not some application, even if at present rather vaguely comprehended they should have a part in the management of diseases and injuries and in the maintenance of health He would like to see the medical student instructed in physical medicine at least sufficiently to recognise its opportunities and to make proper use of them A separate qualification is essential, he feels, to place the specialty in its proper relation to the profession as a whole and to attract the younger men into its practice A diploma would ensure uniform teaching and guarantee proficiency A committee should be formed, he thinks, of informed practitioners of physical medicine to plan for this and other advances To encourage research in the specialty this committee should later be replaced by a Faculty of Physical Medicine, and a fellowship of the faculty would be instituted as a higher qualification This parent body would probably give birth to a chair of physical medicine but he would not hazard a guess at this gestation period In the subsequent discussion the idea of a diploma found general favour, though some speakers felt it should not be established until men now with the Forces would be in a position to take it

HIGH VOLTAGE X RAYS

At a meeting of the American Röntgen Ray Society, briefly reported in *Science* for Sept 25 (supplement, p 8), Richard Dresser and John Trump described the treatment of cancer by means of a very high voltage X ray generator, now being used experimentally at the Massachusetts Institute of Technology The electrostatic generator employed is evidently a development of the Van de Graff generator first installed there The working principle of this machine takes us right back to the days of the friction and influence machines of electrostatic fame, and once the first surprise has gone it seems an obvious step to use such methods when the chief requirement is the building up of a really high potential gradient without concern for the fact that the resulting current through the X-ray tube is going to be a mere trickle At the Massachusetts Institute they have succeeded in building a reliable machine on the basis of friction and induction and it works at 3 million volts The electrons speeded by such a potential difference on impact with the anti-cathode give X rays of shorter wave length than the gamma rays from radium By their use a bigger percentage depth dose can be given to the body, this reduces the dose that the skin and overlying tissues have to bear, and on this score is an advance in technique Time will show whether there is benefit from its use in cancer If it should prove that X rays at 1, 2 or 3 million volts really do mean an all-round technical advance in the treatment of malignant disease, then a big economic question will arise Is this country going to provide the money needed to instal and maintain such machines? Lately Osgood and his colleagues[1] of Portland, Oregon, and Berkeley, California have exposed cultures of human marrow to high voltage X rays and to neutrons The effects were compared quantitatively with those produced by 200 kV X rays and by beta rays from radioactive phosphorus They maintain that the major action of these various forms of ionising radiation is to inhibit the onset of mitotic and amitotic division of the cells, they were unable to show any specific wave-length action on the medium they used, and conclude that if there is any advantage in the use of million-volt Röntgen rays it would have to arise from a superiority of depth dosage or a decrease of skin damage

PLANNING FOR HOLIDAYS

Leisure is strictly rationed during the war, yet even in average prewar years only about a third of our population were accustomed, or could afford, to take as much as a week's holiday away from home The Holidays with Pay Act of 1938, must be given its full scope after the war, but as a PEP broadsheet, *Planning for Holidays*, points out, adequate facilities for holidays must also be provided The twin problems are transport and accommodation Railways in 1937 carried twice as many holiday passengers in both July and August as in May, June or September, and rooms at holiday resorts were correspondingly overcrowded Staggering of holidays in industry and schools could reduce the peak cost of accommodation, and improve the amenities at the resorts by spreading the load Increased use of camps and hostels, especially non-commercial ones, will be needed for what may well be a stampede of holiday-starved crowds at the end of the war Holiday facilities might well be developed on a planned basis and a national scale The growth of mushroom holiday towns, straggling and featureless, must be restrained by the control of land development, for these islands are none too large for our considerable population More national parks are wanted, and some of the country mansions of the erstwhile rich, now being used by military and civil authorities, might at the end of the war be developed by the state as people's holiday centres PEP suggests a survey of all holiday quarters and the provision by a National Holiday Centre Corporation of basic holiday accommodation at a price within reach of all wage-earners

GRANULES IN PUS CELLS

Every student must have been fascinated by the purposeful air of the living polymorphonuclear leucocyte seen in living preparations on a warm stage, projecting cytoplasmic processes, it elbows its way through the red cells, humping its nucleus along like a pack These cytoplasmic projections, like the rest of the cell, are filled with refractile granules in a constant state of turbulent dancing activity In early days this motility of the granules was put down to Brownian movement, but Hope Simpson[1] reminds us that this is hardly an adequate explanation He finds pus cells easier to study than blood leucocytes and the best material for his purpose is obtained from thin sero-pus or purulent urine In fresh unstained preparations the pus cell is spherical, with its lobed nucleus squeezed together near the centre of the cell, the cytoplasm is packed with violently turbulent granules The granules can be seen to press on the outer cell boundary to form the tip of a slender cytoplasmic process which then shows rapid, violent, lashing movements, the whole cell may become covered with a wavy coat of such processes and several may join together to form thick strands Other pus cells, such as from sputum in acute catarrhs, have nuclei with lobes spread out and relatively few granules in the cytoplasm, some quite motionless In such fresh preparations the cells live about 3 days, the manner of their death is characteristic The nucleus becomes peripherally placed, the granules collect in a cluster around it and become motionless, often a few granules remain still ranging over the now empty expanse of cytoplasm and then "one by one creep silently to rest," joining the cluster round the disease, give rise to doubts whether these cases were at all comparable with those of **Carson** and **Keynes** None of **Brain**'s patients had been tested by intra-arterial injection and they seem to have been mildly rather than seriously ill and elderly rather than young **Dickson Wright** had performed the operation 4 times, with a remission in one case This successful operation had been done through an incision in the neck, a method which **Keynes** had previously condemned as dangerous and unpractical The second operation had been unsuccessful and the other 2 were too recent for an opinion to be formed **Gordon Holmes** spoke of the effects of X-ray therapy on myasthenia gravis, admitting that good results were relatively few and that he felt no enthusiasm for the method **L A E Laurent** cited 4 patients treated by X rays, of whom 2 were now very well and the others improved **Piercy** mentioned that one of the New End patients had been previously treated with X rays which had made her definitely worse All the speakers referred to the not infrequent association between myasthenia gravis and thyrotoxicosis, and **Brain** in particular stressed the confusion that may arise between myasthenia gravis and thyrotoxic myopathy The fact that the thymus gland is usually much enlarged in primary thyrotoxicosis was not mentioned Perhaps the speakers were wise not to introduce any further side-issues into a subject which already bristled with them

Annotations

A BOOK FOR RUSSIAN COLLEAGUES

The Anglo Soviet Medical Council, formed soon after the Nazi attack on the Soviet Union, has encouraged the flow to this country of Russian medical books and journals, and recently articles on new developments in medicine in the USSR have reached our medical journals via the council To obtain and publish Russian work is, however, only half the task which the council have set themselves, during the last year their team of 35 translators has been occupied in turning into Russian *Reviews of British War Medicine*, written by eminent members of our profession This difficult and highly technical task has now been completed and the book was formally presented by Sir Alfred Webb Johnson, president of the council, to Mme Maisky at a meeting at Gaumont-British Film House on Nov 23 Three thousand copies of vol i of this work, containing 26 articles, are being sent to the Soviet Embassy for dispatch to the USSR Their distribution, it is hoped, will not only be helpful to our Russian colleagues but will further the increasing understanding between them and ourselves Sir Alfred announced that the second volume, which will deal mainly with thoracic surgery, was almost ready for the press Mme Maisky thanked the authors and translators of the book and paid tribute to Dr Elizabeth Bunbury, hon secretary of the council, who had coordinated the translated material and prepared it for press Mr Ivor Montagu spoke on Soviet scientific and educational films as a prelude to the showing of two such films[1]

APPENDICITIS AND GASTRO-ENTERITIS

The patient with symptoms of gastro enteritis who is also tender in the right iliac fossa may raise difficulties, and Quigley and Contratto[2] have studied the records of 100 Harvard undergraduates with gastro-enteritis and 60 with appendicitis confirmed pathologically in the hope of finding some diagnostic pointers to in the diagnosis of such cases Pain is always a minent feature in appendicitis but is rarely s Murray,[3] in the records of 1000 cases, found that began in the right iliac fossa in 10% and shifted t usually from the epigastric or umbilical region, in 90% Quigley and Contratto found that 64% of enteritis cases had colic, while 69% of the appen *patients had steady pain Two-thirds of patients* gastro-enteritis but only a third of those with appen were unable to localise the pain Vomiting was as common in gastro enteritis as in appendicitis (38%) Abdominal tenderness of some degree was present in cases of appendicitis, nearly always in the right lo quadrant Gastro-enteritis caused tenderness in than half the cases, and when present it was more diffuse, being nearly as often above as below the umbilicus Cough pain, and rebound and rectal tenderness, though each present in only 37% of cases of appendicitis, were of great diagnostic significance because they were never found in gastro enteritis Only slight fever was usual in both groups, a temperature of over 101°F was recorded in 9 cases of gastro enteritis but in only 1 of appendicitis American surgeons make more use of leucocyte counts than we do Quigley and Contratto found that the average count in the appendicitis group was 18,300, against 12,400 in gastro enteritis, none of the appendicitis group had a count of less than 10,000, whereas more than a third of the others had Diarrhœa was of course usual in gastro-enteritis, whereas only 4 patients with appendicitis had loose stools and 2 of these had taken cathartics From these early cases in young adults the conclusions reached were that an explosive onset, colicky abdominal pain, vomiting, diarrhœa, high fever, a white cell count of less than 10,000 and bizarre or absent abdominal signs point to gastro enteritis An insidious onset, continuous abdominal pain, and tenderness in the right lower quadrant with true muscular spasm all point to appendicitis, and rebound or cough tenderness referred to this quadrant are almost pathognomonic In the early stages repeated examination will aid the diagnosis and a laparotomy must sometimes be done to be on the safe side "When in doubt operate" is a safe slogan but an unsatisfactory one, for it will mean several weeks off work in some cases which would have recovered in a few days if left to nature and kaolin

THE STATUS OF PHYSICAL MEDICINE

At a time when postbellum planning has assumed epidemic proportions and characteristics it was only to be expected that the practitioners of physical medicine should prove susceptible to the infection Some anxiety in respect to their position in the future was warmly expressed by Mr Philippe Bauwens in his presidential address to the appropriate section of the Royal Society of Medicine In a kind of apologia pro vita sua—it was, he said, his only excursion into medical politics—Mr Bauwens traced the history of his specialty The earlier representations of physiotherapy—balneology, heliotherapy and thalassotherapy—arose spontaneously and as a result of climatic peculiarities in different localities They owe their existence, in fact, to geographical rather than scientific considerations, with the result that monopolies and rivalries have shadowed their exponents with a suspicion of vested interest Actinotherapy and hydrotherapy are also products of natural phenomena, but electrotherapy, having more sophisticated associations, developed as a sort of junior partner of radiology *In time came* massage, remedial exercises, manipulations—and he might have added chiropractics, whose practitioners enjoyed a specialty without systematic teaching or academic recognition The uninstructed, with attitudes ranging from good pasteurisation is impracticable in rural areas because of distribution difficulties In many rural areas abroad—for example throughout Ontario—pasteurisation is enforced, and there seems to be no reason to suppose that compulsory pasteurisation is any less practicable in rural England than in rural Ontario Frazer's pamphlet is so fair and thoughtful that it is unfortunate he should have based his argument on the somewhat unusual conditions in Cumberland He is careful to remark and repeat that he is only dealing with conditions there, but opponents of pasteurisation are not likely to respect that caveat and may try to apply his views to the country generally

FREEDOM FROM WANT

FIRST THOUGHTS ON THE BEVERIDGE REPORT[1]

"Primarily social security means security of income up to a minimum, but the provision of an income should be associated with treatment designed to bring the interruption of earnings to an end as soon as possible"—SIR WILLIAM BEVERIDGE

THE greatest single cause of ill health and sub optimal health, mental and physical, is not a virus or a bacterium but poverty So it is the doctor's duty to fight poverty with even greater vigour than he fights the diphtheria bacillus A complete plan for this campaign has now been placed before us by SIR WILLIAM BEVERIDGE, and if when we have studied it from our special point of view we are satisfied that it is a good plan it will be up to us to support it with all our might The picture Beveridge paints can be studied from two main angles—that of the individual and that of the whole country

Consider the individual Whoever you are so long as you are in work, you will be called on to pay 4*s* 3*d* a week if you are a man, or 3*s* 6*d* to 3*s* 9*d* if you are a woman You will make this payment by buying a stamp from the local Security Office Thus, there is to be a flat rate of contribution for all If you are an employer, you will have to contribute about 3*s* a week for each employee to the security fund Thus, the poll tax on industry which the present insurance schemes embody is to continue In return for your contribution, you will be insured against sickness or accident and unemployment, at the benefit rate of 40*s* a week if married, or 24*s* a week if single or with gainfully occupied spouse You will receive a basic retirement pension at similar rates, at 65 if you are a man or at 60 if a woman, but only if you cease work, if you go on working your pension will go up 1*s* or 2*s* for each extra year you work You will get a marriage grant of up to £10, a maternity grant of £4, and a funeral grant of £20 If you are disabled, you will receive a pension related to your previous earnings, not exceeding £3 a week and not less than your sickness benefit, if the disability is total For each child after the first you will receive 8*s* a week, and if you are drawing benefit for sickness or other reasons you will also get 8*s* a week for your first child If you are a working woman and have a baby you will get 36*s* a week for 13 weeks to make up for your loss of earnings and encourage you to stay away from work as long as is really necessary, if you become a widow, you will get 36*s* a week for 13 weeks, and if you have no children you will be given training in a new job if you need it, if you have children to care for, you will get a guardian's benefit of 24*s* a week at the end of the 13 weeks as well as children's allowances Whoever you are, if you are out of work for more than 26 weeks and there is no job in your old trade, you will be trained for a new one Finally, your contributions will cover medical treatment for you and your family at home, in hospital and at a rehabilitation centre, but when you are in hospital, you will have to pay the 10*s* a week out of your benefit which you would otherwise be spending on food and heat and clothes at home That in outline, is the plan as it affects us all The report deals in detail with every human financial situation that seems likely to arise, and each is carefully provided for It is, in fact, a complete blue print for implementing the fifth clause of the Atlantic Charter in Britain, it offers us for the first time freedom from want

Turning now to the picture as a whole One of Beveridge's prime assumptions is that Britain in future will be free from mass unemployment If a prosperous community shares its purchasing power equitably, there will be plenty for all But in a depression of trade, with real scarcity of the products of labour, no amount of redistribution of wealth will supply the necessities of life to all who need them It was not part of Beveridge's duty to prescribe cures for unemployment, but economic scientists, and even some politicians, know that such cures exist The difficulty lies rather in their application The annual cost of the scheme, working full blast, is some 850 million pounds, or about an eighth of our present national income This is not an unreasonable price to pay About £130 million of this is to come from employers, and £520 million from the Exchequer largely in the form of income-tax Thus, the employer will be called on to pay three times—as an ordinary citizen, as an employer, and as an income-tax payer It may be argued that this is neither fair nor good for industry A simple answer would be to abolish the employer's contribution and increase that from the Exchequer This would combine the benefit of a uniform payment for all with graduated payment (via income-tax) based on capacity to contribute

A fortnight ago we published the interim report of Medical Planning Research That its conclusions should have come so close to Beveridge's is not a coincidence, though it is a tribute to the economic skill of our younger medical planners, the problems examined were the same MPR's benefits were slightly more liberal, but slightly less comprehensive Their total budget was 1050 million, whereas the Beveridge budget is 850 million This difference is accounted for by MPR's inclusion of first children for allowances—an extra cost of 200 million MPR proposed graded contributions for all MPR proposed a social security board, and gave cogent arguments in favour of this form of administrative machine, Beveridge proposes a Ministry, with an additional board to run voluntary industrial insurance, but gives no detailed arguments for his first choice On the purely financial side it seems to matter little, but on the medical administrative side, untouched by Beveridge, doctors may hold strong views On the central aim medical planners will surely feel that they can give Beveridge their full support

MEDICINE AND THE LAW

Punishment under the Scabies Order

RECENT prosecutions at Leeds for offences against the Scabies Order may have useful effect in informing the public of the measures available for checking this very contagious disease The medical officer of health, Dr J Johnstone Jervis, told the magistrate that the Leeds corporation had opened five centres for treating patients Since last June some 1500 cases had been notified, from these notifications more than 4000 other cases had been discovered The Scabies Order was made by the Minister of Health a year ago under Defence Regulation 33A Under its authority a medical officer can inspect premises accommodating verminous persons and can require those persons to submit themselves to medical examination and to present themselves for, and undergo, cleansing and treatment Where the order relates to a child, the parent or guardian must do what is necessary and must comply with any reasonable requirements or instructions In the Leeds cases a man and three women were summoned for failing to attend for examination two of the women were also charged with failing to submit their children for examination Another woman, stated nucleus The normal turbulence of the granules may be ended by exposing them to a cytoplasmic poison like 1% methylene-blue, but then the end comes suddenly when the cell barrier gives way and the stain enters the cell Hope Simpson concludes that Brownian movement cannot explain so patently vital a phenomenon as this granular turbulence , it is something more, he thinks, than a mechanical consequence of the colloidal nature of the cytoplasm, it is in some way an expression of the individual properties of the granulocyte

DIAGNOSIS OF PANCREATIC DISEASE

ACUTE pancreatitis is almost invariably associated with a definite rise in the diastase in blood and urine The test may readily be performed by a simple modification of the Wohlgemuth technique, and the apparatus and technical skill required are hardly more complex than those used in a routine urine examination , if the equipment is always kept at hand the answer may be had within a few minutes But a positive result may also be obtained in cases of cholelithiasis and cholangitis In these conditions, however, there is usually some suggestion of jaundice , so a considerable rise in blood or urine diastase without a rise in the icteric index may be taken to indicate an attack of acute pancreatitis With normal diastase values during the first two days of an acute disease it is fairly safe to rule out acute pancreatitis Loewi's mydriasis test appears to be unreliable The diagnosis of chronic pancreatitis can be confirmed by several laboratory tests It may be associated with fatty stools (traditionally with a low percentage of split fat), microscopic signs of undigested protein in the fæces, abnormal glucose-tolerance curves, sometimes with glycosuria, high blood- and urine diastase values, high blood-lipase, and a deficiency in many of the pancreatic enzymes as obtained through a duodenal tube These tests do not detect the lesser degrees of pancreatic disorder and not one of them is positive in all cases of severe chronic pancreatitis , moreover, with some of them (for example, high fæcal fats and abnormal glucose tolerance) many conditions other than pancreatitis give positive results The secretin test developed in Stockholm by Hammarsten, Agren and Lagerlof is more specific in both acute and chronic pancreatic disease In a recent monograph Lagerlof[1] summarises the Stockholm technique and adds a further series of cases proved by operation or autopsy to be of pancreatic disease After giving an intravenous injection of secretin, the Stockholm workers quantitatively recover all gastric and pancreatic juice for the next 60 minutes through a double tube, the outer section of which opens into the stomach and the inner—30 cm longer—into the duodenum Corrections for regurgitation of duodenal contents into the stomach can thus be made by determining either bicarbonate or bilirubin in the gastric juice The volume, and the bicarbonate, amylase trypsin and lipase content of the juice are also determined In 15 out of 19 cases of acute pancreatitis there was a decrease in the amylase with no decrease in the volume of the juice All cases showed a rise in blood and urine amylase , this test, which should always be performed in suspected cases of pancreatitis is often positive only during the first 2 days of the illness, whereas the secretin test is usually positive during the first 2 weeks In all cases of chronic pancreatitis there was a decrease in the volume, the bicarbonate content or the enzyme content of the juice, or of all three In a simplified test Lagerlof determines only the amylase and bicarbonate, the two most stable constituents Absence of the amylase indicates acute pancreatitis and of bicarbonate chronic pancreatic disease, for the bicarbonate was reduced in 19 of the 23 cases of chronic pancreatitis This was also true for 2 out of 4 cases of cystadenoma and 6 out of 9 cases of carcinoma In 67 healthy persons and 44 cases of disease of the gastro intestinal tract and uncomplicated disease of the gall-bladder and bile du the values for all of the indices of the secretin test normal Abnormal values were, however, found acidosis and dehydration This compares more than favourably with other methods now in use for the diagnosis of pancreatic disease in its milder forms and will doubtless be given further extensive trials when happier days bring supplies of purified secretin and time for duodenal intubation

GOOD CHEER AT CHRISTMAS

" WE are feeling cheered by the recent good war news , may I suggest that we should provide the means of cheerfulness and encouragement for our beneficiaries on Christmas Day " In these words Sir Thomas Barlow prefaces a final appeal for the Christmas Gifts fund of the RMBF More than £1000 is needed to make a gift of £2 to each of those who are dependent on the fund for comfort, warmth or even enjoyment on Christmas Day Contributions should be addressed to the hon treasurer, Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, London, S W 15 and cheques should be made payable to the " Christmas Gifts Fund "

A RURAL M O H CONSIDERS PASTEURISATION

IN a comprehensive report to the Cumberland county council on milk and some of its problems Dr Kenneth Frazer, county MOH, points out that Government policy in recent years has tended to increase the consumption of milk, with priority to certain classes, without any concurrent steps to raise the standard of purity Existing legislation fails to provide either clean or safe milk, and he doubts if any substantial improvement is possible under existing conditions Certainly the figures he submits for Cumberland suggest little progress So far most experts will agree with him, but he takes an unusual view of pasteurisation While admitting that it has no detrimental effect on the nutritional value of milk, and that properly carried out it makes milk safe, he thinks that it cannot offer complete protection because of the opportunities for human error in carrying out the process The need for more fool proof methods of pasteurisation is admitted by all authorities, and they could be achieved He would surely do better to emphasise the need for establishing such methods He does not favour the extended use of pasteurisation in Cumberland, reviving the old argument that pasteurisation is an admission of failure to raise milk to a satisfactory standard of purity Actually the evidence is the other way as Wilson[1] has shown compulsory pasteurisation might be used to raise the standard of cleanliness of milk production throughout the country, rather than to lower it In 1934 the Committee on Cattle Diseases coupled their pasteurisation recommendations with another that all milk, if to be pasteurised or not, should reach a certain standard of cleanliness on the farm Frazer suggests that if higher standards of cleanliness were attained pasteurisation would be unnecessary , but *clean* milk has little to do with *safe* milk—clean milk as readily as dirty can convey the acute infections or the tubercle bacillus LCC figures show that the percentage of tubercle bacilli is, year after year, higher in " accredited milk " (clean milk) than in raw ungraded milk In Cumberland, Frazer points out, there have been few milk-borne epidemics and little non-pulmonary tuberculosis , but he mentions 2 milk borne outbreaks of Sonne dysentery, 2 of sore throat and some cases of undulant fever , and, with 80 notifications of non pulmonary tuberculosis yearly, the bovine proportion is probably not negligible, though he makes no attempt to estimate it But an area may go for years without epidemics, and it would be as culpable to allow the use of a polluted water supply on the ground that no harm had come of it as to perpetuate the sale of unpasteurised milk His last point is that n housing standards in the field covered by the report, ust have been slight That no association was found here between housing and child health does not necesarily imply that there is no such association in other arts of the country

---

[1] Lagerlof, H O *Acta med scand* 1942, suppl 128

[1] Wilson, G S The Pasteurisation of Milk, London, 1942

The infant death-rate in the area in 1930 was 77 per 1000 live births as compared with 58 for England and Wales The rate for all unskilled classes in the country was a little lower than the Durham rate The study shows that in 17,000 births distributed among the families of miners, other manual workers, and black-coated and independent workers, the miners' children had the highest infant mortality This is the nearest approach Mrs Burns makes to a study of economic causes, but unfortunately she does not tell us what proportion of fathers in each group was unemployed or for how long At that time unemployment among men was between 30% and 40% for the whole area and in two districts was over 60% the county (excluding county boroughs) had 50,000 people on domiciliary relief, including 20,000 children It must be borne in mind, too, that many of the younger and hardier men and women, probably those with small families, had left the county in the preceding few years, which would mean that the larger families would predominate in the study , and this and the other reasons given make it difficult to apply the conclusions reached to the country as a whole

THE BIRTH-RATE

She attributes the improvement in the mortality-rates in the last few decades mainly to the declining birth-rate But she is mistaken in suggesting that family limitation has not spread to the unskilled and semi-skilled sections of the populace Innes[7] has shown that unskilled and semi-skilled miners reduced their fertility between 1921 and 1931 to a greater extent than almost any other large occupational group in the community The reduction in the unskilled was by half, in the semi-skilled by 48%, and in mine-owners and skilled men by 28% , by 1931 the fertility of the unskilled men was only slightly higher than that of the mine-owners, a notoriously infertile group And indeed between 1911 and 1931 Durham registered the greatest fall in the gross reproduction rate of any county—by 0 86 as compared with 0 51 for England and Wales Mrs Burns deals rather cursorily with nutrition, but says much of value about the relation of good antenatal, maternity and child welfare care to a low infant and maternal mortality The twice repeated statement that it is more dangerous to be a miner's wife than a miner is not borne out by the Registrar-General's Decennial Supplement But despite these blemishes the study has been made in a courageous and pioneering spirit and brings a great deal of material under review —R M T

PALESTINE

JEWISH VOLUNTEERS

PALESTINE being mandated territory there is no conscription there, but many members of the Jewish population have volunteered for the Army and the ATS Since it was announced that Jewish units would be formed the numbers volunteering have increased, and those of military age who have not joined up are being somewhat coldly treated Every possible help is given to the families of men in the Services , members of the medical association have undertaken to treat them free or for very small fees, and the staff of hospitals have agreed to work ten hours daily without overtime pay in order to release colleagues and keep the hospitals in full action

MEDICINAL HERBS

After several years of experiment, the Agricultural Station in Rechowoth last year began the cultivation of medicinal plants on a commercial scale The scope of the experiment has so far been modest but it promises well Flowers are also grown to make perfumes The medicinal herbs included chamomile, with which 6500 sq m was planted and yielded a crop amounting to 20% of the estimated annual consumption in Palestine , *Datura stramonium*, formerly imported from Europe and now scarce in England as well as Palestine, with which 1000 sq m was planted; hyoscyamus (1000 sq m), peppermint (over 140,000 sq m), *Pimpinella anisum* , fennel and thyme

THE HADASSAH HOSPITAL

In Jerusalem the hospital has opened a new 20-bed typhoid ward for children Similar wards are being set aside for this purpose in other hospitals throughout the country

ACUTE INFECTIOUS MONONUCLEOSIS

Typical cases of glandular fever in adults have been reported in Jerusalem since 1936 Dr E Lyon distinguishes three varieties—tonsillar, pharyngeal and septic —and recommends in severe cases the intravenous injection of convalescent serum, 60–300 c cm , combined with sulphanilamide

HEALTH SECOND FRONT

THE report of the Chief Inspector of Factories for 1941 records a substantial increase in reportable accidents The approximate accident rates per 1000 employed were

	1938	1941	% increase
Male adults	40	50	25
Female adults	9 5	18	90
Male young persons	43	52	21
Female young persons	14 5	18	24

Thus the percentage increase for adult women is by far the biggest, but the rates for females, both adult and younger, are still happily a long way behind those for men These figures lend point to the Communist Party's memo on Britain's health services[1] This is not a plan for the future but a series of proposals for immediate action aimed at stepping up industrial production by reducing loss of time through illness and accident First, attention is drawn to the need for making workpeople think in terms of health No-one who has seen safety devices neglected except when inspectors are around, aisles blocked and lavatories defiled will doubt the need for waking up the workers themselves to their needs The suggestion of a "Workers' Health Inspectorate" has a good democratic touch about it , it would do much to offset the effects of paternalism and stimulate reluctant employers The factory doctor and nurse, and the welfare officer are spoken of as natural allies , if this point of view can be made general the work of these specialists will be greatly helped

Next, the efficiency of the health services is considered The most serious bottle-neck is in the supply of nurses The memo urges the need to utilise the married women who have given up nursing, and to get back to nursing the 5000-odd senior nurses who now give their time to non-nursing duties (home sisters housekeepers, laundry supervisors, &c) But more important still, in the Communist view is the cutting out of all non-essential work This should be done, say, by joint advisory committees of staff and management, analogous to joint production committees in factories, whose members should represent all types of hospital workers Among the subjects worth studying the memo suggests the unnecessary routine ward clerical work (sometimes now done by hand in duplicate), placebos and unnecessary medicines (no four-hourly mixtures unless absolutely essential), and the establishment of a cafeteria system in all staff dining-rooms The joint committee should also consider methods of saving the time of outpatients—itself often a serious industrial loss—as by providing evening clinics It should watch the food of both patients and staff to check overcooking and monotony. Nurses' homes should be run by committees of nurses and not by senior sisters On tuberculosis, industrial medicine, fractures and accidents, and the occupational risks of coal-mining, the Communist Party thinks that reform must come from above, though the impetus may come from below The Government's new tuberculosis plans will meet the case as set out here and the new medical inspectors of mines will also be approved On the question of wages and working conditions, the memo encourages nurses to join a trade-union, and the party's view is that the betterment of the health services is inextricably linked with the building up of the trade-union movement within them , ideally, says the memo, there should be one trade-union for all workers in the health services to be suffering from active scabies, was summoned for failing to attend at the infirmary for treatment The stipendiary magistrate, having obtained from the five defendants (all of whom lived in the same house) an undertaking that they would obey the directions, adjourned the proceedings for a week to see if their promises were carried out If they complied with the requirements, he said, they would each be fined £1 for the previous refusals, if they failed to do so, it would be a serious matter

Some of us are inclined to complain of the multiplication of crimes created by defence regulations and by the orders made thereunder The offences, we protest, are not always conspicuously related to the moral code In the present instance the law and its enforcement have an educative value in inculcating the duty towards one's neighbour

The Typhoid Carrier

If it be an antisocial act to spread disease by neglect of personal cleanliness, there is no obvious moral obliquity in the case of the unconscious carrier That he can create legal as well as medical problems is shown by a civil action for damages arising out of the typhoid epidemic of 1936 In Model Farm Dairies (Bournemouth) Ltd *v* Newman, a case lately noted in the *Solicitors' Journal*, a dairy company sued a farmer for his alleged negligence in supplying milk which was said to contain typhoid germs The farmer sought to protect and indemnify himself by claiming in his turn against X, a third party If the milk on his farm was infected, then, he contended, the infection was caused by drainage from premises occupied by X whereby the stream running through his farm was polluted In the preliminary skirmishes with which the litigation opened, the farmer's legal advisers asked leave to administer an interrogatory to X to compel him to say whether he was not, in 1936, a carrier of the typhoid germ This, said X, was not a fair question, it put him, he suggested, at a disadvantage because he might have to admit something resting on the opinion of an eminent physician who had since died Croom-Johnson, J, before whom the technical propriety of this interrogatory was argued, disallowed the question The Court of Appeal, however, has allowed it to be put Lord Justice Goddard found an analogy in the cases arising over accident and life insurance It is by no means unknown for interrogatories to be administered in those cases asking whether a person suffers (or has at some period suffered) from a particular disease, or even whether his parents suffered from the disease In the case before the court the defendant farmer might be no better off if X answered that he was not, to the best of his knowledge, information and belief, a carrier On the other hand, were the answer in the affirmative, the farmer would be at a real disadvantage if this interrogatory, clearing the ground in advance of the trial, were disallowed

INFANT AND MATERNAL MORTALITY

We are ill-informed about the causes and pattern of reproductive waste, infantile and maternal mortality and stillbirth, and about the total number of deaths directly and indirectly due to maternity, the rate of infant mortality and stillbirths by order of birth and age of mother, the incidence of spontaneous abortions, and the relation of mortality to size and structure in British families Miller [1] has revealed defects in the classification of infant deaths, and the ages of childbearing appear for the first time in the Registrar-General's annual review for 1938, now available [2] Yet without the full facts we are handicapped in planning social services Planners have often had to rely on public-spirited workers to garner new facts and among these must be counted Mrs C M Burns who has published a study [3] of infant and maternal mortality in the County of Durham, based on the records of health visitors for the years 1930–37 She sought information under four heads

1 The influence of the age and parity of a woman on her own chance of survival in childbirth and for five years after the child's chance of survival for five years, the child's chance of death before or during birth, in the first month of postnatal life, between 1 month and a year, and from 1 to 5 years

2 The influence of a high death rate at any stage death rates among the same group of children

3 The influence of the rate of reproduction on the of survival of mother and child

4 The possible effect of such social factors as the occupation, housing and legitimacy on the conclusions from the biological findings

She reviewed 17,049 births in 1930, the history of survivors for the first five years of their lives, and history of previous pregnancies in the families Over two-thirds of the work is concerned with mortality but she nowhere states the number of on which she bases her report Calculating from rates given there were about 2452, of which 656 stillbirths, 1270 infant deaths and 526 deaths the ages of 1 and 5 Another calculation seems to that these figures include 108 deaths of illegitimate dren and 131 of children of multiple births A total 2452 deaths divided into four age-groups (still neonatal deaths, and deaths between 1 and 12 and 1 and 5 years) divided again into birth rank, further subdivided according to maternal age gives very small number of deaths in each group M the influence of illegitimacy and of multiple births incidence of which seems to rise with increasing rank) are difficult to assess There is an abnormally twinning rate in Durham, responsible for 25% of excess stillbirth and infant-mortality rates found over the rate for the whole country These factors the small numbers of deaths reviewed make some of conclusions rather shaky The figures must be accepted with caution as indications rather than as

THE CHILD'S CHANCES

Her findings confirm that too rapid breeding is to mother and child and that very early and very childbearing are associated with a high infant mort These findings, though not new, illustrate how marriage is favoured in one section of society because maximal earnings are attained early, and postponed other sections where the maximal income is not until middle age The lowest death-rates were found among first second and third children born to mothers between the ages of 20 and 35, and fourth and fifth children born to mothers of 35–40 Of children born first children had the lowest death-rates The of stillbirths per 1000 total births were 43 for births, 26 for second, 32 for third and rising to 64 seventh and later births Late children of large families had a high mortality before, during and after birth, and up to 5 years of age At all stages of family, births to older women are more often associated with stillbirths and neonatal deaths than births to young women

Unlike other workers, she finds no association between housing space and child health Hart and Wright [4] in their study of tuberculosis found housing to be important, and the Registrar-General [5] noted a high degree of correlation between mortality and housing even when latitude and social status were constant Stocks [6] showed in his study of child mortality that, at constant density per acre, the death-rate increased step by step with increasing density per room Statistical snags already noted are numerous in this section of Mrs Burns's report, thus the numbers of deaths in each group are not noted, though they must be small, and it is not stated whether illegitimate and multiple births are included The disturbing effects of rent and family income are not studied, nor are the diseases causing death considered The tables combine urban and rural experience but rural overcrowding is in many ways different from overcrowding in towns, besides, after the first month or so the acute infections become important causes of morbidity and mortality and housing conditions probably play some part in their spread Her study deals with a population which according to the Registrar-General is 52% rural and 48% urban (the county boroughs were excluded from the investigation) In 1931 in England and Wales as a whole, only 20% of people lived in rural areas, 34% in urban districts and the remainder in London and the county boroughs At that time Durham was the worst housed county in England and the degree of variation

n housing standards, in the field covered by the report, must have been slight That no association was found there between housing and child health does not necessarily imply that there is no such association in other parts of the country

The infant death-rate in the area in 1930 was 77 per 1000 live births as compared with 58 for England and Wales The rate for all unskilled classes in the country was a little lower than the Durham rate The study shows that in 17,000 births distributed among the families of miners other manual workers and black-coated and independent workers, the miners' children had the highest infant mortality This is the nearest approach Mrs Burns makes to a study of economic causes, but unfortunately she does not tell us what proportion of fathers in each group was unemployed or for how long At that time unemployment among men was between 30% and 40% for the whole area and in two districts was over 60% , the county (excluding county boroughs) had 50,000 people on domiciliary relief, including 20,000 children It must be borne in mind, too, that many of the younger and hardier men and women, probably those with small families, had left the county in the preceding few years, which would mean that the larger families would predominate in the study , and this and the other reasons given make it difficult to apply the conclusions reached to the country as a whole

THE BIRTH-RATE

She attributes the improvement in the mortality-rates in the last few decades mainly to the declining birth-rate But she is mistaken in suggesting that family limitation has not spread to the unskilled and semi-skilled sections of the populace Innes[2] has shown that unskilled and semi-skilled miners reduced their fertility between 1921 and 1931 to a greater extent than almost any other large occupational group in the community The reduction in the unskilled was by half, in the semi-skilled by 48%, and in mine-owners and skilled men by 28% , by 1931 the fertility of the unskilled men was only slightly higher than that of the mine-owners, a notoriously infertile group And indeed between 1911 and 1931 Durham registered the greatest fall in the gross reproduction rate of any county—by 0 86 as compared with 0 51 for England and Wales Mrs Burns deals rather cursorily with nutrition, but says much of value about the relation of good antenatal maternity and child welfare care to a low infant and maternal mortality The twice repeated statement that it is more dangerous to be a miner's wife than a miner is not borne out by the Registrar-General's Decennial Supplement But despite these blemishes the study has been made in a courageous and pioneering spirit and brings a great deal of material under review —R M. T

PALESTINE

JEWISH VOLUNTEERS

PALESTINE being mandated territory there is no conscription there, but many members of the Jewish population have volunteered for the Army and the ATS Since it was announced that Jewish units would be formed the numbers volunteering have increased, and those of military age who have not joined up are being somewhat coldly treated Every possible help is given to the families of men in the Services , members of the medical association have undertaken to treat them free or for very small fees, and the staff of hospitals have agreed to work ten hours daily without overtime pay in order to release colleagues and keep the hospitals in full action

MEDICINAL HERBS

After several years of experiment the Agricultural Station in Rechowoth last year began the cultivation of medicinal plants on a commercial scale The scope of the experiment has so far been modest but it promises well Flowers are also grown to make perfumes The medicinal herbs included chamomile, with which 6500 sq m was planted and yielded a crop amounting to 20% of the estimated annual consumption in Palestine , *Datura stramonium*, formerly imported from Europe and now scarce in England as well as Palestine with which 1000 sq m was planted ; hyoscyamus (1000 sq m), peppermint (over 140,000 sq m), *Pimpinella anisum* , fennel and thyme

In England Now

A Running Commentary by Peripatetic Correspondents

PSYCHOGENIC asthma is a very odd thing I know mine was psychogenic because I could always beat it by a crude bit of psycho applied before the attack During the attack the only thing to do was to read a book in a position of orthopnœa and await the conclusion After two hours of this I usually fell asleep, with the light still on Getting up to turn off the light I found to be fatal—*asthma is twice as bad in the darkness* It is also vital not to cough unless it is absolutely inevitable , one gets into a vicious circle of impotent coughing But what I still don't know is why I ever got the attacks , or, if you like, why I sometimes didn't I never had them at school , at Oxford I rowed boats with the success of the over-compensated I never had them sleeping in the open, even when it rained all night and we didn't have a tent But at some ten different houses in the holidays I had asthma like fun It used to start with prodromal symptoms between tea and supper , your lungs didn't quite expand properly and my mother used to notice my shoulders hunching as the accessory muscles started in, but it wasn't what you'd call dyspnœa The real dyspnœa started about two in the morning and made one feel not only breathless, which was endurable, but remarkably stupid, which wasn't (Our chaplain at Oxford, a confirmed asthmatic, could never remember anything , he once asked a man if it was he or his brother who was killed in the war) And then I discovered the pyscho The first essential was to be busy all day, and leave a few things unfinished Then you would say to yourself, " How very nice to wake up with asthma in the night , then I could write to Auntie Vi " Nowadays I can say something like this, and with justification, every single night (finals on December 8) And asthma ? Never heard of it There is obviously some quite simple, even crude, psycho-analytical explanation, but I wish I knew what it was It works so very much better than ephedrine

* * *

On a cold grey afternoon early in November I had to look for the public lavatories at the end of the street, for the mortuary lay behind them A man on our panel had died without consulting us and the coroner wanted to know why A tall, gaunt policeman half-opened the door for me and I stepped from the cold wind to a colder silence and the glare of electric light Under a stained waterproof sheet I found that which I sought, but I did not know him In the next compartment was the body of a young suicide , the entry wound was just above the right ear and the back of the head was cratered, but the front hair, forehead and face were like some proud Apollo's A fleeting suspicion crossed my mind that those who spurn their living days see immortality The policeman had a bad cold , he told me he had been up for the last two nights, his overtones echoing from the bare walls, and, as he blew his nose, the smell of eucalyptus gaining on that of disinfectant and the fleshy smell of cadaver We grew silent , my thoughts, usually so objective, turned inwards, and I felt as I used when I read the stories of Dostoyevsky Suddenly came the slamming of a car door, the jingle of keys, and the brisk step of the pathologist Here was a man who carried an overpowering atmosphere with him—of the home, the club, and probably the golf and rugger world He chatted as he changed, but the long incision with its single by-pass, although it was made with verve, was in silence The costal cartilages cracked almost merrily and except for the staccato verdict the examination proceeded with mute zest It was not till the last brisk stitch was tied in perfect symmetry that I realised what had been running through his mind—" By Jove, if we corner Rommel "

* * *

Barring accidents, one has a reasonable chance that a posting in my particular branch will last for six months, so when within a fortnight of arrival at a hospital unit in an agricultural district I came across a pedigree Large White sow one week off farrowing with her second litter offered for sale at £10 I decided to take a chance on seeing her through at least one reproductive cycle and bought her She was cheap because very little meal is available to farmers for pig-keeping, and *there is is sold at a price* which in relation to the c price of fat pigs leaves very little in it Now the pi not owe its well-established position in agricu systems all over the world to its capacity to consume convert rapidly into meat large quantities of slop meal , that is the dependant position into which it w forced by our decadent prewar agriculture , it served an elaborate catalyst to the food-conversion industry and some even thought they saw the day coming when laboratory controlled tissue cultures would altoget displace the pig Pigs qualified in the dawn of agri culture for the position they hold because of thei fecundity and also for their capacity to survive lean times and yet be ready to turn the days of plenty to good account Thus, a sow is mated when one year old and thereafter rears two litters of 8 pigs a year (that is taking the average for the country , my sow has reared 12 fine pigs), and her useful life is 3 *to* 4 years However, it was only after a holiday in Jugoslavia 5 years ago that I fully realised the valuable part pigs can play in serious farming

The land I'm thinking of was farmed by peasants, their houses and buildings grouped together in a village which was surrounded by wide unfenced tracts of arable land divided into separately cultivated small holdings *Wheat and barley were the principal crops, but each* farmer kept up to half a dozen pigs housed at nights in his homestead and grazing collectively by day under the care of a communal swineherd It was January then and the first falls of snow had come but still the pigs continued as they had been doing since the harvest in late July picking their living off the stubbles It was an entertainment to watch the herd *returning about* teatime down the village street, each group breaking off and trotting up to its own yard for the evening swill, banging and squealing impatiently if the owner had carelessly left his yard gate shut This is no isolated local phenomenon—herds of swine were a feature of the Bible countryside and no-one supposes that swineherds were a product of the imagination of *our classical* authors For the fact is that there is no way of harvesting grain, not even the latest combine threshers, that can prevent a spillage of less than 5%, and with ordinary methods and the average harvest weather in this country the loss is commonly two or three times that To leave so much on the ground is only possible in an age of reckless plenty , enormous numbers of *poultry could recover* some of it but it is impossible to maintain them for the rest of the year , and so unless it is to be wasted the pig must pick it up, grow large and healthy and prepare himself for the finishing stages of fattening in a stye Of the pig's frugality also the forests of Jugoslavia afforded an illustration, for in them lived the wild boar, the most prized game of *my host* It was not very *much smaller* than the domestic pig, yet without any artificial feeding, or, I was told, ever raiding the corn fields it maintained itself in excellent condition I still recall with relish the joints of fat wild boar which had been pickled and then stewed in red wine

My sow farrowed, as most do, without obstetrical aid *and proved a good grazer* and a splendid milker, but there was little meal and that of poor quality to supplement the grass and at first she lost flesh , however, from the time the first stubble was cleared neither she nor her litter have ever looked back *At first* it was, " Ah, Sir, tha'll need to be giving her plenty o' good middlings or she'll never do all they young pigs " But later it became, " Well ! I never did see a better reared litter , no, nor neither a cheaper 'un She b'aint *had* no more than half a bag o' corn not all along " So now I'm building a stye where the sow can go with a run over 3 acres of woodland, *and I'm* expecting her to complete the second part of the Jugoslav picture When the stubbles are quite cleared the litter will have to go as store pigs to be fattened by a swill feeder I'll warrant they'll be good doers They have played a *real* part in agricultural economy and their example, Mr Hudson, should be widely followed throughout the country

* * *

One of many things I look forward to at the end of the war is a sharp decline in enthusiasm for first-aid How many courses of lectures on this controversial subject I shall have delivered by that time I *shudder* to think. Meanwhile the correction of examination papers occasionally affords a gleam of humour. Here, for instance, is Mr Fibula on the treatment of epileptic fits "To prevent the tongue getting bitten place a receptacle in the mouth" Now listen to old Auntie Sternum on the treatment of a burst varicose vein "Place the patient in a laying position " (she keeps poultry, of course) Mr Clavicle has a complicated mind "The blood in a varicose vein," he assures us "moves in both directions", very confusing of it Miss Ulna may fairly be described as a pessimist "An epileptic fit which may occur in youth and continue into old age" is her opening gambit, no relief, you see Mr Femur, on the other hand, believes in the abstract Lay patient down away from all things '—but he unfortunately omits to state how this is to be done The idiotic question on the functions of the liver produced some gallant efforts Thus according to Miss Pelvis, the liver is an involuntary muscle and the Scapula sisters, collusive as ever, gave us the following gem "The liver is a small organ situated just below the stomach opposite to the spleen its function is to distribute the food juices and retain the bile"—a sort of food office, as you might say

* * *

Much as I enjoy reading your peripatetic correspondents, some comment is called for when they show a complete ignorance of the recent literature Your correspondent who wrote on the subject of Little Men may only have been a student—but he should surely have heard of Rosenschmalz's now classic monograph (*Homunculus und der homunculose Unterblutschenhauptwissenschaft* Zurich 1936) The date itself is enough to discount any claim to priority on the part of the American he mentions In the second edition moreover, is mentioned the important work of A K Routh my beloved teacher who first realised the dependence of the homunculi on drugs, without which the pathology of Addison's anæmia is incomprehensible Routh showed that the marrow homunculi ("Little Men" is surely rather a crude term ?) are compelled to eat the nuclei extruded from normoblasts and that in the absence of the dulling effects of Castle's hæmatinic principle (the "sauce of blood-formation ') they are unable to bring themselves to do any such thing, with the natural result of the familiar blood-picture Later I myself put in my tiny oar (unpublished) and have been able to show that the effect of the sulphonamides is to inebriate and later over-inebriate the *Bluthomunculosen* into gnawing first pathogenic bacteria and then polymorphs Again, surely Rosenschmalz and his school have put urinary homuncular psychopathology beyond all question and the excusable error of Rosenschmalz himself in believing in his enthusiasm that he saw a homunculus peering through the opposite end of a cystoscope should not be allowed to obscure his real contribution the discovery that hæmaturia is due to the homunculi playing pooh-sticks with red blood-cells down the gently trickling waters of the tubules I could extend this discussion still farther did I not know how severe are the calls on your space—but perhaps your correspondent ought to look things up for himself ?

* * *

I was talking round the fire the other day and telling the medical staff how I had just made a post-mortem examination of a man with complete transposition of all his viscera, and what an odd sensation it was opening a heart perfect in every respect but built the wrong way round The drawling voice of the hospital wag, deeply ensconced in an armchair, chimed in with "Did you by any chance ascertain whether his blood-sugar was lævulose ?"

* * *

A book that has altered my line of thought for a time at any rate is *Design and Purpose* by Professor Wood Jones This energic concentration masquerading as molecules, corpuscle cities, liver and kidney states imperial brain, this professor of anatomy one of the brightest of a species uneasily dominant for a speck of time (whatever that is !) on a sun's castaway a third-class sun a cooling castaway—this man has dared to peer beyond the scope of groping human sight, vastly above, vastly below, and on the horizontal plane has cast historic eyes a few light-seconds back, has gathered in these messengers of his and believes he reads design And then like some far traveller, home returned with Doric paints he tries to show again these scenes to Doric minds, tongue-bound by man-made sounds, to paint the pattern and unfold design But I have a sneaking suspicion that the word "purpose" may be a misconception of struggling humanity and is part of the design

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M P

The more encouraging prospect opened up by the Allied attack on North Africa, this turning of the flank of the Axis armies in Europe, has had a stimulating effect on Parliament There is likely to be more criticism, and not less, and the lively debate on equal pay for war injuries of men and women foreshadows other debates in the future Mrs Tate moved and Dr Summerskill seconded the amendment on which the vote took place and both speeches were good, but that of Mrs Tate outstanding in its clear and simple appeal for justice and in its direct and vigorous argument The amendment was opposed by the Government, but they could only muster 229 against it, and despite the Government's attitude 95 members—the largest number since the Government was formed—voted against them and for the amendment

Reference was made during this debate to a demonstration of the use of artificial limbs, which was attended by a much larger body of MPs than is often seen in the House itself Mr R L Kelham chief limb surgeon of the Ministry of Pensions, presided over the demonstration Mr Ernest Bevin was in the chair, and the Minister of Pensions at the end of the proceedings moved a vote of thanks to those who had shown how excellent their limbs were and said. "Money is not enough" It is not yet known however whether this sentiment is to be regarded as a statement of Government policy Mr Kelham told us that there were 45 000 cases at Roehampton and sixteen subsidiary centres A schoolgirl of twelve with a below-knee amputation skipped down the room, and Captain Maxwell of the MOP staff dazzled us all by the uncanny dexterity with which he used a multiplicity of separate gadgets fixed to his artificial left arm—to plane hammer screw, chip metal and perform many other skilled operations. An RAF man with an above-knee right and below-knee left amputation was serving as a fighter-pilot—Flying-Officer Bader was his inspiration A many-fingered claw which could be used by a handless pilot to control a plane gave a Wellsian touch to the scene, for it might have been the end of the tentacle of one of the Martians

Service pay and allowances have come up again, the Government announcing some increases which do not, however meet the demand recently put forward by a deputation of members to the Minister of Pensions One of the anomalies of the position of the wife and children of serving personnel enlisted during this war is the provision of medical attendance Doctors' bills up to a small amount may be met by the Ministry but apart from that, and in the absence of money to pay a Serviceman s wife or child is referred to the poor-law authority for treatment In view of the existence of the elaborate EMS hospital organisation this seems both cumbrous and ineffective

The announcement by the Minister of Health of the setting up of a medical committee to advise him on "medical aspects of problems relating to the health of the people" is an important step The list of members is a good one, broadly representative of the medical profession but it omits any special representation of the fighting Services, and it would be improved by securing such representation on its civilian as well as its Service side. Many of the medical problems of the immediate post-war period will be world-wide problems in which Service experience will be of the greatest value

Child Adoption

Mr G Mander asked the Home Secretary whether he was now able to state his decision with reference to bringing into operation the Adoption of Children Act, 1939 —Mr H Morrison replied The Parliamentary Under Secretary of State has received this week deputations on this matter from the principal child-welfare organisations and also from the Woman power Committee I propose to consider their representations before arriving at a decision

In England Now

A Running Commentary by Peripatetic Correspondents

PSYCHOGENIC asthma is a very odd thing. I know mine was psychogenic because I could always beat it by a crude bit of psycho applied before the attack. During the attack the only thing to do was to read a book in a position of orthopnoea and await the conclusion. After two hours of this I usually fell asleep, with the light still on. Getting up to turn off the light I found to be fatal—asthma is twice as bad in the darkness. It is also vital not to cough unless it is absolutely inevitable; one gets into a vicious circle of impotent coughing. But what I still don't know is why I ever got the attacks; or, if you like, why I sometimes didn't. I never had them at school; at Oxford I rowed boats with the success of the over-compensated. I never had them sleeping in the open, even when it rained all night and we didn't have a tent. But at some ten different houses in the holidays I had asthma like fun. It used to start with prodromal symptoms between tea and supper; your lungs didn't quite expand properly and my mother used to notice my shoulders hunching as the accessory muscles started in, but it wasn't what you'd call dyspnoea. The real dyspnoea started about two in the morning and made one feel not only breathless, which was endurable, but remarkably stupid, which wasn't. (Our chaplain at Oxford, a confirmed asthmatic, could never remember anything; he once asked a man if it was he or his brother who was killed in the war.) And then I discovered the pyscho. The first essential was to be busy all day, and leave a few things unfinished. Then you would say to yourself, "How very nice to wake up with asthma in the night; then I could write to Auntie Vi." Nowadays I can say something like this, and with justification, every single night (finals on December 8). And asthma? Never heard of it. There is obviously some quite simple even crude, psycho-analytical explanation, but I wish I knew what it was. It works so very much better than ephedrine.

* * *

On a cold grey afternoon early in November I had to look for the public lavatories at the end of the street, for the mortuary lay behind them. A man on our panel had died without consulting us and the coroner wanted to know why. A tall, gaunt policeman half-opened the door for me and I stepped from the cold wind to a colder silence and the glare of electric light. Under a stained waterproof sheet I found that which I sought, but I did not know him. In the next compartment was the body of a young suicide; the entry wound was just above the right ear and the back of the head was cratered, but the front hair, forehead and face were like some proud Apollo's. A fleeting suspicion crossed my mind that those who spurn their living days see immortality. The policeman had a bad cold; he told me he had been up for the last two nights, his overtones echoing from the bare walls, and, as he blew his nose, the smell of eucalyptus gaining on that of disinfectant and the fleshy smell of cadaver. We grew silent; my thoughts, usually so objective, turned inwards, and I felt as I used when I read the stories of Dostoyevsky. Suddenly came the slamming of a car door, the jingle of keys, and the brisk step of the pathologist. Here was a man who carried an overpowering atmosphere with him—of the home, the club, and probably the golf and rugger world. He chatted as he changed, but the long incision with its single by-pass, although it was made with verve, was in silence. The costal cartilages cracked almost merrily and except for the *staccato* verdict the examination proceeded with mute zest. It was not till the last brisk stitch was tied in perfect symmetry that I realised what had been running through his mind—"By Jove, if we corner Rommel"

* * *

Barring accidents, one has a reasonable chance that a posting in my particular branch will last for six months, so when within a fortnight of arrival at a hospital unit in an agricultural district I came across a pedigree Large White sow one week off farrowing with her second litter offered for sale at £10 I decided to take a chance on seeing her through at least one reproductive cycle and bought her. She was cheap because very little meal is available to farmers for pig-keeping, and there is is sold at a price which in relation to the price of fat pigs leaves very little in it. Now the pig not owe its well-established position in systems all over the world to its capacity to consu convert rapidly into meat large quantities of meal; that is the dependant position into which it forced by our decadent prewar agriculture; it served an elaborate catalyst to the food-conversion in and some even thought they saw the day coming laboratory controlled tissue cultures would alt displace the pig. Pigs qualified in the dawn of culture for the position they hold because of fecundity and also for their capacity to survive times and yet be ready to turn the days of plenty to account. Thus, a sow is mated when one year old thereafter rears two litters of 8 pigs a year (that is t the average for the country; my sow has reared 12 pigs), and her useful life is 3 to 4 years. However, it only after a holiday in Jugoslavia 5 years ago that I realised the valuable part pigs can play in serious farming.

The land I'm thinking of was farmed by peasant their houses and buildings grouped together in a villag which was surrounded by wide unfenced tracts of arabl land divided into separately cultivated small holdings Wheat and barley were the principal crops, but eac farmer kept up to half a dozen pigs housed at nights i his homestead and grazing collectively by day under th care of a communal swineherd. It was January then and the first falls of snow had come but still the pig continued as they had been doing since the harvest i late July picking their living off the stubbles. It was a entertainment to watch the herd returning about teatim down the village street, each group breaking off an trotting up to its own yard for the evening swill, bangin and squealing impatiently if the owner had carelessly left his yard gate shut. This is no isolated local pheno menon—herds of swine were a feature of the Bible coun tryside and no-one supposes that swineherds were a product of the imagination of our classical authors. Fo the fact is that there is no way of harvesting grain, no even the latest combine threshers, that can prevent a spillage of less than 5%, and with ordinary methods and the average harvest weather in this country the loss i commonly two or three times that. To leave so muc on the ground is only possible in an age of reckless plenty enormous numbers of poultry could recover some of i but it is impossible to maintain them for the rest of the year, and so unless it is to be wasted the pig must pick it up, grow large and healthy and prepare himself for the finishing stages of fattening in a stye. Of the pig's fru gality also the forests of Jugoslavia afforded an illustration for in them lived the wild boar, the most prized game o my host. It was not very much smaller than the domes tic pig, yet without any artificial feeding, or, I was told, ever raiding the corn fields it maintained itself in excellent condition. I still recall with relish the joints of fat wild boar which had been pickled and then stewed in red wine.

My sow farrowed, as most do, without obstetrical aid and proved a good grazer and a splendid milker, but there was little meal and that of poor quality to supplement the grass and at first she lost flesh; however, from the time the first stubble was cleared neither she nor her litter have ever looked back. At first it was, "Ah, Sir, tha'll need to be giving her plenty o' good middlings or she'll never do all they young pigs." But later it became, "Well! I never did see a better reared litter; no, nor neither a cheaper 'un. She b'aint had no more than half a bag o' corn not all along." So now I'm building a stye where the sow can go with a run over 3 acres of woodland, and I'm expecting her to complete the second part of the Jugoslav picture. When the stubbles are quite cleared the litter will have to go a store pigs to be fattened by a swill feeder. I'll warrant they'll be good doers. They have played a real part in agricultural economy and their example, Mr Hudson, should be widely followed throughout the country.

* * *

One of many things I look forward to at the end of the war is a sharp decline in enthusiasm for first-aid. How many courses of lectures on this controversial subject I shall have delivered by that time I shudder to think. Meanwhile the correction of examination papers occa

Vaccine Lymph

Mr S P Viant asked the Minister what alterations had been made in the regulations governing the production of calf lymph, and whether more living bacteria were allowed in the lymph than formerly —Mr E Brown replied I have recently made an order modifying the tests for the purity of vaccine lymph. The new order allows an increase in the total number of living bacteria and other visible micro organisms, but it provides safeguards against harmful micro-organisms which are at least equal to those previously prescribed

Miners Medical Service

Mr W Gallacher asked the Minister of Fuel and Power when the scheme for a miners' medical service was to be published and how long it would be before the scheme was put into operation.—Major Lloyd George replied The scheme has already been described in broad outline by the Joint Parliamentary Secretary in the coal debate of Oct 1 (*Lancet*, Oct 10, p 437) I cannot give a precise date on which the scheme will be put into operation, as its introduction must be gradual I am however hoping to be able to fill a number of the necessary medical posts in the near future

Scheduled Diseases in S Wales Coalfield

Major Lloyd George, Minister of Fuel and Power, informed Mr J Griffiths that the number of persons in the South Wales coalmines certified by examining surgeons in respect of scheduled industrial diseases in the year 1938 was 1827

Supply of Technical Books

Mr W A. Colegate asked the President of the Board of Trade whether he was aware of the unsatisfactory position of the supply of technical books, and whether he was prepared to arrange the supply of paper to publishers in such a way that all standard technical books might be available in sufficient quantities for students at technical schools and colleges —Mr E. H. Dalton replied There has necessarily been some reduction in the publication of technical books, but there appears at present to be no serious shortage of such books Special arrangements have already been made to assist the publication of books of particular importance to the war effort, including technical books, and I am considering further measures for increasing the supply of these books

Utility Toothbrush

Dr H B Morgan asked the President whether he would consider, in view of the influence of war conditions on the nation's teeth, the advisability of marketing a utility tooth brush of good quality and durability for public purchase and use, especially having regard to the poor specimens now available in the market —Mr Dalton replied I am already giving consideration to this matter

Medical Exemptions from Fire-watching

Sir Adam Maitland asked the Home Secretary how many men and women had claimed exemption from fire-watching on medical grounds, and what steps were being taken to have their claims examined. Mr H. Morrison replied About a quarter of a million applications had been dealt with by the tribunals up to February last when the Ministry of Health made available the services of their regional medical officers A large part of the outstanding cases have been disposed of under these arrangements In order to relieve the tribunals, I propose shortly to amend the orders to provide that such applications shall be settled by the regional commissioner on the advice of a medical referee appointed by the Ministry of Labour and National Service

Medical Practices

Sir Ernest Graham-Little asked the Minister under what powers officials of his department were empowered to dictate to patients as to what doctors they were allowed to consult, or to doctors as to what patients they were allowed to treat; and as instances of this of which he had been informed had occurred, would he take steps to prevent their repetition.—Mr E. Brown replied Officials of my department are not empowered to dictate either to patients or to doctors in the manner suggested. I understand that the question refers to an incident which was mentioned in recent correspondence in the press and is connected with arrangements which have in many areas been made by insurance practitioners for the purpose of protecting the practices of doctors who are on service

SCOTLAND

NORMAN WALKER

Here in Edinburgh we understand the loss sustained to dermatology through the passing of Sir Norman Walker As a teacher he was pre-eminent His clinical lectures were practical and always interesting He taught dermatology as a part of general medicine, and although practising as a specialist he never lost sight of the fact that the student was being educated as a general practitioner He was more interested in the common skin diseases than in the dermatological rarities He did a great deal of pioneer work in the early days of X rays He was the first to treat ringworm of the scalp with X rays, but as he did not give doses sufficient to bring out the hair, no benefit resulted Some years later when Sabouraud published his method of treatment by X-ray epilation, Walker at once started to use it systematically, so that the first steps were then taken which gradually reduced cases of scalp ringworm in Edinburgh to an insignificant number He was also particularly interested in lupus vulgaris, and by the use of tuberculin both locally and generally, by X rays and Finsen light and latterly by general ultraviolet ray therapy, he obtained excellent results in a disease the cure of which had been looked upon as practically hopeless He started a special clinic where these patients attended regularly for treatment Many cases had lasted for years and lost all hope of cure Owing to their facial disfigurement they were often social outcasts, and when they found someone who took an interest in them they came for treatment from all over Scotland Even when he retired after fourteen years as assistant physician under the late Dr Allan Jamieson and eighteen years in charge of the skin wards of the Royal Infirmary, Edinburgh Walker continued to take a special interest in these cases and acted as extra-physician for the treatment of lupus by ray therapy Walker's contributions to medical literature were many and varied He translated from the German Hansen and Looft's book on *Leprosy* and Unna's huge volume on the *Histopathology of the Skin* Both these undertakings especially the latter, entailed a tremendous amount of hard work In 1899 he first published his own *Introduction to Dermatology*, now in its tenth edition, written in the same interesting manner in which he lectured and full of useful, practical instruction

Sir Norman had a logical judicial type of mind and was a clear thinker who could express himself clearly He had a high sense of public duty, as was shown by his many-sided activities outside his practice No-one was better able to give sound advice to those in difficulties with medical ethics, and in trouble one could always count on his sympathetic interest Soon after the end of the last war he was found to be suffering from diabetes In spite of treatment he slowly became worse, till it looked as if his days were numbered Though very ill he continued to carry on all his duties and refused to give in Then, thanks to the newly discovered insulin his life was saved, and although he was never again capable of physical exertion his mental powers remained as alert as ever. He possessed, what is not common among medical men a combination of medical acumen and skill with organising and business ability In whatever sphere of life he had been placed he would have made his mark. As it is, medicine in Britain and in Edinburgh in particular, is the poorer by his passing

R C L

MINOR VACCINATION DIFFICULTIES

Stirlingshire practitioners do not like their county council charging them for the calf lymph they used in the recent vaccination campaign, and at Falkirk any plan of mass vaccination is in abeyance until the town council has further considered the MOH's plan of campaign to meet an emergency if it should arise Such difficulties need prompt adjustment to avoid holding up a measure of national importance Doctors vaccinate their panel patients free of charge with lymph supplied by the insurance committee or in an epidemic, by the Government through the local authorities When a MOH orders free vaccination in his area he opens clinics where the work is done by members of his own staff often with the help of local practitioners paid on a sessional basis At their own surgeries practitioners continue to vaccinate their panel patients free of charge while charging private

QUESTION TIME

Medical Advisory Committee to Minister of Health

Sir Francis Fremantle asked the Minister of Health what steps he was taking to keep in touch with representative medical opinion in regard to the planning of the future of health services —Miss F Horsbrugh replied The Minister has for some time felt the need for associating with the work of the Ministry a representative body of medical men and women engaged mainly in the clinical practice of their profession He has therefore set up a medical advisory committee whose terms of reference are to advise him on the medical aspects of problems relating to the health of the people

The following is the list of members

President of the Royal College of Physicians of London
President of the Royal College of Surgeons of England
President of the Royal College of Obstetricians and Gynæcologists
Chairman of Council of the British Medical Association
Dr G C Anderson
Dr J C Arthur
Miss Alice Bloomfield
Dr J A Brown
Mr E Rock Carling
Dr J A Charles
Prof Henry Cohen
Dr W Allen Daley
Lord Dawson of Penn
Dr E A Gregg
Lord Horder
Sir Wilson Jameson
Dr W S Macdonald
Dr Alan Moncrieff
Prof R M F Picken
Prof Harry Platt
Dr A T Rogers
Dr, Daniel Twining
Dr Oscar Williams
Dr Albertine Winner (lieut colonel)

Industrial Health Research Board

Mr M P Price asked the Lord President of the Council what progress had now been made in the work of the Industrial Health Research Board since its reorganisation and expansion , whether fresh problems were being tackled and adequate personnel made available for the purpose , whether there was satisfactory cooperation with other Government departments , and whether steps were now being taken to carry knowledge of the board's work in simple terms to both employers and employees —Sir J Anderson replied The board, since its recent reorganisation by the Medical Research Council, has initiated investigations into a number of new problems, in addition to continuing work on earlier lines Work on further subjects is being planned Additions to the investigating staff are being made as required, although there are naturally difficulties in the way of securing suitable personnel under present conditions The work of the board is conducted in close touch with the Factory Department of the Ministry of Labour and National Service, and facilities for investigation have been given in establishments under the control of the Ministry of Supply The policy of the council is to publish the results of research work, both old and new, in brief emergency reports written in simple terms

Medical Schools and Women Students

Mr G Mander asked the Minister of Health the position with regard to the committee on medical schools which was considering the desirability of increasing the facilities for women to study in medical schools in London , and when a report was expected —Miss F Horsbrugh replied The committee was appointed by the Secretary of State for Scotland and the Minister of Health to inquire into the organisation of medical schools I cannot give a date for the report , the issues involved are of first rate importance and will demand some time for examination The particular question mentioned is of course one only of the very large number of questions that will be considered by the committee

Control of Malaria and Yellow Fever in West Africa

Dr Morgan asked the Under Secretary of State for the Colonies whether any statistics were available of the incidence of malaria in Sierra Leone and other parts of West Africa during the last three years , and whether there was any coordination of malaria control as an item of war strategy in West Africa or whether the different services were left in control in their several spheres and special areas —Mr Harold Macmillan replied Complete statistics for malaria generally in Sierra Leone and elsewhere in West Africa for the last three years are not available, but special attention has been given to the question since the outbreak of war, and a mission was sent out to investigate and advise on the measures to be taken against the incidence of malaria in Freetown The measures recommended are being implemented as far as possible with funds provided under the Colonial Development and Welfare Act, and including permanent measures of control Similar attention has been given to the problem in other West African Dependencies There is the closest coordination between the civil administration and the Services, including the USA authorities, in dealing with this problem, and in addition officer of the Colonial Medical Service visits all seaports British West Africa to advise on the coördination of measures which are being taken

Dr Morgan Are swamps in the vicinity of chosen drome sites in West Africa being effectively drained or o as part of an effective malaria control direction , and is officer of the Royal Air Force, a civilian malariologist or officer of the Royal Army Medical Corps responsible f preventive health action at or in the vicinity of these sites — Mr Macmillan replied Very active control measures a malaria and yellow fever are being taken at all airfield sites in British West Africa The executive authority for preventive health action is usually an officer of the RAF, who in general control airfield sites in British West Africa The RAF have their own specialist officer to deal with the problem and an experienced entomologist seconded from the Colonial Medical Service has recently been visiting all airfields in British Africa.

Dr Morgan Have any reports been received from the Resident Minister of State on malaria , has the advantage of screening as an effective safeguard been considered and to what extent has it been adopted , and has consideration been given to the desirability of appointing one experienced malariologist in effective control and directly responsible to the Resident Minister for a concerted plan to safeguard the health of all troops as well as civilians in this area —Mr Macmillan replied Every aspect of this important problem is receiving the most careful consideration by the civil and Service authorities concerned in conjunction with the United States military authorities in West Africa Lord Swinton considers that satisfactory machinery has been devised for coordinating measures to deal with this problem

Compensation for Industrial Disease in Nigeria

Dr Morgan asked Mr Macmillan whether, in the workmen's compensation legislation in the Colony and Protectorate of Nigeria, any provision was made for compensation for industrial diseases on the lines of the statutes and regulations in Great Britain —Mr Macmillan replied Such provision was not made in the Colonial Office model ordinance upon which the Nigeria Workmen's Compensation Ordinance, 1941, was based The reasons for this were the considerable difficulties which were likely to be experienced in many Colonial territories in diagnosing such diseases and the even greater difficulties in determining whether, in any particular case, the disease was in fact directly and specifically attributable to the workman's employment An additional complication arises from the unfortunate prevalence of diseases such as malaria and hookworm, which lower the resistance of the worker to other diseases It has been found by experience in this country that even when a case has been dealt with by a medical practitioner familiar with the particular employment and practising in a district where the particular occupational disease is most usually found, it is frequently necessary for it to be referred to a specially qualified medical referee appointed to deal with such cases As there were likely to be very few medical practitioners in the Colonial Dependencies with the necessary specialised knowledge and experience, it was felt that there might be a considerable risk of inequitable awards being made if provision for compensation for occupational diseases were included in the model ordinance and adopted by the African governments for whose assistance the model had been prepared

Sewage Disposal at Sierra Leone

Dr Morgan asked the Secretary of State for the Colonies what is the present method of sewage disposal in Sierra Leone and especially Freetown , whether the sewage canals in the town are still open, and the nightly emptying of buckets therein still obtains , whether the sewage disposal in troop areas as contrasted with civilian regions has been improved by the building of an Otway pit , and whether such methods are being more extensively used in West Africa ?—Colonel O Stanley The existing methods of sewage disposal in Sierra Leone are by bucket in urban areas and by pit latrines in rural districts There are a few septic tank latrines in urban areas, but these are exceptional The method of disposal of sewage from the buckets is by emptying into the sea or into covered earth pits It is understood that the Otway pits installed by the military authorities have proved satisfactory Improved and more modern methods of sewage disposal are being considered in the British West African territories the oligarchy of the many " when he meant " the tyranny of the crowd " and this unfortunate expression was punctually and pleasantly pilloried in *Punch* A good deal might be said in extenuation of this mistake made by a man whose formal education stopped probably at ten or eleven There is no point in borrowing " calligraphy " from the Greek meaning good or beautiful writing if we use it merely as a synonym for handwriting and then qualify it with illegible Such a slipshod expression blurs the fine distinctions of which our language is capable

Wakefield REGINALD LAWRENCE

*** The use of the word calligraphy for penmanship generally is not so modern as all that The OED gives the date 1645 —ED L

Obituary

DONALD STEWART MIDDLETON

M B EDIN F R C S E , BRIGADIER A M S

Brigadier D S Middleton who has died while on active service in England left his work as assistant surgeon to the Edinburgh Royal Infirmary at the outbreak of the war for the post of ADMS Anti-Aircraft Defences of Scotland Middleton was born in South Africa in 1899 and educated at Edinburgh Academy and University He qualified in 1921 became a fellow of the Royal College of Surgeons of Edinburgh in 1925 and of the Royal College of Surgeons of England a year later After various house-appointments, including one at the Paddington Green Children's Hospital, he became clinical tutor at the Edinburgh Royal Infirmary and assistant surgeon to the Royal Hospital for Sick Children Appointments as assistant surgeon to the Infirmary, surgeon to the Deaconess Hospital and lecturer in surgery in the School of Medicine of the Royal Colleges followed He was the author of sections in Miles and Wilkie's *Manual of Surgery* and in their *Operative Surgery*, and he also published articles dealing with congenital abnormalities

Lafayette

One of his friends writes I never knew why Donald Stewart Middleton was always called Sam through the length and breadth of Scotland I never asked why One just took it for granted that it was a term of endearment I knew him for many years before the war, as surgeon, consultant and friend, and saw a lot of him at the meetings of surgical, medical or medico-political societies and clubs, for his tastes were catholic and anything but circumscribed Watching him measuring his strength against skilful antagonists listening to him asking awkward questions with that unerring judgment which led him to grasp the essential core of the matter, hearing him summing up the result of a debate, I thought that here was no ordinary surgeon and here was no ordinary man For some time Middleton's keen diagnostic sense had made him war-conscious He joined the Territorial Army and rose rapidly, so that the outbreak of war found him in the rank of full colonel as ADMS Anti-Aircraft Defences of Scotland It was a new branch of the medical services and guided by Brigadier (now Major-General) P H Mitchiner, he threw himself wholeheartedly into the task of building it up and organising it surely and steadily for the wrath to come And so it was that in September, 1939, I met a changed Sam He was no longer just a great surgeon in the making, he was forthwith a great man and an inspired and inspiring leader of men He always had had a magnificent physique, but in uniform he looked even more imposing and radiated confidence and personality

But he never forgot that he was primarily a doctor, and he believed firmly that from the ruin and ashes of war there would emerge phœnix-like, a less selfish self-seeking and more coöperative and integrated medical service The medical profession has lost an honest and single-minded administrator whose wise counsel will be sorely missed when post-war medical problems will require our best

RONALD EDWIN SHAW LEWIS

M C, M B EDIN , CAPTAIN R A M C

Captain R E S Lewis was killed in action in the Middle East during October at the age of 28 He was the son of Dr A J Lewis of Birkdale and was educated at Mill Hill and Edinburgh University where he graduated in 1939 After acting as house-surgeon at the Royal Victoria Hospital, Dover, he declined a resident appointment at the Edinburgh Royal Infirmary and entered the RAMC in February, 1940 In September, 1941, he went to Egypt with a light field ambulance and in July, 1942, became regimental medical officer to the Queen's Bays He was awarded the military cross for gallant service

Finch Clacton

HOWARD ENSOR

C B, C M G, C B E D S O M B DUBL

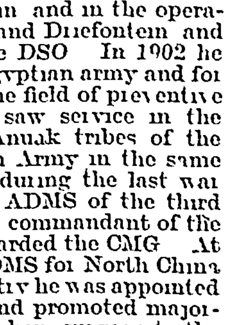
MAJOR-GENERAL, LATE RAMC, RTD

Major-General Ensor, a colonel commandant of the RAMC since 1937, who died on Nov 22 was a courageous officer full of grit and common sense Born at Cheltenham in 1874 he was educated at Trinity College, Dublin where he graduated BA in 1895 and MB two years later Before taking up his commission in the RAMC in 1899 he went as medical officer with the Lapai expedition His service in West Africa was interrupted by the South African war, he was in the advance on Kimberley, including the action at Magersfontein and in the operations at Paardeberg Poplar Grove and Driefontein and for his bravery he was awarded the DSO In 1902 he was seconded for service with the Egyptian army and for the next ten years his work lay in the field of preventive medicine But in 1912 he again saw service in the operations against the Beir and Anuak tribes of the Sudan He returned to the British Army in the same year with the rank of major, and during the last war served in France, for two years as ADMS of the third division In 1918 he was appointed commandant of the RAMC school of instruction, and awarded the CMG At the beginning of 1927 he became DDMS for North China and soon after his return to this country he was appointed DDMS for the Eastern Command and promoted major-general From 1930 to 1933 he was hon surgeon to the King He retired in 1933 and spent some time in Calcutta as superintending surgeon to the British India Steam Packet Company, finally returning to this country to settle at Hawkhurst in Kent General Ensor married in 1912 Miss Gladys Tweedie and they had two sons and one daughter

JOHN RICHARD GLANFIELD HARRIS

M B CAMB, D A

Dr J R G Harris who was killed in August by enemy action while on holiday was a man of many talents with many friends One of them, J D C , who was with Harris at Cambridge and later shared rooms with him in London, recalls his love of music and excellent tenor voice and the zest with which he organised and trained the Christmas troupes at the London Hospital " Harris was keenly interested in games," J D C continues, " and though his physique did not allow him to excel he was a first-class hockey umpire and a very good rugger referee His ability to see the pros and cons of any problem was exceptional and his judgment sound " Harris qualified in 1935 and graduated the following year After holding various house jobs he was appointed resident anæsthetist at the London and quickly became so absorbed in the subject that he decided to specialise in this work Eventually he was elected to the staff of the London as honorary anæsthetist, and he was also on the staff of University College Hospital and the Hounslow Hospital



Elliott & Fry

patients an appropriate fee Stirlingshire apparently takes the view that when a fee is charged the lymph should be paid for by the doctor In the Falkirk plan the local doctors were to be asked not only to help at clinics on a sessional basis but also to vaccinate patients at their own surgeries for a flat rate of 2*s* 6*d* a patient Falkirk practitioners would then be taking a bigger part in the vaccination campaign than those in the rest of Stirlingshire Obviously in an emergency the main thing is to get the job done, which means pooling all the available man-power Whether in time of peril from smallpox the price of lymph should be charged to doctors is a moot point, but it should not be beyond official wit to work out an agreement which would allow doctors to vaccinate their private patients with lymph supplied by the local authorities, so long as it was understood that the price of the lymph should be taken into consideration in fixing an appropriate fee for the occasion Falkirk and Stirling can give a useful lead in finding a way out of these minor troubles

VENEREAL DISEASE

Dr Andrew Davidson, chief medical officer to the Department of Health, said recently that there had been an increase in the incidence of venereal disease in Scotland since the outbreak of war The number of newly infected patients attending civilian treatment centres was 6433 in 1939, 6851 in 1940, and 10,179 in 1941 Newly acquired cases of syphilis in Glasgow numbered 390 in 1939, 580 in 1940 and 909 in 1941, and in Edinburgh 199 in 1939, 230 in 1940, and 444 in 1941 Since every patient who had acquired infection did not report at a treatment centre the figures giving the true position were certainly higher Dr Davidson felt there was need of greater control not only for the sake of the general public and the fighting forces but also for the safety of many Allied troops now in the country, some of whom came from countries where greater protection is ensured

Letters to the Editor

INGUINAL HERNIA

SIR,—With the first two paragraphs of Mr Dodd's letter of Nov 7, in which he says that it is unnecessary to fix the neck of the sac to the abdominal wall and that it is necessary to recognise, define and suture transversalis fascia, I am in complete agreement, but I wish he had stopped here (except for the concluding paragraph), and not given his implied approval to the Bassini operation A study of recurrent hernias made possible by the enrolment into the Services of most of the young manhood of Britain has furnished enough evidence to permit of the following dogma

Any interference with the normal musculature of the inguinal canal in the operative repair of indirect inguinal hernia in the young subject increases the risk of recurrence

The treatment of this common deformity has acquired great importance at the present time Operations for hernia on Service cases are being performed in large numbers, and not always by surgeons of wide experience or under ideal conditions for surgery This is no time for "experimental" surgery—for the devising and trying out of new operations The subject is too urgent for that What we must do is to agree on the most reliable operation which is at the same time the simplest and safest I submit that the operation which best satisfies these requirements for indirect inguinal hernia in otherwise healthy service patients is complete excision of the sac and repair of the transversalis fascia at the site of amputation of the sac, without disturbing the cord from its bed

As regards large and long-standing scrotal hernias, direct hernias and recurrent hernias, the position is not so clear cut Correct selection of cases is of the greatest importance, for from the military standpoint it is of little use operating unless there is a reasonable hope that as a result the patient will be able to carry out his military duties more efficiently All will agree that some form of plastic repair is usually necessary, the more debatable point being the medium used for the purpose Fascia probably has most to commend it—either a local flap, or, if the defect be large, fascia from the thigh A considerable experience of the use of floss silk, and observations of the late results in cases operated on by others has led me to conclude that it is not suitable for general t because if sepsis does occur its effects are likely to ca long invalidism

The problem does not end with the operation I necessary to ensure that the patient is returned to unit in the minimum time compatible with maxim fitness To secure this, graduated exercises are inv: able and are an aid to both physical and mental discipl The regime advised is 3 weeks in bed, 3–4 weeks i suitable BRCS auxiliary hospital, and 4 weeks in convalescent depot Graduated exercises are begun bed on the 12th day, and continued throughout recovery period The patient, on the average, retu to duty 12 weeks from the date of operation, and is t fit to withstand the full rigors of Army training

HAROLD EDWARDS

THE AMPUTEE'S POINT OF VIEW

SIR,—LRCP has had bad luck with limb fitt and limbs because he has a stump which nowaday condemned owing to its bad record The through-k amputation was performed in the last war first, in ca of sepsis where the surgeon feared to amputate thro the muscle mass of the thigh for fear of cutting thro infected tissue planes or infecting them, and secon with the idea of providing an end-bearing stump wl was then in vogue Today we recognise that the throu knee and transcondylar amputations gave very p end-results on account of the following factors

Anatomical —The articular cartilage covering the end of femur did not stand up to direct weight-bearing The blo supply to the covering skin is poor, being solely derived f the small superior geniculate anastomosis, so that it could stand up to weight bearing, especially when stretched (the bulbous condyles

Limb —The thigh corset or socket has to have an opening down the front to permit the bulbous end of the stump b passed down Even when this corset is tightly laced it is snugly fitting, so that the end does not bear weight evenly the bulbous condylar stump, and sweating and friction ca skin eczema and ulcers The axis of the artificial l knee joint cannot be placed at the normal level, thus sitting the appearance through the trouser is noticea The lateral stays and the hinges have to be bent round bulbous end of the socket, causing mechanical weakness undue breadth of the artificial joint

The wearing properties and gait of this amputat are thus poor and LRCP would be much better off w an above-knee stump fitted with an up-to-date stur controlled limb He has only to see a below-k amputee fitted with a standard modern limb to appreci that even an experienced limb fitter often has so difficulty in telling which leg has been lost when he s the amputee walk or play games

Harley Street, W 1 G O TIPPETT

DIAGNOSIS AND TREATMENT OF SCIATIC PA

SIR,—Captain Good describes a method of treatm which is in common use If he had been able to foll up his patients I fear he would have been less satisf with his diagnostic skill and the results of his treatme In my hospital work I see a large number of civilian a Service patients who present the clinical picture that depicts For many years I have injected procaine a other solutions into the tender areas that he enumera and in many cases the relief of pain is immediate T is gratifying but in the majority of cases the sympto soon return It is my experience that the injection m be followed by the local application of physical measu such as heat and massage to the muscles that are spasm An attempt must be made to correct the und lying cause, which commonly is poor posture If thi not done, a draught or some seemingly trivial injury v provoke another and usually more severe attack

FRANCIS BACH

London, W 1

CALLIGRAPHY

SIR,—I must enter an immediate protest against t expression "illegible calligraphy" in your issue of N 21 (p 625) It gave me great pain I once picked u book on English written by two teachers at one of o famous high schools for girls and opening it at rand saw a phrase "if the calligraphy is bad" So much f our teachers! A Labour leader once said in a spee to have a world-wide and not a local appeal This should comprise a research institute in association with the first hospital in the country The hospital should be large, with departments embracing all aspects of medicine and should take the place of one or more of the redundant undergraduate teaching hospitals of London It should form the apex of a regionalised postwar hospital scheme for the country, acting particularly as regards London Here it should act as the head hospital in relation to the teaching hospitals as these individually act to their sector hospitals Its scope, however should be not only local, but national, imperial and international It should have the closest association with the other special hospitals so that each branch of medicine becomes coordinated, and its relation to the vast reservoir of LCC patients should be carefully considered It should be staffed primarily by whole-time professors who must have a prestige and pensionable remuneration eminently attractive to the best men and women in medicine, and be elected from the best medical material in the Empire by the universities Both for the staff and for research workers there should be the widest facilities for interchange with medical personnel throughout the British Commonwealth and with all interested foreign countries

* * *

Such a scheme calls for a new building of key importance to the state situated centrally in London, housing these bodies controlling the interests, professional, research and educative, of the profession The various existing bodies (such as the colleges), most of which have to be rehoused in any case, could retain separate premises within this, but at least they would have the physical opportunity of close cooperation in all their activities, the amenities of a certain degree of community life (as the legal profession has), and in combination could put up a brave and unrivalled showing to the world Whether or not the postgraduate school, the research institute and the hospital should be on the same site, thus forming a compact medical city, is a matter for discussion

This scheme admittedly cuts across many long-established interests and will be unrealisable unless whole-hearted effort is made, but by some such plan British medicine can be made a new and living organism of incalculable value to the people and so to the state, while by fostering international relationships and aiding humanity at large it could play no small part in moulding a more rational and stable world society

Appointments

COCKREM, GWENDOLINE E MRCS resident obstetric officer at St James Hospital, Leeds

WILSON, A J MD EDIN FRCPE medical referee for workmen's compensation for the county court districts of Daventry and Rugby

Births, Marriages and Deaths

BIRTHS

ANDERSON —On Nov 24, at Exeter the wife of Surgeon Lieut-Commander E W Anderson, RNVR—a daughter

BILLINGTON —On Nov 5 at Kampala, Uganda the wife of Dr W Roy Billington—a son

JONES —On Nov 26 at Adlington Hall, Cheshire, the wife of Mr A Norman Jones, FRCS—a son

OSWALD —On Nov 21, the wife of Lieut Colonel Neville Oswald, RAMC—a son

PINKERTON —On Nov 24 at Hitchin Herts the wife of Lieutenant G E Pinkerton RAMC—a son

SUTTON —On Nov 3, at Ripley Surrey the wife of Dr Phillip Sutton, PAFVR of Great Yarmouth and Sidcup—a daughter

VIRET —On Nov 27 at Woking, the wife of Surgeon Lieut-Commander W E Viret RN—a son

MARRIAGES

MCARTHUR—STUART —On Nov 26 at Bearsden Andrew McShee McArthur MB major RAMC to Christina Cecilia Marie Nicolson Stuart

SIR,—When mothers of growing girls meet out shopping and discuss where the very best crossword puzzles are to be got, one is sure to overhear it said—"We always go to Mr Peter Quince for ours, you can always rely on his to be quite free from all objectionable advertising matter" Imagine the consternation in these circles, gentler than the ones you frequent, my good Sir, were I to employ my muse in "pushing" Tom and Dick's trusses, Henry's irregularity pills, or even a "Lancet" publication What abnegation of high principles enrooted in my nature How redolent of commerce! How my enemies would have triumphed (!)

Actually Margaret, my muse, was so wroth at the slightest hint that the pair of us might accept the derogation that she walked out on me without as much as "goodbye," but muttering (as she always does when distrait), "Oh, don't deceive yourself!" She was a good tough muse—she came from the museum at TCD—although "suffering much from spleen and vapours" and other similar ills Unfortunately I had had to Basingstoke her rather cruelly that very morning because she would ogle a lot of rude ABs who shouted crude remarks on the disparity in our ages So now, thanks to you, Sir, I am in the unenviable position of having no muse It irks me not a little, to employ a litotes

As you yourself lent a deft hand in editing this book, you cannot very well review it in your columns A pity, I should have quite enjoyed writing a page or so of highly delectable prose (and incidentally enriching the tone of your publication) instead of all this nonsense where I have with considerable ingenuity to insert awkward words, videlicet "videlicet," and quotations—e g, "This other Eden, demi-Paradise"—without distorting the theme too much but with enough double-crossing traps to snare and delude the poor boobs who fall for that sort of thing

You bade me devise a crossword about "Control of the Common Fevers" Well, you are not getting one from me My objections to doing it are insuperable The book and its twenty-one authors are too good to be taken in vain and the public will be a mutt if it doesn't snap up the entire edition anyhow

Adieu and likewise addio,

PETER QUINCE

ON THE TABLE

THE Cambridge branch of Children's Nutrition Council has published a penny leaflet showing how to plan a war-time diet. It is a table of food values the foods being classed as energy foods, body-building foods those that give calcium, those that give iron, and those that contain vitamin A, the vitamin-B group vitamin C and vitamin D The lists of foods are not hampered by figures but arranged so that the most valuable foods in each class head the list On the back page are a few useful notes which will help in planning the family diet some reasons why national wheatmeal is better than white bread, and ten lines of advice on cooking so as not to lose vitamin C The leaflet is a bargain at a penny and can be had from the branch secretary, c/o Department of Zoology, Cambridge

A BRITISH ACADEMY OF MEDICINE

SIR STEWART DUKE-ELDER, M D ST AND, F R C S
OPHTHALMOLOGICAL SURGEON TO ST GEORGE'S HOSPITAL

THE purpose of these proposals is to suggest a mechanism whereby medicine in this country might play a worthy part in influencing the social changes which are now upon us and are undoubtedly to grow in momentum in the near future More than one body has formulated plans for the state-aided treatment of the sick, and one ministry has recently felt the need for professional guidance but medicine, interpreted in its widest sense as social biology, should have a wider and higher mission—the creation of an environment wherein the fullest attainment of the health, happiness and efficiency of the people is possible British medicine in its present incoordinated state lacking central stimulation guided by unrelated and often competing professional bodies and administered by a dozen ministries, is in no position to assert itself in an integrated manner to confer the benefits it might upon the population or to implement the opportunities of the immediate future in reconstruction research and international influence After the war the state must play a much larger part in administering medicine than hitherto, and if a living science is not to be deadened by bureaucracy medicine must be able to advise the state with a single authoritative voice, and the state should have a single representative body to which to appeal for guidance and support In the second place, in the international sphere at the end of the war the Anglo-Saxon community will be immensely important in the cultural affairs of the world, and if London is to profit by its unique opportunities, and become a world centre of progress and research, British medicine must bestir itself to take a lead rapidly and effectively before the initiative falls into other hands Finally, it is urgent to formulate integrated plans now to foster the national effort which will not cease with the cessation of hostilities, to minimise the social ills which normally accompany and follow wars, and to guide society in the difficult times ahead

For these reasons it is of primary importance that some professional body of recognised authority and influence should be created, not displacing or destroying, but coordinating and augmenting the influence of the present unrelated and relatively impotent bodies, this body would receive the unquestioned confidence of the Government, the people and the profession, and could stimulate a revival of medical progress and research in this country displacing the Continental centres and attracting students and research workers from all over the world Such a body might be called the British Academy of Medicine It should be a corporation with a statutory basis, of compact size, authoritatively selected and wholly divorced from politics It should be supported by and work intimately with the state, be affiliated to the Privy Council and thus responsible through a minister to Parliament

* * *

To perform its functions the academy might have under it the following councils —

1 *A Council of Civil and Social Medicine*, advising on the practice of all civil medicine in this country Its activities might be divided among three committees

(a) *Social medicine* —This committee would advise the Government on questions of social medicine in the widest sense This conception embraces not only such general questions as public health, nutrition, immunisation, reconstruction, town planning and housing, but should also include the organisation and conduct of a national service of preventive medicine for the individual It should start in the antenatal clinic, continue in close conjunction with a revised educational system, and extend—at the least—to the termination of military or other social service It should include physical training, recreational and holiday organisation, and wise and restrained psychological guidance

(b) *Industrial medicine* —To advise industry both *in this* country and overseas from the biological aspect as to how its efficiency might be increased and its economic and social burdens lessened by the promotion of the health of industrial workers, the improvement of their physical environment at work, the anticipation of industrial diseases, and research in their amelioration and neutralisation

(c) *Medical service and hospitalisation*—that is, the ment of the sick It is too often forgotten that this of medicine, which today occupies most of the activitie the profession and the interest of the people, is of humanitarian and public value than the prevention of sickn Such a committee would advise the Government on provision and maintenance of a national organisation render to every individual in the state all necessary med services, domiciliary and institutional

2 *An Imperial Medical Council*, advising the th fighting forces and the Colonial Office on med problems affecting their services and coordinating th from the professional point of view There should the closest liaison between, if not amalgamation these four services If the administrative interdep mental difficulties could be overcome, wasteful ov lapping would be done away with, and the rela isolation of each would be abolished The indivi deficiencies in professional opportunity in each wo be compensated, so that, with the limitless fields colonial medicine and hygiene in front of it and research facilities and encouragement of the acade behind it, such a consolidated service ought to incr immeasurably its attractiveness to potential recruit ment and thereby its usefulness to the communitie would serve and to the state

3 *An International Medical Council* —For ma years German influence and thought has dominated an almost exclusive degree the professional outlook Western, Northern and Southern Europe, and to a degree—but still effectively—in most other countrie the world, a position which was quickly regained a the last war and exploited for political ends This due not so much to professional excellence or origina as to organisation at home and abroad, and the con of medical literature In the chaos, which will fol the cessation of hostilities in Europe, this dominance Berlin must never be allowed to reassert itself, but alternative must be offered The obvious alternati London, and fortunately we have in this coun today, looking for a leader, notable medical represen tives of many European countries Then and th peoples' response to a British lead would be enthusias The international medical council should therefore m plans now, in conjunction with Allied representati for instituting, under the ægis of the academy, International Centre of Medicine Its immediate p pose should be to formulate a policy for the effect rehabilitation of the broken medical organisation culture of the overrun regions of Europe and Asia, would probably have more humanitarian and polit value than any other postwar measure Its long-te purpose should be to assume responsibility for creation of an international centre of research learning, the maintenance of liaison with foreign unive ties by lectureships and otherwise, the conduct international congresses, the publication of stand medical literature in foreign languages, and the orga tion of research to elucidate medical problems in fore lands

4 *The Medical Research Council*, exercising a stimul ing influence on research It would continue functions of the present body with considerably la *financial resources than are available* to it in peace-ti coordinating therewith other sponsors of research in country and extending it abroad, actively stimulat and assisting the advance of medical knowledge to fullest degree It would, moreover, have the advanta of close association with a hospital peculiarly adap for this purpose

5 *Professional Councils (Royal Colleges, &c)* acting advisory professional bodies and controlling th specialties, each retaining its individuality, but gain the advantage of mutual support and coordinati With these might well be included the Royal Society Medicine for its social facilities as a professional meeti ground and its library

6 *A Council of Medical Education*, advising genera on this subject and, in association with the universi assuming particular responsibility for creating, out the scattered arrangements at present available London, a new organisation for postgraduate teachi with a cc

THE WAR AND SCHOOL-BOYS' FOOD

E M. WIDDOWSON
BSC, PH D LOND

R A McCANCE
MD CAMB, FRCP

(*From the Department of Medicine, Cambridge*)

DURING the years 1936–39 we investigated the food takes of 1000 middle-class children, aged 1–18 years, ing in various parts of the British Isles It was clear om this work that the present rations provide younger it not older children with as much of the rationed ods as they were eating before the war Figs 1 ad 2 illustrate this point They show the average nounts of sugar and jam eaten by boys and girls before e war compared with their present rations The dolescent boy is allowed no more of these foods than s 2-year-old brother, although his calorie requirement is more than twice as great Within the family, no oubt, considerable adjustments take place, by which e older children benefit from the rations allowed the ounger ones, but nothing of this sort can happen at oarding-schools which cater entirely for boys of 13–18, r at this age all demand large quantities of food Something was already known of the eating habits of boys at hese institutions, for the diets at two well-known public chools—let us call them St. Butler's and St Hudson's—ad been studied before the war, and also those of boys t a large secondary school, "St. Woolton's" These chools were in the Midlands or the South of England n the spring of 1942 it was decided to repeat the survey t the three schools, to see how the diets had changed oys of ages similar to those previously studied were hosen, and the investigation was carried out at the ame season of the year Each boy weighed all the ood that he ate for a week Details of the method of nvestigation have already been described (Widdowson 936, Widdowson and McCance 1936) Recipes of ooked dishes were obtained, so that their composition ould be calculated The results of this investigation ave been analysed statistically, and only significant ifferences have been emphasised The number of boys t each school who took part in the investigation was s follows —

	St Butler's	St Hudson's	St. Woolton's
1936–38	14	19	26
1942	10	18	24

Results

RATIONED FOODS

Successful adaptation to any system of rationing and estriction calls for the full use of all the rations It also nvolves increasing the consumption of unrationed foods o make up the deficit in calories caused by the restricted ntakes of rationed foods Lastly, it demands the wise hoice of unrationed foods to make good deficiencies ther than calories

Table I shows the average amounts of rationed foods eaten by boys at the three schools before the war, and the ations at the time the 1942 investigation was carried out It also shows the quantities of rationed foods actually eaten in 1942 The figures for butter and margarine present only the butter and margarine spread on bread, they do not include any fat used in cooking Similarly the values for sugar indicate only sugar taken as such—in tea, on porridge, &c It will be seen that the rationed allowances of meat, fats and sugar are all a great deal less than the amounts that boys at any of the schools were eating before the war On the other hand, they did not eat as much bacon or cheese as they were allowed in the spring of 1942

The boys' consumption of rationed foods in 1942 will be found in columns 5, 6 and 7 It is evident that the boys at St Butler's were making full use of their rations They were getting their quota of meat, bacon, cheese, butter and margarine, and this meant that more bacon and cheese was being eaten at St Butler's in 1942 than had been eaten in 1938 In spite of eating the whole of their butter ration, however, and nearly the whole of their margarine on their bread, these boys had only half as much fat for 1½ times as much bread (table II) as they had before the war

At St Hudson's things were quite different The boys investigated there ate only half as much cheese, meat and bacon as their rations allowed them This seemed an extraordinary thing, but inquiries were made and it seemed that it must have been true It strongly suggests that there was something radically wrong with the buying or catering departments

The boys at both public schools were eating a great deal more than their official jam ration, and the figures for jam and sugar are reminiscent of those obtained by Widdowson and Alington for a group of women in 1941 These women were found to be eating considerably less than their sugar ration and more than their jam ration The conclusion was drawn that they were eating stocks of home-made jam, and that they were saving up their sugar for the next jam-making season That the public-school boy should also do this was unexpected, but inquiries have since revealed that it was indeed the case The boys at St Hudson's, for example, were issued with 5 oz of sugar a week, and 3 oz were retained for cooking Even though 5 oz a week was less than a third of the amount that boys at this school ate before the war, they preferred in 1942 to cut down their sugar still further, and to save nearly half of it to be made into jam at home It is quite clear that jam is a highly prized food in the boarding-school dietary

TABLE I—INTAKES OF RATIONED FOODS
(oz per week)

A = St Butler's B = St Hudson's C = St Woolton's

—	Prewar intakes			Ration at time of 1942 survey	Intakes in 1942		
	Public schools		Day school				
	A	B	C		A	B	C
Butter	10 1	9 2	10 9	2	2 0	2 0	2 3
Margarine on bread	0 0	0 0	0 0	4 (total)	3 4	3 1	3 8
Cheese	0 8	0 7	1 6	3	3 0	1 7	2 3
Sugar *	17 5	16 3	13 5	8 (total)	3 0	2 8	4 3
Jam	11 0	15 2	5 1	4	12 6	8 7	6 6
Rationed meat †	28 4	24 1	20 3	9–18‡	15 5	6 6	19 7
Bacon †	2 2	3 4	2 0	4	3 4	1 4	7 0

* Excluding sugar used in cooking † Raw weight
‡ According to price

At St Woolton's, more meat and bacon were eaten than at either of the public schools, and in fact these boys were eating more than their official ration This was because, besides standing a chance of benefiting from the smaller appetities of younger brothers and sisters at home, 9 boys out of 24 were having dinner at school, 5 days a week, outside their rations The average amount of meat eaten by Wooltonians having school dinner was 23 8 oz (raw weight) a week, whereas boys not having school dinner ate an average of 17 2 oz The official allowance of meat for one school meal is twopennyworth This is equivalent to about 2 oz, so it is more than sufficient to account for the difference between these two average weekly intakes Bacon, however, was not served at any of the school dinners at St Woolton's during the weeks of investigation The large amount of bacon eaten by these boys is almost certainly due to the fact that the bacon ration, more than the ration of any other food, is in excess of younger children's accustomed intakes Fig 3 shows the average amounts of bacon eaten by boys and girls before the war, and it will be seen *that they did not begin to* eat as much as their present allowance till they were 13 years old

MILK

The average amounts of milk, taken as milk or in tea and other beverages, and in puddings, by boys at the three schools before the war and in spring, 1942, were as follows (oz per day)

	St Butler's	St Hudson's	St Woolton's
1936–38	11 8	10 5	14 6
1942	9 6	15 3	18 0

Before the war the boys at the day school had rather more milk than those at either of the public schools

Notes and News

MINESWEEPERS' MITTENS

Minesweepers handle chains and gear, and girls in the balloon barrage service know what damage a guy-rope can do, when dragged through the hands by a high wind Mittens made of string are good to wear for such work, but T J Smith and Nephew, makers of 'Elastoplast,' have found something better than string—the selvedge from crepe bandages This selvedge, which used to be returned to the works to be remade, can be knitted up into neat taut mittens, wonderfully warm and resistant to wet Before the war, Mr H N Smith used to send bundles of this selvedge to a women's voluntary organisation in Hull, which arranged for women home workers to knit it up into bath mats, shopping bags and the like At the beginning of the war this organisation became the Hull Comforts for Services Committee and originated the minesweeper's mitten Now it is producing 5000–6000 pairs a year, and over 50 other knitting parties, mainly of the WVS, are at work on mittens In 1940 about 5000 pairs were made, and in 1941 10,000, the figure expected for 1942 is 20,000 The mittens can be made very quickly according to a standard pattern They are sent, either directly or through the firm of Smith and Nephew, to Royal Naval bases all round the coast from Aberdeen to Plymouth, and to balloon barrage units Letters of appreciation bear testimony to the demand for them, a Manchester gunner, stationed on a moor, and working in the cold till 2 or 3 in the morning, wrote "I was always taught as a boy, 'Ask and you will receive,' so I'm just asking and hoping to receive"

University of Oxford

In a congregation held on Nov 21, the following degrees were conferred —

DM —H W Davies, T W Lloyd (in absence)
BM —C O Carter

Medical Honours

The following awards to medical men have been announced

DSC —T/Surgeon Lieutenant A D Bone, MB LOND, RNVR, and Surgeon Lieutenant S A C Watson, RANR

MC —Captain R D I Beggs, MB CAMB, RAMC, and Captain R P Lawson, MB LOND, RAMC

Shortage of Tuberculosis Nurses

The *Liverpool Post* for Nov 25 reports that at the annual meeting of the Liverpool Hospital for Consumption and Diseases of the Chest Mr E Otho Glover, who presided, said that the shortage of nurses was a continuing handicap to their work They could take at least forty more patients at their Delamere Forest Sanatorium if they could get the necessary staff

Royal Society of Medicine

On Tuesday, Dec 8, the section of therapeutics and pharmacology of this society will meet at 2 30 PM to discuss the ætiology of erythroblastosis fœtalis and certain hæmolytic transfusion reactions, with special reference to the Rh factor The openers will be Dr P L Mollison and Dr G L Taylor On Dec 9, at 2 30 PM, Mr E T C Milligan will deliver his presidential address to the section of proctology He will speak on the surgical anatomy and disorders of the perianal space The clinical section will meet on Dec 11, at 2 15 PM, at St Thomas's Hospital, S E 1

Saved by Chemotherapy

Speaking at a meeting of group representatives of the Hospital Saving Association on Nov 29, the Minister of Health said that in the 1915–17 epidemic of cerebrospinal fever two out of three cases were fatal With the help of sulphapyridine today four out of every five patients recovered Mr W J Martin, PhD, of the Medical Research Council, had estimated that during 1939–41 the drug had saved the lives of 10,000 men and women suffering from this disease and probably 7500 more lives from pneumonia "So, taking only two diseases," Mr Brown added, "a single drug has saved more lives than the Nazi war machine was able to destroy in the Battle of Egypt"

Appointments for Outpatients at Charing Cross

From Dec 1 an appointment bureau for outpatients will be open at this hospital from 9 AM to 5 PM Doctors are invited to telephone or write for appointments, and the public also may write for an appointment or make personal application at the hospital

Medical Casualties

The following IMS casualties have been announced

Died —Lieut Colonel W P Hogg, MB ABERD, and Lieut Colo Sukumar, FRCSE

Prisoners of War —Lieutenant B I Evans MRCS, T/Lie Colonel G F Condon, LRCPI and T/Major S G O'Neill, LM DUBI

Royal Faculty of Physicians and Surgeons of Glasg

Dr Donald Hunter will deliver the Finlayson lecture in hall of the faculty, 242, St Vincent Street, Glasgow, on W nesday, Dec 9, at 4 PM His subject will be generali diseases of the skeleton

Medical Society of London

On Monday, Dec 7, at 4 PM, at 11, Chandos Street, W Prof F Wood Jones, FRS, will deliver the Lloyd Robe lecture to this society He will speak on human progress biological theory

Pharmaceutical Society of Great Britain

At 2 30 PM on Thursday, Dec 10, at Friends House, Eus Road, London, N W 1, Mr R Melville, PhD, will delive lecture to this society on medicinal indigenous plants

Chadwick Lecture

On Tuesday, Dec 8, at 2 30 PM, at 26, Portland Pl London, W 1, Dr W Norwood East will give a Chadw lecture on the differentiation, prevention and treatment antisocial behaviour disorders

Distribution of Cod-liver Oil and Fruit Juices

Only a comparatively small percentage of the child eligible for vitamin supplements are at present receiving th and the Ministers of Health and Food are organising intensive publicity campaign to impress upon mothers importance of these preparations for the health of child especially during the winter months The supplements to be on sale at every maternity and child welfare cen Cod liver oil and orange juice are shortly to be made availa for expectant mothers on the same terms as for the unc fives

---

The fact that goods made of raw materials in sh supply owing to war conditions are advertised in t paper should not be taken as an indication that they necessarily available for export

---

Infectious Disease in England and Wales

WEEK ENDED NOV 21

Notifications —The following cases of infectious dise were notified during the week smallpox, 0, scar fever, 2914, whooping-cough, 1246, diphtheria, 10 paratyphoid, 5, typhoid, 6, measles (excluding r ella), 8816, pneumonia (primary or influenzal), 6 puerperal pyrexia, 137, cerebrospinal fever, 68, pol myelitis, 15, polio-encephalitis, 1, encephalitis le argica, 2, dysentery, 117, ophthalmia neonatoru 83 No case of cholera, plague or typhus fever w notified during the week

The number of civilian and service sick in the Infectious Hospi of the London County Council on Nov 18 was 1835, includ scarlet fever, 693, diphtheria, 256, measles, 214, whoop cough, 151, enteritis, 74, chicken pox, 50 erysipelas, mumps, 25, poliomyelitis, 5 dysentery, 48, cerebrospinal fe 3, puerperal sepsis, 19, enteric fever, 5, german measles,

Deaths —In 126 great towns there were no deaths fr enteric fevers, 2 (0) from scarlet fever, 7 (1) from measl 9 (1) from whooping-cough, 26 (3) from diphther 57 (10) from diarrhœa and enteritis under two years, a 21 (1) from influenza The figures in parentheses those from London itself

Liverpool, Sunderland and Birmingham each reported 3 dea from diphtheria

The number of stillbirths notified during the week w 188 (corresponding to a rate of 32 per thousand to births), including 21 in London

TYPHUS IN GALWAY

Of the 13 cases of typhus which occurred between Oct and Nov 18 in the Spiddal dispensary district, 9 were children under eighteen years The source of the outbrea Dr C F McConn tells us, was found to be the househo which originated a much more severe epidemic in 1903- The mode of dissemination being through the school hou children were primarily affected and adults only secondari In all the affected children the disease was of a mild type, the adults it presented the typical appearances There has far been one death, and the epidemic is now apparently und control The area has been closed, all migratory labo stopped, fairs banned and schools closed diets If rationing has meant a reduction in meat, then war-time diets might be expected to provide less *animal* protein The intake of animal protein had fallen at both public schools, but this was partly their own fault, and whether it matters is an open question Even war-time diets are mixed diets, and the assortment of amino-acids derived from the extra bread and vegetables may be as good for growth as those obtained from animal protein The average intake of animal protein at St Woolton's in 1942 was not much lower than the intake at that school had been in 1938, but here again boys having school dinner were weighting the figure Boys partaking of school dinner had 52 g animal protein a day, the others had 40 g

It may seem a little surprising that the boys were getting so much fat It must be remembered however, that they were consuming more cakes, biscuits, milk and cheese in 1942, and the fat in these almost made up for that lost by the restricted intakes of butter, margarine and meat

Carbohydrate intakes had changed very little, though they were somewhat higher at all three schools than they had been before the war Bread, oatmeal and other starchy foods had replaced the sugar of prewar days

The average calcium intakes were higher than they used to be at each of the three schools, but the increase at St Butler's was not statistically significant Milk and cheese were responsible for the change at the other two schools There was little alteration in the amounts of phosphorus ingested The diets contained a little less iron in 1942 at the two public schools and more at the day school National wheatmeal bread was not made compulsory till the 1942 survey was almost completed, and most of the bread eaten was white Since the introduction of the National loaf, the iron intakes will have increased by about 3 mg a day at all three schools.

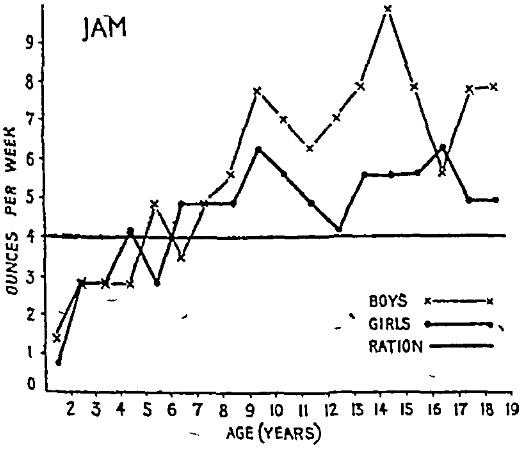

Fig 2—Prewar intakes and 1942 ration of jam

VITAMIN INTAKES

The figures for vitamins in table III are only approximations, but they give some idea of dietary trends Vitamin A and carotene have been given separately because of the difficulty of assessing one in terms of the other The figures for vitamins A and D should be regarded with great caution, for if liver is served to a few of the boys once during the week of investigation, as was the case at St Hudson's in 1936, or if herrings happen to be used, then the average intakes of vitamins A and D for the whole group appear to be very high

The war had made little difference to the intakes of vitamin B_1, but the change to National wheatmeal bread will have increased the intakes by about 110 international units a day

In prewar days one of the most striking differences between the diets of the boys at the three schools was that the day-boys had 50% more vitamin C than those at either of the public schools This was because the day-boys had more fruit and vegetables (see table IV) More than half the public-school boys had less than 30 mg ascorbic acid a day

In spring, 1942, boys at all three schools were of course affected by the shortage of fruit Three boys at St Hudson's and one at St Woolton's had some raw apples during the week of investigation The other 48 had no raw fruit at all Furthermore, raw salad, which had never been very plentiful at the public schools, even before the war, did not appear at either of them Ten boys at St Woolton's had small portions during the week of inquiry The consumption of cooked green vegetables had also fallen off a great deal, and they were never on the menu at St Hudson's As has already been seen, the boys at St Butler's and St Woolton's had increased their consumption of potatoes, the boys at St Hudson's had not The result of all these changes was a smaller intake of vitamin C at each of the schools, and at St Butler's and St Hudson's the average amounts in the diets were 19 and 15 mg a day respectively Before the war the Technical Commission (1938) recommended that all adults should receive 30 mg ascorbic acid daily and that growing children should receive more This may be an over-estimate of the vitamin C requirements (Fox and Dangerfield 1940), but no-one could view with complacency a group of growing boys with an average daily intake as low as 15 mg, even for part of the year

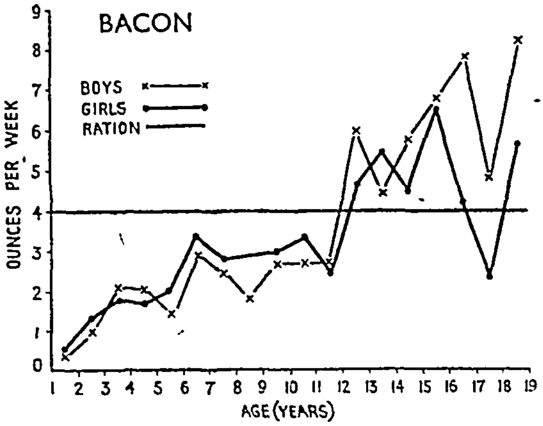

Fig 3—Prewar intakes and 1942 ration of bacon

Comments and Suggestions

If generalisations may be made from the limited data available, the diets of secondary-school boys living at home tend to be better today than those of boys at public schools This is not altogether the fault of the public schools, for they have no extra rations for school dinners, and there is every reason to believe that some of them are feeding their boys as well as they can with the rations at their disposal There is, however, positive evidence that two schools are not, and this may be true of others

TABLE IV—INTAKES OF RAW FRUIT AND GREEN VEGETABLES (oz per week)

—	St Butler's		St Hudson's		St Woolton's	
	1937	1942	1936	1942	1938	1942
Raw fruit	15 2	0 0	12 6	3 2	21 4	0 6

Cooked green veg	7 8	1 5	3 1	0 0	13 5	6 3

All these investigations were carried out in the spring

Schools *must* give boys the rations to which they are entitled The Ministry of Food cannot be expected to allow boarding-schools extra rations until they make full use of those that are already available There is no doubt that at some boarding-schools the staff are being fed better than the boys They have the same meal as the boys midday, and are then supplied with dinner in the evening This probably means that they are being fed from the boys' rations

The Board of Education (1942) has recently issued an excellent pamphlet showing clearly the amounts of rationed foods to which school boarders are entitled It also suggests the quantities of unrationed foodstuffs that should be used. It is interesting to note in this connexion that the suggested potato allowance is 8¾ lb per head per

Many of the boys at St Woolton's were receiving ⅓ pint of school milk a day; those at the two public schools were not. Since the time of the pre-war survey the country has become much more milk-conscious, and this is reflected in the fact that, in spite of restrictions, the milk intake was higher at St Woolton's and St Hudson's in 1942 than it had been in 1936–38. In order to appreciate the significance of the 1942 intakes, the milk allowances for all school-children, whether boarders or day pupils, must be borne in mind. First, they have a priority "household" allowance of ½ pint a day, and in addition, they are entitled to at least ⅓ pint of "school milk" a day, making a total of ⅚ pint or 16.6 oz on 5 days during the week. The average milk allowance over the whole week, therefore, is 15 oz a day. The boys at St Woolton's were clearly getting all their allowances. Those having school dinner were receiving extra milk in puddings, and they were getting more (average 22.5 oz a day) than those having dinner at home (average 15.3 oz a day).

At St Hudson's the boys taking part in this investigation all came from one house, and they were receiving 15.3 oz a day. This probably overstates the milk consumption of the school as a whole, for, although all boys had their meals together, the ordering of school milk was in the hands of the housemasters. In this particular house all boys had school milk. In some of the others they did not.

St Butler's was not taking advantage of the "milk in schools" scheme. Hence, boys there were only getting ⅔ as much as boys at St Hudson's, and they were, in fact, having less than half a pint a day. Inquiries have shown that St Butler's is not the only public school which omitted to take the "school milk" to which it was entitled in 1942. These schools possibly regard the "milk in schools" scheme as a charitable enterprise which it is beneath their dignity to accept.

CALORIES AND UNRATIONED FOODS

Before the war the rationed foods set out in table I supplied a boy at each of the three schools with an overall average of 950 calories a day. In the spring of 1942 a boy at St Butler's obtained an average of 559 calories from these foods; one at St Hudson's could only count on a meagre 395 calories a day, but a Wooltonian got 612 calories out of them. Furthermore, in 1942, boys were not getting the calories to which they were accustomed before the war from unrationed foods such as fruit fish, which have now become scarce. They were suffering a reduction of calories from the restricted fat and sugar for cooking. Were they making good deficit, and if so, how? Table II answers both questions. In previous tables the results for all between 14 and 18 years have been averaged, but, the maximum calorie requirement is not reached till years, comparisons have here been limited to boys similar ages.

It will be seen that the calories had not fallen. Thus the principle first enunciated by McCance and Widdowson (1941), after an experimental study of rationing, was confirmed. They laid it down that if healthy active people were deprived of sources of calories to which they were accustomed, appetite and instinct would drive them to make good the loss by eating more of the unrationed and plentiful foods. The boys at all three schools were now eating more bread, more root vegetables and more cakes than boys of a similar age had eaten before the war. The public-school boys were eating more biscuits and porridge. They should all have been eating more potatoes, and an increase in consumption which was statistically significant-had in fact taken place at St Butler's and St Woolton's. At St Hudson's, however, the average amount of potatoes eaten in 1942 was within 2 oz a week of the amount eaten in 1936. Shortage of labour was partly responsible, for it is of course easier to provide more loaves of bread than to peel and prepare more potatoes and to serve them twice a day instead of once. Be that as it may, an average potato consumption of less than 6 oz a day by 14-year-old boys in the third year of the war needs a great deal of excusing. Boys like potatoes and will eat them if they are provided. The small helpings of potatoes are the one object of criticism in the school dinners provided at St Woolton's. The average portion weighed about 3 oz. It was noticed, however, that boys who had had dinner at school during the week would eat 12 oz or so of potatoes for dinner on Saturdays and Sundays.

A serious reflection on the catering arrangements at the two public schools was that the boys should be buying in the tuck-shop, or having sent from home, more cakes and biscuits than they were before the war.

Sweet rationing was not in force at the time of the 1942 survey, but a ration even of 4 oz a week will have restricted the consumption of sweets at the two public schools and will have forced the boys to make good still more of their calories from unrationed foods.

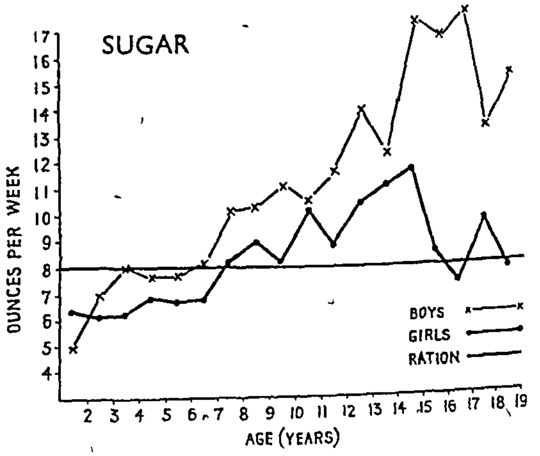

Fig. 1—Prewar intakes and 1942 ration of sugar

CHEMICAL COMPOSITION OF THE DIETS

Table III shows the average amounts of protein, fat, carbohydrate, Ca, P, Fe, and vitamins A, B_1, C and D in the diets of the boys at St Butler's, St Hudson's and St Woolton's before the war and in spring 1942. As in table II the comparisons have been limited to boys of similar ages.

There has been no significant change in total protein consumption. This bears out the finding of McCance and Widdowson (1941), confirmed by Widdowson and Alington (1941), that war-time diets are *not* low-protein

SUMMARY

The nutritional state of 2037 school-children from Oxfordshire homes in city and rural areas, examined in December, 1939, has been compared with that of 499 of the same children who were examined again in February, 1941, and with that of 981 of them examined in June, 1942 In the different age-groups, the nutrition of only 4–13% was classed as subnormal, in 87–96% it was classed as good or excellent

In general the city children appeared rather better nourished than the rural children, but the latter showed some improvement during the period under observation

CONTROL OF PULMONARY TUBERCULOSIS IN INDUSTRY

L. BANSZKY M D BERLIN, L M S S A
MEDICAL OFFICER TO PHILIPS RADIO FACTORIES

AT the time when mass radiography is in the public eye and being introduced as an essential part of medical examination in the Services and industry, it may be of interest to show the results of those large-scale radiological examinations which have been carried out in England and abroad during recent years.

Braeuning, in Germany in 1928, first reported on mass radioscopy; he examined 4789 apparently healthy people by fluoroscopy Details of this report are not obtainable During the following years several large-scale radiological examinations—all of them by fluoroscopy—were carried out by different investigators on the Continent Table I gives the result of all mass radiological examinations on which I have been able to find reports up to Sept 1, 1942, in different countries The method used, the numbers and occupations of those examined and the results as stated by the authors are shown The people selected for the earlier examinations came from different age and society groups; they included children, university students, soldiers, policemen and industrial workers, but since most of them were male, no definite conclusion about the sex-incidence of pulmonary tuberculosis could be drawn from the figures

The first systematic radiological examination of the chest of industrial workers was undertaken in 1932 by Burger in Holland, when the Philips Radio Works in Eindhoven introduced the fluoroscopic examination of the chest of employees as part of the routine medical examination before starting work and a periodic repeat-screening of employees at an interval not exceeding 1¼–2 years But apart from X-ray examination of new entrants and suspects under observation for pulmonary tuberculosis, more ambitious schemes (such as the periodical screening of contacts of tuberculous subjects and of school-children in Philips' schools) have been put into practice, so that from 1932 to 1940 over 100,000 screenings were carried out in Eindhoven Burger (1935–38) and van Weel (1935) have published the result of these screenings in new entrants between 1932 and 1938

Routine radiological examination of new employees was started at the English branch of the Philips radio

week Allowing for waste, this comes to 16 oz a day Much greater use should certainly be made of potatoes, and they should be served at least twice a day It is realised that the domestic staff and kitchen equipment at many boarding-schools are inadequate Some staffs are catering for an evacuated school as well as their own, but in spite of these difficulties it seems that better food might in many cases be served Menus have been obtained from public schools other than the two investigated here, and some show a singular lack of imagination and adaptation to war-time conditions At St Hudson's, breakfast and dinner were reasonable meals, but tea often consisted of bread, margarine and meat paste, and nothing whatever was provided during the evening Potatoes were not often served at any time other than dinner, and no cooked cheese dish ever appeared A greater variety of dishes should be introduced, and much more use of vegetables, fresh and dried, should be made Not only would this add variety and interest to the food, but the intakes of calcium and vitamins A and C would be increased There should be close cooperation between the garden and the kitchen During war-time, at any rate, some members of the domestic staff should remain on duty during the summer holidays, to store and preserve the garden produce At one school the entire crop of tomatoes grown in the school garden had to be given away, as the school was closed down when they ripened and there was no-one available to deal with them

Large institutions usually buy their meat as whole carcasses Where this is done, there should be an adequate supply of fat to give dripping for breakfast or tea at least once a week, and still to leave enough fat for frying Most boys are fond of dripping and fried foods, but they dislike fat meat Instead of serving meat with most of the fat attached, the fat should be removed beforehand, rendered down, and used for frying potatoes and other vegetables

Finally, the boys themselves must be taught to appreciate the gravity of the food situation There can be few boys of public-school age who are not aware of the shortage of shipping and the need for economy in the use of fuel If food designed and fit for human consumption is relegated to the swill bin, just so much of our effort is wasted These facts should be pointed out to them anew, in relation to their own dinner-plates The boy who rejects good food is as much the Führer's friend as any brown-shirted member of the Hitlerjugend, and should be told so

Summary

Individual dietary surveys were made in the spring of 1942 on boys at two public boarding-schools and at a large secondary day-school The data have been compared with the rations in force at that time and with the diets of boys at those schools before the war

Rationing has reduced the calories which the boys were in the habit of obtaining from meat, fats and sugar At all three schools, however, the total calorie intakes have been maintained at their prewar levels by an increased consumption of bread, oatmeal, cakes, biscuits and root vegetables At two schools the potato consumption had also increased, at one it had not

One of the two public schools was not supplying the boys with their full ration of meat, bacon or cheese The other was not taking advantage of the "milk in schools" scheme

The diets of the boys at the secondary school were better than those of the boys at either of the public schools in that they provided more potatoes, more green and root vegetables, and more meat and bacon

All the diets contained as much protein, Ca, P, Fe and vitamin B_1 in 1942 as they had done in prewar days The public-school diets in 1942 provided very much less animal protein and vitamin C than they had done before the war or than the diets of boys living at home provided in 1942 The average vitamin C intake at one public school was only 15 mg a day

Even if boarding-schools make full use of all their rations, boys at day-schools must be considered to have an advantage over boarders, partly because boys living at home are able to benefit from the rations allowed their younger brothers and sisters, and partly because they can have dinner at school, 5 days a week, outside the rations

Continued at foot of next column

NUTRITION OF OXFORDSHIRE IN WAR-TIME

DAGMAR C WILSON
M D GLASG, M R C P, F R C O G, D P H
WOMEN'S MEDICAL SERVICE, INDIA (RETD)

In December, 1939, records were obtained of the nutritional state of 3050 children whose homes were in Oxfordshire They were divided into three groups, (A) aged 6–7, (B) aged 10–11, (C) aged 13–14, and were examined in 41 different rural places and 19 Oxford city schools Evacuees were carefully excluded from this survey Fourteen months later the same rural schools were revisited[1] and the children examined again, they did not show any signs of increasing nutritional deficiency, and no deterioration in the state of nutrition as assessed by the same observer Some degree of deficiency of the vitamin-B_2 complex had been present during the period of observation as indicated by 15 cases of angular stomatitis (cheilosis)

In June, 1942, the original Oxfordshire rural and Oxford city children were examined again, of whom 981 were traced, 526 rural and 455 urban The same nutritional tests were applied as already reported for the previous surveys *The comparative results are summarised in the* table Too few of the 1013 children in group C, aged 13–14 in 1939, remained at school to permit of comparison In the rural areas there was a significant improvement in the children's nutrition Sufficient school milk was now available, and many schools were providing dinners The results of home inquiries indicated in most cases a more regular source of income owing to war-time employment and allowances Many families had increased their cultivation of vegetables, and others were keeping poultry Rural families tend to go early to bed and double summer-time did not appear to lengthen unduly a child's day In places where school dinners were not yet arranged or had only recently been introduced 5 cases of cheilosis were seen There was a decrease in the incidence of rickets in rural areas which may be explained partly by the increasing age of the children, but also by the widespread introduction of school milk

The nutrition of Oxford city children, originally rated higher than that of the rural children, had remained at about the same level as in 1939 Though parents complained of shopping difficulties, the available facilities for school dinners were often not utilised if the meals were served in some place other than the child's own school Teachers considered that double summer-time had adversely affected the hours of sleep of the younger children The only urban case of cheilosis was in a boy from a good home whose sister was well nourished, and was due to defective absorption

In view of the disturbance of the natural ossification of the spine spondylosis deformans which has been found to be fairly common among some groups of English children,[2] the presence or absence of spinal dorsal curvature associated with the mottled enamel of dental fluorosis was noted Among rural children there were 18 such cases in group A and 56 in group B, in the city children there was one case in group A and 4 in group B Suggestions were made for remedial treatment ion require special consideration, I re-examined patients till working after at least 3 years in the factory During he 3 years they were not allowed to work on fumy or hemical processes or in hot atmosphere, but their working hours were not shortened Of the original 244 cases 1 (35 6%) were still in the factory after 3 years, 28 being nen and 53 women Of these, 8 (3 men and 5 women) howed signs of activity in the lesion on repeat-screening nd required monthly observation—that is, 10% of the vhole group Whether this was due to new exogenous nfection or to an activation of a previously inactive rocess, I cannot say

---

[1] Wilson, D C *Lancet*, 1941, ii, 405

[2] Kemp, F H, Murray, M M and Wilson, D C *Ibid*, 1942, ii, 93

The incidence of active (including open) tuberculosis ver the 5 years averaged 0 5% in Mitcham, and the umber of employees sent for treatment on account of ctive tubercle was 60 (16 men and 44 women) In 53 ases (13 males and 40 females) the diagnosis of active lisease was made after the first examination, including adiography, sedimentation-rate, blood-counts and putum test, in 7 (3 men and 4 women) the diagnosis vas made after the employee had been under observation or a while

In 34 (10 men and 24 women) of the 60 active cases the lisease was open (55%) The presence of Koch's bacilli vas demonstrated in the sputum, the gastric contents vere not examined

That there is urgent need of a uniform national scheme or tracing and controlling pulmonary tuberculosis is hown by the fact that during the 5 years 41 employees (17 men and 24 women) left the factory while under bservation for active tuberculosis and were lost sight f, among those were 3 men called up as fit for military ervice

SUMMARY

The results of mass radiography in 37 reported series of cases are tabulated

Fluoroscopic examination of industrial workers in England during 5 years showed an incidence of active pulmonary tuberculosis twice as high in women as in men (0 63% women, 0 33% men) When incidence-rates of tuberculosis in industrial workers in two branches of the same factory—one in England and another in Holland—were compared, a higher rate in women was found in England and a higher rate in men in Holland

Comparing five branches of the same factory (one in England, three in Holland and one in Belgium), the highest incidence for active tuberculosis was found in Belgium and the next highest in England The incidence of active and doubtful tuberculosis is exactly the same in the English and two of the Dutch branches, but double that rate in Belgium and slightly lower in one Dutch factory

Of active cases who had had sanatorium treatment 34% returned to work in the Eindhoven (Dutch) branch and 15% in the English branch The relapse rate among treated cases after return to factory work was 27% in Eindhoven and 22 2% in Mitcham

Some patients with doubtful lesions developed signs of activity while working in the factories, while others showed improvement In Eindhoven, the percentages of those who deteriorated ranged from 7 to 9 5 during the years 1935–38 ; in the English factory the average figure over 5 years was 5 6% Improvement in symptoms was noted in percentages of cases ranging from 7 to 40 in Eindhoven over the same 4 years, and the average English figure over 5 years was 10%

COLD IN THE TREATMENT OF DAMAGE DUE TO COLD

RAYMOND GREENE,[*] D M OXFD
PHYSICIAN, EMERGENCY MEDICAL SERVICE

TISSUES damaged by cold may be regarded as being in one of three states

1 *The State of True Frostbite*[1]—The tissues in this state have generally been regarded as "killed" by cold, some investigators regarding the death as due to irreversible physico-chemical causes and others to destruction by ice crystals Others have blamed thrombosis for the necrosis which occurs, but though thrombosis may occasionally be seen it is a secondary phenomenon and not the cause of death The changes are really due to stasis The capillary walls, weakened perhaps by nervous causes, by crystal formation or by anoxia, become, during the thaw, freely permeable to plasma, but only in extreme cases to red cells The fluid part of the blood leaves the particulate cells stranded in the vessels, which become silted up Intravascular agglutination takes place, followed by asphyxia of tissues The living body then casts off the damaged member It is often forgotten that gangrene does not develop in the dead Whether from frostbite, thrombosis or embolism, necrosis is a vital process

Solidification is not the essential sign of true frostbite, or death of the tissues its invariable sequel I have many times seen a nose grown suddenly white in a high wind and by promptly covering it with my hand prevented further harm In a recent investigation I have more than once accidentally frozen my finger tips solid without permanent damage The tails of mice frozen hard are not entirely lost, the final destruction depending on the time of freezing The legs of cats may be frozen so hard that they emit a ringing note when tapped with a chisel, yet recover with no loss of tissue In these examples, there was not time for the essential capillary damage to occur.

In the field such damage occurs very quickly, and no measure other than the instant application of gentle warmth no greater than that of the human body can affect the issue The tissues are damaged beyond repair and will be cast off Treatment can be directed only to the avoidance of further damage and of sepsis

2 *The State of Chilling*—Even when the cold has been so great and has lasted so long that true frostbite has occurred, there lies between the doomed tissues and those untouched by cold an area in which the damage is less severe and necrosis not inevitable When the cold has been slight, the whole tissue may be in this state, a condition known clinically as trench-foot and immersion-foot The essential damage in this area is also in the capillaries, but the loss of fluid from them is less massive and silting up does not take place Nevertheless, though the circulation continues it is seriously handicapped The sudden strain which falls on the capillary walls when, during thaw, the arterioles relax, produces an œdema which, conditioned by the high pressure at the arterial end of the capillaries, compresses them at the lax venous end A mild anoxia follows, which, added to that already produced by vasoconstriction, may have serious consequences The clinical condition is very like that seen in senile diabetes, in which long-continued mild anoxia, due to arteriosclerosis, leads to demyelination of the peripheral nerves and to consequent "neu-

[1] The evidence for statements in this paragraph is in course of publication

factory at Mitcham in 1934 These examinations consisted in the first 2 years of screening only, but from 1936 onwards facilities for full-size radiograms, sedimentation-rate estimation, sputum test and blood-counts were provided for all suspected cases The percentage findings are shown in table II

These figures show that the incidence of active and open pulmonary tuberculosis among a group of women industrial workers in England is nearly double that among men doing the same work (men 0 33%, women 0 63%), and when all active and inactive tuberculous processes are included about 25% higher than in men (men 3 5%, women 4 5%)

To compare the incidence of pulmonary tuberculosis in employed and previously X-rayed workers with the rate in new entrants, repeat-screening was undertaken in Philips factories both in Eindhoven and Mitcham Figures of these repeat-screenings are available from Eindhoven for the years 1936, 1937 and 1938 and from Mitcham for 1936 only, because labour problems during the following years prevented any repeat screening on a large scale The Eindhoven figures for 1936–38 inclusive are given in table III

TABLE II

—	% of all entrants	% of men entrants	% of women entrants
A Lung affections (active, open, doubtful, inactive, cyst, bronchiectasis, &c)	4 1	3 5	4 5
B Active and open	0 51	0 33	0 63
C Doubtful (under observation for activity)	0 58	0 63	0 53
D Inactive	2 8	2 4	3 0

The comparatively small percentage of active cases found among new entrants is explained by the fact that many of those classed under this heading in Eindhoven had been employed before by the same firm, but had been temporarily out of work on account of trade fluctuation These had therefore been previously screened and from the point of view of tuberculosis tracing were a selected group

A comparison has been made of the incidence of pulmonary tuberculosis among new entrants and old employees in the Eindhoven and Mitcham factories The Dutch figures derive from the period 1932–34 and the English ones from 1936, but they throw some light on the incidence of pulmonary tuberculosis in the two countries Table IV shows that in both factories active tuberculosis was only a third to half as common among old employees as among new entrants

TABLE III

—	—	Open (°/₀₀)	Active (°/₀₀)	Doubtful (°/₀₀)
1936	New entrants	0 7	2 4	2 4
	Old employees	0 2	1 3	1 3
1937	New entrants	0 4	3 0	4 0
	Old employees	0 6	2 9	6 0
1938	New entrants	0 3	0 9	5 0
	Old employees	0 2	0 6	4 0

It is noteworthy that whereas in England tuberculosis was commoner among women, in Holland it was commoner among men Thus among new entrants in England the incidence of all forms of tuberculosis was 1 8% for men and 3 2% for women, while in Holland the figures were 2 3% for men and 1 8% for women, among old employees the total incidence in England was 1 6% for men and 2 1% for women, compared with 1 9% for men and 1 5% for women in Holland The preponderance of men in Holland is found only in the doubtful and open groups, in the active group, as table IV shows, women preponderate slightly

Fluoroscopic examination of new entrants in the various branches of the Philips factories in 1938 showed the incidence of pulmonary tuberculosis to be as shown in table V

TABLE IV—PERCENTAGE INCIDENCE OF PULMONARY TUBERCULOSIS AMONG NEW ENTRANTS AND OLD EMPLOYEES AT THE MITCHAM AND EINDHOVEN FACTORIES

—	New entrants			Old employees		
	Total	Men	Women	Total	Men	Women
Open tubercle—						
Mitcham	0 2	0 0	0 3	0 2	0 1	0 3
Eindhoven	0 3	0 4	0 01	0 1	0 1	0 1
Active tubercle—						
Mitcham	0 8	0 3	1 2	0 2	0 1	0 3
Eindhoven	0 9	0 7	1 0	0 4	0 4	0 5
Doubtful—						
Mitcham	1 6	1 4	1 7	1 4	1 4	1 5
Eindhoven	1 0	1 2	0 7	1 3	1 4	0 9

As far as active tubercle goes, the Brussels branch shows the highest and the Mitcham branch the next highest incidence, but taking active and doubtful processes together the Brussels branch has nearly double the incidence of the Mitcham branch (3 6% Brussels, 1 68% Mitcham), but the Eindhoven, Hilversum and Mitcham branches have exactly the same incidence (1 7%) and only Tilbury (Holland) has a lower one

EFFECT OF FACTORY WORK ON TREATED CASES

What percentage of the sanatorium treated workers can take up factory work after completion of treatment, and how many will relapse, even on light physical work and in selected surroundings? In Eindhoven during the years 1932–38 460 active (open and closed) cases were sent for sanatorium treatment, of whom 155 have returned to work (33 9%) In Mitcham during the five years 1936–41, 60 active (open and closed) cases were sent back to their own doctor for treatment (16 men and 44 women) of whom 9 (3 men and 6 women) have returned to work after completion of treatment (15%) Circumstances differ in Eindhoven and Mitcham In a small town like Eindhoven cases can be followed up, but at the Mitcham branch many sanatorium-treated workers moved to different districts or preferred easier occupations than factory work and were lost sight of The Mitcham figures are thus not an accurate example of workers who can take up factory work after treatment, and the Eindhoven ones should be considered as the more reliable of the two

TABLE V

—		Active (%)	Doubtful (%)
England, Mitcham		0 87	0 81
Holland	Eindhoven	0 42	1 3
	Hilversum	0 5	1 2
	Tilbury	0 5	0 5
Belgium, Brussels		1 3	2 3

Burger's figures in Eindhoven during the years of 1936–37–38 for relapses after return to factory work are as follows 1936, 27%, 1937, 26%, 1938, 37% These relapses were seen within 3 years after the quietening down of the lung process In the Mitcham branch of 9 patients who returned to work after treatment during 1936–41, 2 suffered relapse (22 2%) The effect of factory work on doubtful cases (where activity cannot be determined at the first examination and the patient is allowed to work in suitable surroundings in the factory while under observation) can also be shown both in the Mitcham and the Eindhoven records Burger found that doubtful cases changed to active ones in the following percentages 1935, 7%, 1936, 9 5%, 1937, 8 5%, 1938, 7 5% In my cases the average over 5 years was 5 6%

Changes for the better as well as for the worse are to be seen in the same group of doubtful cases Quietening down of doubtful cases with disappearance of all active signs was seen by Burger in the following percentages of cases 1935, 7%, 1936, 35%, 1937, 40%, 1938, 30% I found in Mitcham that an average of 10% of doubtful cases quietened down over 5 years

To determine whether calcified primary processes without any sign of activity found on the first examinaof these conditions should therefore be

Ancient tradition and modern experiment combine to suggest that while the patient himself is kept warm the affected tissue should be cooled , A refrigeration apparatus is described by means of which this object may conveniently be attained

FEBRILE ILLNESS IN SMALLPOX CONTACTS

W F TYRRELL, M B, B SC GLASG, D P H
RESIDENT PHYSICIAN, KNIGHTSWOOD HOSPITAL, GLASGOW

Conybeare (1939) drew attention to a symptom complex which he noted in 7 of 16 smallpox contacts, and which he suggested might be examples of variola sine eruptione More recently Bowe (1942) has reported a febrile illness in 3 out of 7 contacts in explanation of which a similar reason was advanced In Conybeare's cases, vaccinia seemed unlikely since in one of them there had been no recent vaccination It is not clear from Bowe's records whether vaccination was successfully carried out in all of his cases As a rule, however, smallpox contacts are revaccinated at the time of their contact, so that confusion between a reaction to vaccinia and one to variola might well occur

Napier and Insh (1942) have recently reported febrile reactions in 40 out of 92 Glasgow smallpox contacts under their care They decided that 30 of these 40 reactions were due to vaccinia, and 2 to smallpox , the remaining 8, which were difficult to classify, were finally relegated also to the vaccinia group

As a result of the outbreak of smallpox in Glasgow, part of this hospital was set aside for the reception of smallpox contacts , 45 were admitted and were vaccinated or revaccinated after admission Since the rest of the hospital was to continue as an infectious disease hospital, vaccination was offered to all remaining patients, and in the next few days 89 persons were vaccinated with material from the same source as that from which the contacts were inoculated So far as I am aware no-one has previously compared two similar groups of people, contacts and non-contacts of smallpox, vaccinated under similar conditions This paper is an attempt to do so The age-distribution of these two groups is shown in table I

TABLE I—AGE-DISTRIBUTION OF VACCINATED PERSONS

Age group (yr)	Contacts		Non contacts	
	Primary	Revacc	Primary	Revacc
0– 5	4 (2)	1 (0)	10 (6)	4 (3)
6–10	3 (2)	2 (2)	6 (4)	3 (3)
11–15	2 (2)	4 (1)	1 (1)	4 (1)
16–25	3 (3)	8 (1)	3 (1)	4 (2)
25 +	0 (0)	18 (5)	0 (0)	54 (11)
Totals	12 (9)	33 (9)	20 (12)	69 (20)

The figures in parentheses indicate the numbers in the different groups who showed a febrile response

A febrile reaction was observed in 18 (40%) of the contacts and 32 (36%) of the non-contacts , the mean duration of fever (table II) was slightly greater in the contacts, but the difference is not statistically significant

Table III shows the day of onset, after vaccination, of the febrile reaction In the contacts, the mean maximum temperature was 99 8° F , noted on the eighth day , in the non-contacts the mean maximum was 99° F , also noted on the eighth day

TABLE II—DURATION OF FEBRILE REACTION

—	Days						Mean
	1	2	3	4	5	6	
Contacts	8	1	5	2	2	0	2 9
Non contacts	18	5	3	3	1	2	2 1

The symptoms complained of were, in contacts, headache (2) , pain in back of neck (2) , general malaise with syncope (1) In non-contacts they were drowsiness (4) , nausea (3) , abdominal pain, headache, backache, vomiting (1 each) . Two patients, both contacts developed rashes , one a papular urticaria on the groins , the other a macular eruption on the lower abdomen and buttocks One man, a non-contact, had glycosuria for one day

DISCUSSION

The results in the two groups, contacts and non-contacts, vaccinated at the same time with similar material and kept under similar observation, show no significant differences The figures supplied by Conybeare and Bowe (10 of 23 contacts) suggest that the incidence of the reaction described by them is high In observing 45 contacts one might have expected, therefore, to see several examples One of the contacts developed modified smallpox and was removed, so that one can infer that exposure (in some cases of a very close nature) had occurred If the observations of Napier and Insh are considered with mine, out of 137 contacts under close observation not one showed a febrile reaction which, after careful consideration, could be described as variola sine eruptione

TABLE III—DAY OF ONSET OF FEBRILE REACTION

—	Days														Mean
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	
Contacts	0	0	1	1	2	4	1	5	1	2	0	1	0	0	7
Non contacts	0	3	2	5	9	1	3	4	1	3	1	0	0	0	5

The conclusion seems justified that caution must be exercised in accepting alleged cases of variola which show no more than a few days fever with or without subjective symptoms It seems reasonable to expect cases of variola sine eruptione to develop in vaccinated people, by analogy with the results obtained in measles contacts who receive convalescent serum If such reactions do occur, they should be most manifest in the personnel of smallpox hospitals Dr John Watson of the smallpox hospital states in a personal communication that he has not seen any such illness The experience here was that no reaction was seen among the contacts which could not be paralleled in non-contacts vaccinated at the same time

I wish to thank Sir Alexander Macgregor, medical officer of health, for permission to publish these notes, and Dr Thomas Anderson, physician-superintendent of Knightswood Hospital, for his advice

Prof F E Tylecote has been elected chairman of the Manchester public health committee Professor Tylecote was also recently elected president of the Royal Manchester Institution

PADDINGTON MEDICAL SOCIETY —A meeting of this society will be held on Tuesday, Dec 15, at 2 30 PM, at St Mary's Hospital, W 2, when Dr Joseph Whitby will read a paper on neurosis in general practice during the second and third years of the present war ritis " In extreme cases, gangrene may develop In chilled tissues a more severe anoxia is needed to produce gangrene than to produce degeneration of nerves It is in this state that treatment is logically possible

3 *State of Physiological Reaction* —The tissues in this state are responding normally to damage Adaptation has not broken down No treatment is required

PRINCIPLES OF TREATMENT

It follows that we need consider therapeutically only the state of chilling, the state of some of the tissue in frostbite and of all of it in trench-foot and immersion-foot It is traditional that warmth greater than that of the human body is harmful This fact was recognised by Larrey (1812) during Napoleon's retreat from Moscow Smith, Ritchie and Dawson (1915) showed that when damage by cold has occurred water at only 37° C causes rapid œdema or a rapid increase in œdema already present, a fact confirmed by Lewis and Love (1926) I have shown that if the tail of a mouse is frozen almost twice as much tissue is lost if the mouse is held in the hand before a warm fire It is shocking to learn that only last winter patients with frostbite were treated with the electric cradle, mustard plasters and hot fomentations Such treatment is sure to increase transudation from the damaged capillaries by still further increasing arteriolar dilatation In addition, between the part irretrievably doomed to gangrene and the part never endangered there is probably an area striving for life in a state of anoxia Heat to this part will increase its metabolism and its oxygen requirements, and will encourage the growth of bacteria Frost-bitten parts must be kept cool (Greene 1941)

Lake (1917) has shown that the survival-rate of tissue-cultures is greatest between — 5° C (at which temperature they die) and + 5° C (at which point katabolic processes are predominant and harmful metabolites accumulate), the best temperatures being in the neighbourhood of 0° to + 5° C Lambert (1913) found that embryonic chick tissues survived best at + 5° C That blood will survive undamaged at + 2° C for three weeks has become well known since the establishment of blood banks Allen (1939) has shown that tissue necrosis after ligation of a limb is increased by heat and diminished by cold Dickson Wright (1940) pointed out that " a dog's hind limb will stand a tourniquet for two days if the leg is kept just above freezing-point and the leg will be undamaged if the dog's leg is kept ' nice and warm ' the usual stinking gangrene develops and the leg is lost "

The conclusion is obvious Tradition and modern science combine to urge that the frostbitten or chilled limb should be kept at a temperature just above freezing-point Against this might be brought the argument that it is absurd to continue those very conditions which have produced the disorder we are treating The answer is that we are doing nothing of the kind The patient has been spending hours or days in sodden clothing in an open boat or on an inhospitable mountain side His whole body has been chilled, his feet and hands are wet The general chilling has interfered with the physiological reactions to cold (Lewis 1931), the damp, by reason of its thermal conductivity, has augmented a local chilling which the low temperature alone could not have made so lethal The arterial constriction which was the first cause of his injury was produced by the passage of chilled blood through the thermal centre in the thalamus From the time of his rescue, conditions should be otherwise With his whole body at rest in a warm bed, the blood in the carotids will not be at a temperature low enough to excite the thermosensitive area The adrenal medulla will be unexcited by hypothalamic stimuli due either to cold or to emotional stress, and vasoconstriction will be slight or absent But the threatened tissues will be protected by their low temperature from the results of excessive metabolic activity

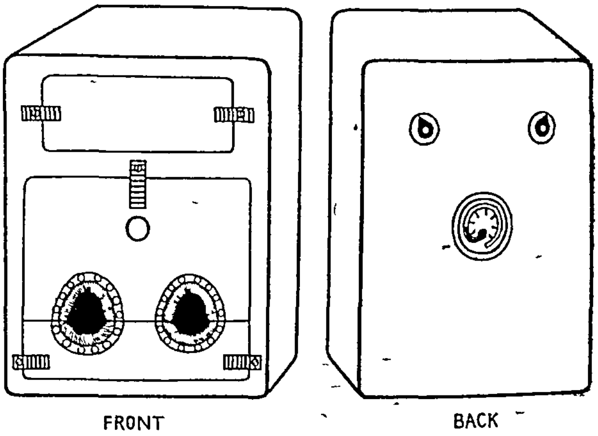
THERAPEUTIC REFRIGERATOR

During the winter of 1941–42, with the cooperation of Mr R J Simpson of the International Refrigerator Company, I designed an apparatus in which I hoped to test the practical truth of this theoretical argument It is shown in the figure

The cabinet consists of an upper and lower compartment In the upper is a metal tray in which solid carbon dioxide is placed The lower compartment opens sections and has two padded apertures for the feet It contains a thermometer which registers dial at the back of the cabinet Air circulates t two flues between the compartments These flues controlled by knobs at the back, by the manipulat which the desired temperature can be maintained operating instructions are as follows

1 Remove top half of front, place patient's feet in with sufficient cotton-wool or bandage round the ankles fill up the padded entrance holes when the cabinet front replaced If the cabinet is needed for only one limb, plug other hole completely with cotton wool or bandage to prevent leakage of air

2 Place two blocks of solid CO_2 refrigerant in tray in compartment—total weight 10–12 lb —each block inside separate canvas bag, the bag being well wrapped around it. To cool the cabinet quickly from room temperature place refrigerant in the tray unwrapped On the second filling, when the cabinet is cool, refrigerant can be economised by placing it in two bags or layers of canvas instead of one



3 See that both air-flues are open and watch carefully as temperature falls When desired temperature is reached close left hand knob (controls downward flue) When temperature rises open it slightly and find point of balance where constant temperature is maintained The right hand knob (controls upward flue) is only for use in emergency if temperature continues to fall and should normally be left fully open

4 When refrigerant has evaporated to 2–3 lb remove the bags and place it directly in the metal tray. If desired the cabinet can be run from the start with 2 or 3 lb of refrigerant placed directly in the tray, but this will necessitate re filling the tray about every six hours The cabinet uses 8–10 lb of refrigerant in 24 hours

It was my intention to test the efficacy of the treatment with the promised collaboration of the RAF Fortunately, I was denied this opportunity, and the apparatus is now described for the benefit of those whose opportunities may be greater In the first instance an attempt should be made to control the experiment by treating only one limb of those who are bilaterally afflicted

In the meantime, Webster, Woolhouse and Johnston (1942) have described their experiences with a method identical in theory but less convenient in practice Using ice-bags or dry cooling by means of a fan sprayed with iced water, they found that the constant burning with bouts of stabbing pain and pins and needles were relieved I have found the same in diabetic gangrene, but from this observation alone it cannot be said that the effect is specific However Webster and his colleagues found in addition that the swelling subsided and the blisters resorbed, and that in six cases of impending gangrene the normal pink colour returned in from 6 to 21 days

SUMMARY

In true frostbite, most of the affected tissue is doomed and no treatment can save it Some, however, is merely chilled and is in the same condition as is the whole affected tissue in immersion-foot and trench-foot The

MEDICINE AND SOCIAL SECURITY

Sir WILLIAM BEVERIDGE in a report which has easily en the best seller of the week has set out to provide ery man with the feeling of security in his daily life ich is essential to full membership of human society, st as it is the biological requirement of the human fant The Ministry of Social Security which he roposes is like the Ministry of Food, directed to the tioning of the necessary things of life so that each is sured a proper share of them It is the consumer *ho is the* object of *ministerial care* , *the* producer *is* ot to be regimented except in so far as his activities re antisocial The elements of a healthy life are part f the make-up of social security, and medicine is the mplement of the healthy life It is one of the major sumptions of the Beveridge plan that there shall be omprehensive health and rehabilitation services for ll who need them The primary interest of the inistry of Social Security will be to find a service hich will diminish disease by prevention and cure , t will not be its rôle to define the working of such a ervice The medical service envisaged by the everidge report will be organised not by the ministry ncerned with social insurance but by departments sponsible for the health of the people Actually Beveridge's conception of the restoration of a sick erson to health as the primary duty of the state ncides with the objects of medical service as prosed by the BMA Medical Planning Commission here is no suggestion in the report of any regimentaon of medicine to this end The plan expresses no pinion on the terms of service and remuneration of ctors of various kinds, of dentists and of nurses, cept in so far as these terms may affect the possility of diminishing and controlling sickness and so ay affect the finances of the Social Insurance Fund The practice of medicine in the postwar world remains to be worked out by those who have been bred in its raditions the doctor-patient relationship remains nimpaired, but its efficacy is to be enhanced an undredfold by the abolition of the want and insecurty which have frustrated the practice of medicine as we have known it The doctor's prescription need no longer be a bottle of physic plus a pious aspiration , it can be addressed to the patient's whole personality When he says "be warmed and fed ' or 'keep an easy mind" or ' you need a change,' these injunctions will have lost their hollow ring It is true that he Beveridge plan expects contributory insurance or medical treatment to cover the whole population, not merely the 90% of the Medical Planning Commission Thus, no-one will be compelled to pay eparately for medical treatment, just as no-one is compelled to pay separately for education But this will not, of itself, put an end to private practice any more than it now does to private schooling And the same is true of provision for invalidity, retirement and dependants

---

VITAMIN C NUTRITION

THERE are four ways of estimating the state of vitamin C nutrition—by a study of the diet, by laboratory tests such as the degree of ' saturation " by functional tests such as capillary fragility, and by clinical tests Examples of the first three types of investigation have lately appeared in these pages, and each has raised fundamental questions of interpretation MARRACK and his colleagues[1] estimated the vitamin in meals at British Restaurants and school canteens, and showed that unless green vegetables are included the amount may be only half the 30 mg widely accepted as the daily requirement Since in many instances very little more of the vitamin is consumed in other meals some degree of deficiency seemed likely At two public schools whose diet was investigated by WIDDOWSON and McCANCE and is reported on in this issue, the average daily intake of vitamin C had fallen from 33 and 34 mg before the war to 19 and 15 mg in spring, 1942 In one of the two schools neither green vegetables nor salad appeared on the menu during the week of investigation, and there was hardly any increase in potato consumption over the prewar figure , only 3 boys had any raw fruit The intake at the day-school was better—32 mg a day—because more potatoes and green vegetables were eaten A fairly accurate estimate of the vitamin C in the recent diet may be obtained by the saturation test It is known that people receiving 30 mg daily show a high excretion of the vitamin after one or two days of test dosing, that people with frank scurvy—i e , receiving very small amounts—respond only after about 7–10 days , and that intermediate responses are obtained when diets contain intermediate amounts of the vitamin MCNEE and REID,[2] using this method, have shown that the diet of some civilian engineers in the autumn and of both Royal Naval ratings and civilian engineers in the spring must have contained much less than 30 mg of the vitamin per day

The importance of the findings by these two methods depends on what one regards as the requirement of the vitamin The League of Nations commission put it at 30 mg daily , BACHARACH and DRUMMOND[3] say that 30 mg is the marginal ' requirement, and many American workers maintain that the optimal requirement is around 75 mg The argument is continually being put forward that the requirement must be lower than 30 mg , since a large number of people who consume much less than this amount are apparently in perfect health Attempts have therefore been made to develop tests which might detect early disturbance of function in such apparently healthy people For vitamin C the commonest functional test is that which measures the fragility of the capillaries GOTHLIN,[4] who first introduced this test, claimed that it was of great value in detecting mild cases of hypovitaminosis C, but different workers have obtained divergent results with it This is partly because of the different techniques used Capillary fragility is determined by applying to the arm either a positive or a negative pressure which will rupture weak capillaries and produce petechiæ, but neither the pressure nor the time of application is

Reviews of Books

Diabetic ABC War-time Supplement

(2nd ed) R D LAWRENCE, MD Aberd , FRCP London H K Lewis Pp 15 9*d*

THE efficient dietetic treatment of diabetics was no easy problem even in peace-time and its difficulty has increased with war-time food restrictions To many doctors and patients, however, the difficulty has seemed greater than it need special rations have been available for diabetics since the beginning of rationing, and if these are properly used diabetic diets of all varieties can be constructed In this small pamphlet Dr Lawrence with customary lucidity shows how this can be done, and in particular how patients who have been using the "line ration" scheme can adapt their dietetic prescriptions of peace-time to the food available in war He also gives much sensible advice about dealing with dangers due to disturbances of routine which nowadays all diabetics must be prepared to face In the interests of both personal and national economy he urges diabetics to change from single-strength insulin to the stronger solutions and to alter the amount of fluid injected accordingly , but desirable as this change is, it should be remembered that serious mistakes have been made, even by veteran patients, in measuring out the same dose of insulin from solutions of different strengths It would have been just as well to warn the patient to ask his doctor to show him how to make the necessary change

Sex-fulfilment in Marriage

E R GROVES, professor of sociology in the University of North Carolina , G H GROVES , C GROVES New York Emerson Books Inc Pp 319 $3

THIS book, despite a certain diffuseness, provides a popular and readable exposition of its subject It offers as the pooled and experienced wisdom of three intelligent people, that the giving out of love and integrity, consideration and understanding must be practised of necessity by both partners, all the time and in all circumstances, if sex is to be really enjoyed and fulfilled Sex is discussed as it affects men and women in health and in mental and physical sickness It is significant of the divorce between sex and birth in our minds at the present time that such a book should not discuss the optimal size of a family, nor the unaccepted truth that sex for a woman is not complete unless it results in childbirth It must be twenty years since Havelock Ellis published *Little Essays of Love and Virtue* (and why have we not had them reprinted as a Penguin ?) , like Ellis, the Groves aim at putting sex at our disposal as a good servant and friend of man but after twenty years it is still, unfortunately, as the good servant and friend of man acquisitive and individualist, and not of man the member of a family and community In common with *Parents Revolt*, by Richard and Kathleen Titmuss, this book recognises that " that by which men live the good life " is Tolstoyan and outgoing in essence, and not Nietzschean and grasping

Essentials of Occupational Diseases

J V REED, MD, FACS , A K. HARCOURT, MD London Baillière, Tindall and Cox Pp 225 25*s*

THIS book deals with the symptoms, diagnosis and treatment of occupational diseases but—strangely—gives no space to the question of prevention The outstanding feature of occupational or industrial diseases is that they can be prevented and even in the first textbook on the subject—Ramazzini's *De Morbis Artificum* published some 150 years ago—the preventive aspect was rightly stressed Reed and Harcourt write ostensibly for doctors who deal with compensation cases in America, where the law differs considerably from ours In the introduction they imply that health risks in a factory are investigated, not by physicians, but by chemists and industrial engineers , and add that information about health risks in a factory is " best obtained from the shop foreman " On the same analogy a works manager having trouble with his machines would do well to call in a doctor The authors lay no claim to originality, except for a few clinical observations of their own, but the sections on carbon-monoxide poisoning and on dermatitis are worthy of study they bear the imprint of much first-hand Some other sections do not show the same

The Premature Infant

Its Medical and Nursing Care JULIUS H HESS, EVELYN C LUNDEEN, RN , London and J B Lippincott Company Pp 309 21*s*

NO-ONE interested in infants can read this vol without being impressed by the wealth of helpful d compressed into it Dr Hess tells us that the mortal *rate in infants in the State of Illinois in* 1930 was while in 1940 it was 35 1 , in Chicago over the same pe it was reduced from 53 4 to 28 8 When we remem that in 1939 in England and Wales the infant mortal was 50, and that this year it is 59, we must feel grav dissatisfied with the state of affairs here His definit has been accepted in this country that " the premat infant is one whose weight at birth is below 5½ lb " traces the physiological development of the infant a gives useful tables of growth A premature infa station is described where the Hess heated bed a many other incubators are used He thinks nursi personnel at such a station should average one for eve 2 or 3 infants Masks, he considers, are of doubtf value ; in fact, he does not advise them for those nursi premature infants It is striking that he advocates very low intake of calories for instance, he suggests tha the average premature infant requires 36 calories per lb body weight Over here practical infant feeders an those accustomed to premature infants recommen 60–70 calories per lb He is careful not to comm himself in supporting lactogenic hormones as stimulant for breast milk, and seems to have little faith in them u to the moment The technique of breast and bottle feeding are faultlessly described Vitamins are giv their full due, and there is a good chapter on hæmorrhag in the newborn The last 90 pages deal with disease which may affect premature infants As an exhaustiv study of the subject the book will be serviceable to al those interested in lowering infant mortality

Pasteurisation of Milk

G S WILSON, MD Lond , FRCP, DPH, professor of bacteriology as applied to hygiene in the University of London at the London School of Hygiene and Tropical Medicine London Edward Arnold. Pp 212 18*s*

THE white paper on milk policy of 1937, with its proposals for a measure of compulsory pasteurisation, and the Milk Industry Bill of 1938 with clauses to implement such proposals, raised high hopes in the medical profession—hopes wrecked by the heavy opposition in the House of Commons At that time the Minister of Health could only plead for further education of public and parliamentary opinion These points are clearly brought out by Sir Wilson Jameson in his foreword to this book Professor Wilson has reviewed existing evidence about pasteurisation, and though most of the facts were accessible to those who really wanted them it is convenient to have all the evidence set out in one volume The exposition too is thorough and lucid The opponents of pasteurisation have concentrated their greatest objection to this process on the ground that, in ways which they have always hesitated to define, pasteurisation damages the nutritive qualities of milk In three detailed chapters the author gives the whole of the scientific evidence and experts will agree with his conclusion that " pasteurisation has no significant effect on lowering the total nutritive value of the milk for the growing animal " The only defect of the book is that too little space is given to the efficient control of the process of pasteurisation The phosphatase test is described and its efficiency indicated, but more might have been said about training supervisors and inspectors of milk plants, and the need for a high standard of supervision Professor Wilson makes good his claim that no-one who approaches this question with an open mind will have any doubt, after reading his book, that the need for pasteurisation is fully justified by the evidence For marshalling this evidence the public weal is greatly in his debt

---

Major B W Rycroft, RAMC, has been appointed surgeon oculist to the King of the Hellenes and above the 1000 c cm needed to balance the normal daily output, and the amount needed to make up for vomiting or diarrhœa The adequacy of treatment must be controlled by daily weighings, for it is not possible always to measure the urinary output Dehydration must be relieved within a few hours, and in the infant with "d and v" the vomiting often ceases as soon as this has been done

YOUNG suggested that the fluid used to make up fluid loss should be "half-normal" saline (0 45% NaCl) containing 2½% glucose, and that subsequent fluid should be "one-fifth normal" saline (0 18% NaCl) containing 4% glucose , 300 c cm of the stronger solution should be given intravenously, accompanied by as much as is necessary of the weaker solution by the same route or by mouth Failing the skilled personnel to carry out the intravenous technique the solutions could be given by mouth YOUNG did not favour subcutaneous administration of fluid because it is only rarely that sufficient fluid can be got in by this route, and there is no control over the rate of absorption There seems to be no advantage in giving bicarbonate or lactate (Hartmann's solution) with the sodium chloride The infant body can select the proportions of sodium and chlorine it requires, provided that sufficient water is available for adequate renal excretion , this is borne out by adult experience, for neutral sodium chloride intravenously is equally effective in the alkalosis of pyloric stenosis and the acidosis of diabetic coma Among other speakers at the RSM meeting there was considerable support for subcutaneous saline, and it was suggested that saline by mouth was unpalatable to the infant and might lead to insufficient intake and in many cases vomiting But there was agreement that the relief of dehydration is an urgent matter, that "physiological" saline is not an appropriate fluid to use, and that it is necessary to work out precisely the minimum fluid requirements of the sick child, and to ensure that the proper amount is given, whatever route is selected It is not enough just to "set up a drip"

SCIATICA IN THE FORCES

IN the Services, where there is a special need for rapidity and accuracy in diagnosis and disposal, sciatica does not seem to be following clinical tradition Constant contact with the same patients—no longer free as civilians to seek another doctor—has disproved the legend that the disease is self-limiting and only occasionally recurrent , it shows a well-marked tendency to chronicity, giving rise to considerable wastage in hospitalisation and invaliding and offering an avenue for neurotic escapism Always demoralising in peace-time, it becomes doubly so under Service conditions , good men struggle to continue at their jobs but those of weaker fibre may end with an hysterical perpetuation of organic symptoms An Army bulletin[1] points out that sciatica no longer means a specific disease due to a true neuritis, but has come to indicate a syndrome of postcrural pain of many possible origins Early diagnosis and treatment are of cardinal importance , patients should be admitted to hospital for anything more than a minor attack, and thorough examination carried out This should include a careful record of the nature of the pain, its mode of production and relation to injury or occupation, of any changes in sensation, muscle-power or reflexes in the legs, and of the function of the lumbosacral spine Accessory investigations include radiograms of lumbar spine and pelvis, lumbar puncture, and (for soldiers are not immune from malignant pelvic disease) rectal examination Myelography with iodised oil or air should not be done except under a neurologist's advice Not least in importance is an assessment of emotional state and resistance to pain Among the common causes, fibrositis of the fasciæ, muscles, ligaments or joint-capsules in the lumbosacral, gluteal and hip regions is often associated with trauma, postural strain and congenital bony anomalies rather than focal sepsis The pain is referred from the more deeply situated lesions which may require location with an exploring needle, and KELLGREN[2] has found 70% of cases to originate in this way These respond to the familiar technique of local injection with procaine,[3] in which the criteria of an immediate aggravation of the pain followed by permanent or semi-permanent relief must be satisfied if the diagnosis is to be confirmed Where the lesion is inaccessible to the needle manipulation may succeed With sciatica of fibrositic origin there should be no disturbances of sensation or tendon-reflexes in the legs , these, if present, are symptomatic of a neuritis or radiculitis, or of a prolapsed intervertebral disc In the former, recently under fire as an entity but championed by this bulletin, an acute onset of often severe pain is associated with tenderness of the nerve and hamstrings, slight sensory impairment, occasional weakness in dorsiflexion of the foot and a diminished or absent ankle-jerk The cerebrospinal fluid, normal in a neuritis, may in radiculitis contain an excess of protein and lymphocytes A chronic neuritis may respond to the perineural injection of procaine, but the use of oxygen here or subcutaneously is not devoid of risk , radiculitis may be relieved by epidural injections of procaine followed by normal saline

With prolapsed intervertebral disc, which SYMONDS[4] regards as by far the commonest cause of sciatica in Service cases, trauma is of ætiological significance, but may be entirely absent and should not be regarded as essential in the history The common story is of back strain while stooping, followed fairly soon by low back pain, and, perhaps weeks later, by sciatic pain worse on exertion or coughing Scoliosis, tenderness of the nerve and of the hamstrings and calf-muscles, weakness of the plantar and dorsiflexors of the foot, and a diminished or absent ankle-jerk are common physical signs Sensory changes are usual in the form of hypæsthesia on the outer side of the leg below the knee and on one or other border of the foot, with loss of postural sensation in the corresponding toes Occasionally there is bilateral pain and sphincter disorder, but this cauda equina syndrome more usually follows the unwise manipulation of a case of disc prolapse, or, as a florid progress of symptoms and signs, is due to the rarer causes of gross spinal disease, pelvic tumours and tumours of the cauda itself Once the diagnosis of prolapsed disc is made—and this is largely on clinical grounds alone, for plain radiograms are unhelpful, air-myelography standardised McNEE and REID, using both a positive and a negative pressure method, could find no correlation between capillary fragility and degree of saturation Using the positive pressure method they also found no increased fragility in four out of five cases of frank scurvy The question of technique has been examined by BELL and his co-workers,[5] who found little correlation between a positive pressure method[6] and a negative pressure method[7] Moreover SCARBOROUGH[8] has adduced evidence that deficiency of vitamin P plays a part in making capillaries more fragile It is clear that assessments of nutritional level in vitamin C by means of tests for capillary fragility must be interpreted with caution

[3] Good, M G *Ibid* 1942 ii 597

[4] Symonds, C P *Proc R Soc Med* 1942 35, 511

The last type of evidence for the detection of a deficiency—clinical tests—would include the recognition of early signs of deficiency and of improvements in health after increasing the vitamin intake Early signs of vitamin-C deficiency are vague and certainly not pathognomonic Recording the effect of increasing the intake—the therapeutic test—requires intensive and well-controlled experimental observation Where reliable tests of this sort have been carried out, the evidence of mild malnutrition seems fairly conclusive—for example, the report from Germany[9] of the increased height and weight and improved health of school-children, and the paper of GLAZEBROOK and THOMSON[10] on the reduced incidence of pneumonia and rheumatic fever, both resulting from an addition of vitamin C to an ordinary diet, suggest that the symptomless deficiency indicated by studies of diet and by the saturation test is real

DEHYDRATION IN INFANTS

AN understanding of the differences in renal mechanism between adult and infant—differences which are exaggerated in the premature infant—is essential if infants suffering from dehydrating disease such as gastro-enteritis are to be given the best chance of recovery Present knowledge of this subject, and its application to therapy, was summarised at the therapeutics section of the Royal Society of Medicine on Nov 10 by W F YOUNG The normal newborn infant's body contains 80% by weight of water, against 72% in the adult, and in the infant a much larger proportion of that water is extracellular than in the adult For its weight the infant's fluid requirements are far greater than those of the adult, the daily requirement of a newborn infant being some 150 c cm per kg, against 50 c cm per kg for the adult With McCANCE[11] and HALLUM,[12] YOUNG has demonstrated that the glomerular filtration rate and urea clearance per sq m of body surface is much lower in infants, especially the premature, than in adults, in short-time experiments they were found to vary with the urinary output The electrolyte clearances, particularly of sodium and chlorine, were also much lower than in adult life GORDON, HARRISON and McNAMARA,[13] in New York, have confirmed these results, but using a 24-hour observation they noted less variation in the clearances as minute volume of urine secreted was varied presence of high columnar epithelium in the infant glomerular tuft, demonstrated by GRUENWALD POPPER[14] may explain these differences adult and infant

The practical significance of these findings is obvious Of the normal water intake at any age only about is available for renal excretion, the remainder being lost through the lungs, as insensible perspiration, and in the fæces Owing to its larger surface, although the infant's intake per unit of body-weight is much greater than the adult's, the amount of water lost by extrarenal routes is roughly the same; hence, if the extrarenal losses are increased by fever, hyperpnœa, vomiting or diarrhœa, the water available for the kidneys may readily be reduced to the danger point The adult kidney compensates for low urinary volume by greater concentration of solids in what water is available, the infant kidney is unable to do this in the same degree, so that as soon as the urinary output falls the normal chemical composition of the body fluids is no longer maintained The blood urea rises rapidly, to diminish again as quickly if dehydration is removed Similarly, since the infant kidney is *not efficient at concentrating* salts, it is easy, as ALDRIDGE[15] has shown, to produce œdema with high blood sodium and chlorine if saline injections are given to relieve dehydration So sensitive indeed is the infant to excess salt that œdema may be produced by change of diet from human milk to cow's milk, by reason of its greater salt content What is important in this recent work is the demonstration that the happenings in the infantile renal mechanism accompanying dehydration are not, as was previously thought, evidence of renal abnormality but are simply due to too little water available for excretion The explanation indicates *at once the main* lines of treatment Enough water must be given to replace what has been lost, and in addition enough to enable the kidneys to function efficiently, this means an intake greater than normal, to compensate increased extra renal losses The lost salt must also be replaced, with due regard to the risk of salt poisoning In the infant the gastro-intestinal secretions are either iso or hypo tonic, so the salt lost is certainly not more than the amount corresponding to the water lost. Administration of physiological saline may be safe and valuable in adults, although in them there is a certain risk of poisoning from *too much* salt, *in infants it is a dangerous drug* Remembering that at best only half the water taken is available for renal excretion, and that the infant kidney can rarely secrete urine containing more than 1·4% of salt, it is obvious that 0 85% saline may rapidly lead to serious salt poisoning Treatment cannot be regulated by biochemical findings, for at best the estimation of sodium and chlorine takes some hours It has been found, however, that mild dehydration means a loss of about 4% of the body fluid and severe dehydration one of about 8%, and these figures can be used as a basis for initiating therapy Taking an infant of 15 lb (7 kg) normal weight, and assuming a loss of 6%, some 300 c cm of fluid is required merely to relieve dehydration over nstitutional disturbance They are irreversible as e the very similar changes seen in severe vitamin-A ficiency, where normal mucosa does not reappear even en the deficiency is made good Yet nasal mucous embrane is known to possess considerable powers of generation to normality—for example, after erosion e to acute infection or deliberate operative removal his may be because squamous epithelium is usually e end-result of epithelial differentiation and once rmed shows no tendency to revert to another type, ssibly because the essential reason for the changes is ntinuously operating Thus, from what is known of the tural history of atrophic rhinitis in the last fifty years d the pathology, an obscure defect of metabolism is e most likely cause

A speculative belief of the ancients in a naso genital lationship, revived by Mackenzie,[4] has recently reived some scientific approval Mortimer, Collip and hers[5] observed that reddening and swelling (or swelling one) of the middle and inferior turbinals followed ypodermic injection of the œstrogenic hormone in the acacus The hormone made up in oil was then given tranasally to patients suffering from atrophic rhinitis, nd a clinical improvement was recorded The method as adopted by many other workers with more or less ccess and some publicity Hall and MacLeod[6] report n 23 cases treated by intranasal spraying with œstrin in l and conclude that relief is given to all patients some eing cured Objective recognition and measurement is ot easy but an attempt was made by Eagle Baker and amblen[7] who examined sections of nasal mucous membrane removed before and after the course of treatment They observed 22 cases but biopsy specimens ere taken from only 14 They found that although ubjective clinical improvement occurred in nearly all ases and the mucous membrane appeared smoother and ore hyperæmic and fewer crusts were present, yet no hanges could be demonstrated microscopically Thus he only objective test was negative A feature common o all these papers is the insistence on careful intranasal leansing before applying the oil, and this is deemed to be f such importance that it is occasionally performed by he surgeon himself That regular removal of crusts and nremitting intranasal hygiene gradually result in linical improvement must be remembered in considering the validity of any deductions Although crystalline progesterone is absorbed by the uterine lining membrane, there is no proof that œstrogenic substances are absorbed through normal nasal mucosa, much less through a mucous membrane largely composed of stratified squamous epithelium This proof, and a series controlled by cases treated with the same cleansing measures but no hormone, checked by biopsy examinations, would be helpful in deciding whether the therapeutic claims are justified

ANXIETY IN CHILDHOOD

THE psychiatrist, the pædiatrician and the educator, Dr B I Beverly remarks,[8] who went their several ways twenty years ago, now find themselves exploring the common ground of two basic principles. that anxiety in adults is largely a renewal of the anxiety of adolescence, which in turn is an expansion of anxieties in the first three years of life, and that the greatest hope for better health lies in prophylaxis Extreme anxiety states, once believed to be rare in children, are actually he thinks not uncommon, he has seen 10 cases in 2 years, and gives typical case-histories These, as he says, are monotonously alike, of the 9 cases quoted 7 were girls, except for one girl of 17 the whole group were aged over 10 years and under 13 They were of normal intelligence and they nearly all suffered from bouts of panic in which they would cry, fancy someone or something was coming after them, and complain of nausea or abdominal pain Often an alarming experience—such as death of a friend or a friend's mother—had preceded the first of the bouts of panic In nearly every case one or both parents resented the child, or one parent was unduly apprehensive and fussy Nearly all had been strictly managed in infancy by a parent who had determined that they should achieve some impossible criterion of polite behaviour, and the parents had won, for they were all too good and well behaved to be normal Because they could feel no security in their parents, they resented this treatment secretly, hate of the oppressive parent filled them with feelings of guilt, and fear of their own guilty hate found expression in somatic symptoms through stimulation of the sympathetic nervous system Dr Beverly's treatment consisted in gaining their confidence until they could speak of their resentment and then getting them to realise that other people felt the same towards their parents, and that they were not going to be punished for it This line was usually successful, as success in psychotherapy goes, thus he says of one patient "She began to fight more with her brother and talked back to her parents the way a normal child should" But he believes that these patients will never entirely recover The harm done by insecurity during infancy cannot be cured they will always be easily frightened While extreme reactions are unusual, milder forms of the condition, provoked by similar environmental factors are seen every day They could be prevented The last case he quotes is that of a child of 4 months whose mother believes children should not be spoiled, she also does not like babies and does not "feel right" about her own, at the same time, to smother her own guilt, she exaggerates the importance of all trivial matters to do with the baby Cases of the kind, he feels with justice, place a great responsibility on the pædiatrician; if he fails presumably the responsiblity, like the baby, is handed on in turn to the educator and the psychiatrist

WORKSHOPS FOR THE TUBERCULOUS

THE danger of giving people protected jobs, so Dr Herman Biggs held some years ago, is that you may turn a sick self-respecting workman into a healthy loafer Mr Edward Hochhauser, president of the Altro Workshops, a voluntary enterprise for the rehabilitation of tuberculous patients in New York, feels sure, however, that the sheltered workshop has a part—though a limited one—to play in aftercare[1] These workshops are a unique experiment in that they not only tide a man over the gap between his discharge from sanatorium and his return to industry, but prepare him during that time to work successfully in a competitive world A study made by the workshops five years ago shows that though most employers will take back one of their own men who has developed tuberculosis, only about 40% are willing to employ a new applicant who has it Many of those who took tuberculous workers back made special conditions of work for them, thus one company employing 19,000 workers provided a complete medical service for them, and insisted that their 200 tuberculous employees should only work part-time until recovery was achieved Another company was able to provide such favourable conditions for tuberculous workers that their average attendance record was better than that for the whole group of employees Mr Hochhauser finds that the possibility of a job with his old employer is good therapy for a patient in a sanatorium and—provided his job depends on recovery—ensures adequate stay, disability pensions which have no reference to rehabilitation or employment put a premium on invalidism and are unsound unreliable and the iodised oil now available too irritant—the Army patient should as a rule be invalided even if he recovers, recurrence is frequent, and operation should be reserved for key-men who can be kept on in sedentary employment From experience in the RAF, **Symonds** agrees that diagnosis should be made without the use of contrast media, and, though he advises a trial of long immobilisation, he has found operation so unsuccessful in getting men back go duty that he would invalid the patient if immobilisation fails

Whatever the cause of the pain, symptomatic treatment in the first attack will consist of rest in bed and analgesics, with local heat Complete rest from the outset until the pain has gone should replace perseverance with ambulatory treatment, which may encourage chronicity In all cases, attention to morale is of the greatest importance, diversional therapy during the early confinement to bed and more constructive work later will help to prevent the psychoneurotic accentuation and perpetuation of symptoms Ways of achieving this end have been suggested by **Jefferson**,[5] and success in avoiding these complications may seem some compensation for the not infrequent failure of physical therapeutics

CLINICS FOR WOMEN'S AILMENTS

Treatment of venereal diseases in the Forces is intensive and efficient, but the British Social Hygiene Council believe that facilities are not adequate for treatment of civilians, especially women, seafarers and industrial workers in rural areas Their plea to local authorities, first published in 1940, asked for an educational campaign among women on the lines that neglect of any female ailment—any discharge or pain, for example—might have serious consequences, and perhaps interfere with a healthy family life As a complement to such teaching, they consider that clinics for treatment of ailments of women should be set up, offering free diagnosis and, when necessary, treatment Such clinics would be staffed by doctors experienced in both gynæcology and venereal disease, and since they would treat both types of case no stigma would attach to patients attending The gynæcological work of the clinic could be financed under the maternity and child welfare provisions made by the Ministry of Health. The Government has undertaken to contribute 75% of the cost of any extra treatment facilities made necessary by war conditions, unfortunately there is at present a ruling that ailments of women clinics and VD almoners cannot rank for the 75% grant The council contend that this ruling should be reversed, and indeed suggest that the cost of new facilities made necessary by an influx of new population into an area should be borne entirely by the Government, local authorities not being asked to meet new charges in what is really a national emergency

The present position, as set out by the council in a note to Members of Parliament entitled *33B and the V D Situation* (from Tavistock House, W C 1) is that 70,000 new cases of venereal disease were reported from civilian clinics last year, and that the figures of incidence have risen to the level reported in 1932 Men at the peak age of infection (19–23) in the Forces are effectively treated, but there are no special provisions for treating men of the Merchant Navy as there are for the fighting services, and in many of the small ports now being more used facilities for treatment are inadequate Wives and partners of men in the Services or Merchant Navy are scattered in war industries throughout the country, would probably seek confidential treatment volun if it were available conveniently and without social st Were civil clinics meeting the needs of women they wo now be treating more women than men, but the rev is the case Transport difficulties and industrial dispe deter infected people from attending, moreover clinic hours often coincide with working time, and wome especially will not ask for time off to attend because o the necessity of explaining to employers Most clinic have no follow-up service, and in many places loca administration nullifies the regulations for repayment o fares to patients Almoners have been extremel successful in persuading contacts to accept voluntar treatment, and if ailments of women clinics are set up th council consider that men and women should b appointed to the medical officer's staff to advise and hel patients and seek out contacts

Defence Regulation 33B, which makes it possible t compel people to come for treatment if they are name as the source of infection by two patients,[1] is now unde discussion in the House on a prayer to the Governmen for its revocation The council would like to see i replaced by a new regulation giving similar powers o compulsion, but ensuring also that proper facilities fo voluntary treatment would be provided These woul include not only clinics organised and staffed as suggested, but opportunities for short intensive course of treatment in hospital, and arrangement of clinic hour to suit the convenience of patients in jobs The suggest, too, that as a war measure the Wasserman reaction of all pregnant women should be done

ATROPHIC RHINITIS AND THE ŒSTROGENIC HORMONE

Within the memory of older practitioners certai diseases have almost disappeared and others have becom rarer The anæmia of female adolescence—chlorosis—is a striking example of the former, and atrophic rhiniti of the latter These two diseases have several othe common features both mainly affect females, patient first come under observation in adolescence, and the bul of them are from the poorer classes, improved hygien and sanitation, changes in diet and more outdoor exercis are all believed to play some part in their gradual disappearance There is no precise knowledge of the ætiology of atrophic rhinitis, but even strong advocate of other theories, Cullom,[2] for instance, admit tha nutrition is an important factor, and a study of th pathology lends additional support to this view Th morbid anatomy of atrophic rhinitis has been classicall described by Wyatt Wingrave[3] As its name indicates the changes are those of atrophy or degeneration Th subepithelial tissues become broken up by increase in fibrosis The mucous glands atrophy, possibly because of a resulting impairment of their nutrition, and hyalinisation and pigmentation follow The epithelial basement membrane breaks up and disappears, and the epithelium itself changes from a ciliated pseudostratified columnar to a stratified squamous type In other words, the pattern of the whole mucous membrane alters from one of activity to that of inactivity The function of the respiratory mucous membrane is to secrete mucus, which it then moves into the nasopharynx as an unbroken sheet by means of its cilia The mucus warms inspired air and also traps and acts upon foreign matter The changes described are followed by a scantier secretion of more watery mucus and a discontinuity of the mucus sheet in areas where the cilia have disappeared These stationary masses of mucus dry and form the crusts characteristic of the disease It is remarkable that such drastic local changes are not accompanied by any apparent

GENERAL MEDICAL COUNCIL

WINTER SESSION NOV 24–28, 1942

AT the conclusion of the President's address, reported in our issue of Nov 28 (p 653), the council ratified the appointment of Prof J A Nixon, Mr H Collinson and Sir William Fletcher Shaw to inspect the qualifying examinations to which students are being admitted earlier as an emergency measure

Under the temporary provision order Dr E A Gregg was appointed to the vacancy on the council, left by the death of Sir Henry Brackenbury, as direct representative for England

Charges against Medical Practitioners

The council then considered five postponed charges of drunkenness and one of indecent assault, and made no erasure They erased the name of *Christopher Bastible,* MD NUI, against whom a further conviction had been recorded in August, 1942 of being drunk and incapable and failing to surrender to bail

A CERTIFICATE OF EPILEPSY

The case of *Ali Ahmed Hoda*, registered as of c/o Barclays Bank, Forest Road Branch Walthamstow London, E 17, MB Bombay (1920), who had been summoned to appear before the council on the following charges

In the Case of C D That being a registered medical practitioner

1 You gave the following certificate in your professional capacity for subsequent use for administrative purposes under the National Service (Armed Forces) Act, 1939 —

266, Forest Road, Walthamstow, E 17, 23/5/40

This is to certify that Mr C D of is in my opinion suffering from Epilepsy He has been under my care for the same for the last about 10 years Although I have not seen him in actual fit, I have on several occasions attended him after these attacks and once for injuries resulting by falling on the face during a fit about 2 years ago He was examined by Dr L R Yealland, MD, FRCP, of 136, Harley St, whose Diagnosis of the case is the same as mine

A Hoda, MB

C D

Witness to the above signature A Hoda, MB

2 You stated in the said certificate given by you on May 23, 1940 that the said C D was in your opinion suffering from epilepsy, and that he had been under your care for the said condition for a period of ten years before that date whereas in fact he had not been under your care for the said condition or alleged condition for any such period or at all

3 You did not make any or any proper professional inquiries before you gave the said certificate

4 The certificate given by you in the case of the said C D was untrue misleading or improper within the meaning of paragraph 1 of the Warning Notice issued by the General Medical Council dated June 1933

5 You gave the said certificate for the purpose of enabling the said C D who was to your knowledge a person who might become liable under the National Service (Armed Forces) Act, 1939 to be called up for service, to evade any liabilities which he might become liable to discharge under or by virtue of the Act

6 You conspired with the said C D and with other persons for the purpose of enabling the said C D to evade his liabilities under the National Service (Armed Forces) Act 1939

7 You aided, abetted, counselled or procured the said C D to produce in himself an apparent disability, and thereby to affect his apparent suitability for service in the Armed Forces of the Crown, by instructing him, or causing him to be instructed in or about April, 1940, how to simulate the symptoms of epilepsy for the purposes of an examination by a registered medical practitioner engaged in special practice to whom you had referred him

And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect

In the Case of I J That being a registered medical practitioner

1 You gave the following certificate in your professional capacity for subsequent use for administrative purposes under the National Service (Armed Forces) Act, 1939 —

266, Forest Road, Walthamstow, E 17, 15/6/40

The Chairman, Army Medical Board

Dear Sir,—Mr I J of is suffering from Grande Mal He has been under my care for some considerable time He is at present receiving treatment as directed by Dr Browning Alexander of 42, Harley Street, W 1

Yours faithfully

A Hoda, MB

2 You stated in the said certificate given by you on June 15, 1940 that the said I J was suffering from Grande Mal and that he had been under your care for some considerable time, and thereby implied that you had attended or treated him for the said time for the said condition, whereas in fact you had not attended or treated him for any such condition or alleged condition for any such time or at all before February or March, 1940 when you had only seen him on one occasion with reference to the said condition or alleged condition

3 You did not make any or any proper professional inquiries before you gave the said certificate

4 The certificate given by you in the case of the said I J was untrue misleading or improper within the meaning of paragraph 1 of the Warning Notice issued by the General Medical Council dated June 1933

5 You gave the said certificate for the purpose of enabling the said I J, who was to your knowledge a person who might become liable, under the National Service (Armed Forces) Act, 1939, to be called up for service, to evade any liabilities which he might become liable to discharge under or by virtue of the Act

6 You conspired with the said I J and with other persons for the purpose of enabling the said I J to evade his liabilities under the National Service (Armed Forces) Act, 1939

And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect

The complainants were the Ministry of Labour and National Service, represented by Mr Gerald Howard counsel, instructed by the council's solicitors, Messrs Waterhouse & Co Respondent was represented by Mr P Sandlands, KC, and Mr T F Davis, instructed by Messrs Bulcraig & Davis (Three other similar charges were printed, but no evidence was offered in support of them)

C D testified that he had suffered from fainting fits, but he had never heard them called epilepsy, Dr Hoda had not used the word to him He did not know what was in the certificate which he had handed to the medical board He had been put in grade 4 Later on, he had been seen by another medical board which put him in grade 2 He had been a patient of Dr Hoda for some ten years He did not know what his fainting fits were due to, they were few and far between He had told Dr Yealland the truth about them, and Dr Yealland had examined him at length He admitted signing his name on the medical certificate given him by Dr Hoda, but maintained that he had not read what was on it

G H, in respect of whom similar charges had been proffered, said that he had seen Dr Hoda in 1938. He had never had fits, but had lapses of memory and varicose veins He had asked for a certificate Nothing had been said about epilepsy.

(Mr Howard, after hearing this evidence, withdrew the charge in this case)

I J, an officer, said he had had fits nine or ten years ago, but no recurrence of that type He had fainted since then from time to time He had wanted to avoid military service and had rather exaggerated his symptoms He had paid money to a man called Lipschitz through a third party and Lipschitz had accompanied him to Dr Hoda, Lipschitz had coached him in his answers to the doctor He was put in grade 4 by his medical board in June, 1940 After questioning by the police he voluntarily submitted himself to another examination

Dr Hoda gave evidence on his own behalf, and maintained that he had told C D that he had epilepsy when he became of an age to be told, and that he had treated him with bromides and phenobarbitone He had said he would like a second opinion when C D asked for a certificate, and the consultant had confirmed his diagnosis C D's parents had frequently described the fits to him, and how C D had cut his head when unconscious He did not keep records of cash payments

Mr Sandlands pointed out that his client was charged with two statutory crimes, trumped up under the phrase "infamous conduct"; and emphasised the difference between the council's procedure and that of the criminal courts He argued that the council was not a suitable tribunal to judge crime The only evidence against his client was that of an accomplice He put in testimonials and asked why the police had not prosecuted when they made inquiries in July, 1940.

The council did not find the charges proved

TWO ERASURES FOR IMPROPER CERTIFICATION

The case of *Louis Aimee Newton* registered as of the Elms, Stanley Road, Teddington, MRCS (1928) who had been summoned to appear before the council on the following charges

In the Case of A B That being a registered medical practitioner

1 You gave the following certificate in your professional capacity for subsequent use for administrative purposes under the National Service (Armed Forces) Act 1939 —

The Elms, Stanley Road, Teddington, 23/3/40

This is to certify that I have attended A B of for the past six months during which time he has had attacks of fainting which are epileptic in character He loses consciousness and does not remember anything about them He has been on luminal gr 1 tre die for the past five months

L A Newton, MRCS

2 You stated in the said certificate given by you on March 23, 1940 that you had attended the said A B for a period of six months before that date, whereas in fact you had not attended him for any such period, or at all before March, 1940

3 You did not make any or any proper professional inquiries before you gave the said certificate

At present in America there is a good chance of getting the tuberculous worker employed after treatment, but there, as here, the gap between leaving the sanatorium and entering full work is a period of dangerous privation for many Those with limited or uncertain work tolerance, and those with advanced disease of doubtful prognosis need, he believes, a hardening centre or a sheltered workshop or colony The sheltered workshop should undertake the medical, social, psychiatric and economic care of the patient and his family, it is not enough to provide part-time work with rest facilities if the patient then goes to an insanitary and overcrowded home with insufficient income The workshop aims at his physical, psychological and social readjustment and at preventing relapses Materials made in the workshop are sold competitively and patients are paid at prevailing union rates for work done This is possible because over a period of years the Altro Workshops have built up a monopoly for some types of goods Thus they manufacture hospital uniforms with the trade name of 'Sterigarm,' and have cornered the market for this merchandise Relative monopolies of the kind form the basis of all successful rehabilitation centres which aim at paying a full wage Over here Papworth is famous for its trunks and portable buildings, and Preston Hall for portable buildings and printing

In New York state a patient must present a doctor's report that he is fit for 7–8 hours work daily before he can take a trade training At the State Rehabilitation Bureau an experiment has been begun under which suitable sanatorium patients can start vocational training if they have a 4–6 hour work tolerance and if the prognosis for full-time work falls within the time necessary to complete the course, and there are hopes that this plan will become accepted policy. As it is, patients have to be kept for 2–4 months longer than need be in sanatorium or sheltered workshops before they train for a trade, or else their trade training must be paid for out of private funds, which means that only a limited number of them get trained The sheltered workshops, Mr Hochhauser believes, should serve primarily those who need a modified environment for from 6 months to 3 years, but should also have room for a small group needing permanent sheltered employment The Altro Workshop has run for 27 years, at first only early cases were accepted, but of late years about 90% are moderately advanced cases and 10% are patients needing permanent care Results have been good with cases that become stabilised, and satisfactory with the unstable group, many of whom have been graded up to a full day's work and have continued to work for 10–25 years afterwards, and some admitted as permanent sheltered workers have later passed out into industry In 1915 there was room in the workshop for 22 patients, nowadays it takes 156 with 10 ex-patients The present premises, built in 1925, were planned so that another floor can be added and the capacity increased by 60 or more Not all patients discharged from sanatorium need a sheltered workshop, and graduated work in industry under intelligent supervision has advantages which, as he pointed out, a philanthropic enterprise lacks But for some patients the workshop provides just the bridge between sanatorium treatment and full work which they need

THE MAKING OF PHYSICISTS

ABSTRACT though it is, physics is more closely bound up with practical life and with industry than most of its fellow sciences The symbiosis could be even more productive if we made a few adjustments in our methods of training and distributing physicists, as Sir Lawrence Bragg has pointed out[1] He thinks we are not bad, on the whole, at producing the men for the job Our students are not equipped with the knowledge, mathematical ability, power of philosophic generalisation industry possessed by, say, the German student of the type, but they have a compensating horse sense w enables them to hold their own, and we rear about of them per million population every year They almost entirely from the grammar and secondary sch Our system of a continuous course through sch and university gives boys, he thinks, too unbro a concentration on the acquisition of knowledge a not enough practice in using their hands He examined honours students who could write a g answer on the structure of the atom but could not sold two wires together, and he finds American studen thanks to the experience of manual work which th commonly acquire in their long vacation, "more practic handy and bold at setting up apparatus" He suggests that English honours students should work for months in a laboratory of some industrial concern at apprentice's wage between leaving school and ente the university, so that they start the course with at least the knowledge of a lab boy Then we make the student's career depend too much on answering examinatio questions rather than on "grasp of principles, initiative, cleverness of manipulation and vitality" These qualities could be encouraged, Bragg suggests, by inviti industrial technical workers to give special courses in the universities, such experts would then have a chance to add their counsel when policy is discussed

Physical research, Bragg believes, is on the whole better conducted in a university than in an institution set aside for research and nothing else The constant flow of young men, bringing fresh minds and original ideas to bear on the work in progress, and the intercourse with men doing widely different work, as well as the demands of teaching, help to keep the university physicist from the dangers of stasis Purely research institutions should be regarded not as a body of men but as a body of equipment to which firms could send men to develop some good idea over a year or more A body of men working at research alone along some suggested line lack both the incentive of free chase after any fascinating scent which keeps the university researcher on his toes, and the calls of his industry which move the industrial physicist They are working in a vacuum and they get stale No one can say "I will have a good idea this morning" Ideas choose their own moment, but they can be stifled by administration and routine An organisation which spends the nation's money on research is apt to require the worker to account for every moment of his time and to indent for every new piece of apparatus But a man with a new idea should start work instantly while it is still red hot; he needs plenty of old junk at hand to make his rough models, and the liberty to buy other odd bits of equipment as he needs them In the long run it is more economical to give him this freedom By all means let him do things "through the proper channels" —but let the channels be direct and open

Jewish National Library—It is now fifty years since the Jewish national library was established in the Jewish University at Jerusalem Professor Weil, director of the library, in his broadcast on the occasion of the jubilee, said that one of the most enthusiastic contributors to it had been the Russian physician Chazanowitz, for many years he collected volumes for the library, for which the present building on Mount Scopus was afterwards erected In 1900 there were 15,000 volumes in it, now there are 440,000 Every resident in Palestine can use it, and during 1941 64,000 readers were enrolled For the benefit of doctors six medical branches are maintained in different parts of Palestine, this medical section has been built up by the committee of American-Jewish physicians The library-staff hope to ensure in the future that every important publication in the world on Jews and Judaism shall find its way to Mount Scopus

The council did not find the charges proved

TWO ERASURES FOR IMPROPER CERTIFICATION

The case of *Louis Aimee Newton* registered as of the Elms, Stanley Road, Teddington, MRCS (1928), who had been summoned to appear before the council on the following charges

In the Case of A B That being a registered medical practitioner

1 You gave the following certificate in your professional capacity for subsequent use for administrative purposes under the National Service (Armed Forces) Act, 1939 —

The Elms, Stanley Road, Teddington, 23/3/40

This is to certify that I have attended A B of for the past six months during which time he has had attacks of fainting which are epileptic in character He loses consciousness and does not remember anything about them He has been on luminal gr 1 tre die for the past five months

L A Newton, MRCS

2 You stated in the said certificate given by you on March 23, 1940 that you had attended the said A B for a period of six months before that date, whereas in fact you had not attended him for any such period or at all before March, 1940

3 You did not make any or any proper professional inquiries before you gave the said certificate

4 The certificate given by you in the case of the said A B was untrue, misleading, or improper within the meaning of paragraph 1 of the Warning Notice issued by the General Medical Council dated June, 1933
5 You gave the said certificate for the purpose of enabling the said A B , who was to your knowledge a person who might become liable, under the National Service (Armed Forces) Act, 1939, to be called up for service, to evade any liabilities which he might become liable to discharge under or by virtue of the Act
6 You aided, abetted, counselled, or procured the said A B to produce in himself an apparent disability, and thereby to affect his apparent suitability for service in the Armed Forces of the Crown
7 You conspired with the said A B and with one S Pell and with other persons to enable the said A B to evade his liabilities under the National Service (Armed Forces) Act, 1939
And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect

In the Case of E F That being a registered medical practitioner
1 You gave the following certificate in your professional capacity for subsequent use for administrative purposes under the National Service (Armed Forces) Act, 1939

The Elms, Stanley Road, Teddington, 2/4/40

This is to certify that I have known Mr E F for some months He came complaining of weakness and tingling in his legs and also bad vision I find that he is almost totally blind in one eye and that he gets tremors on movement and that he has exaggerated reflexes I believe he has disseminated sclerosis

L A Newton, MRCS

2 You stated in the said certificate given by you on April 2, 1940, that you had known the said E F for a period of some months before that date, whereas in fact you had not known him for any such period but had seen him for the first time on April 2, 1940
3 You did not make any or any proper professional inquiries before you gave the said certificate
4 The certificate given by you in the case of the said E F was untrue, misleading, or improper within the meaning of paragraph 1 of the Warning Notice issued by the General Medical Council dated June, 1933
5 You gave the said certificates for the purpose of enabling the said E F., who was to your knowledge a person who might become liable under the National Service (Armed Forces) Act, 1939, to be called up for service, to evade any liabilities which he might become liable to discharge under or by virtue of the Act
6 You aided, abetted, counselled, or procured the said E F to produce in himself an apparent disability, and thereby to affect his apparent suitability for service in the Armed Forces of the Crown
7 You conspired with the said E F and with one S Pell and with other persons to enable the said E F to evade his liabilities under the National Service (Armed Forces) Act, 1939
And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect

In the Case of I. J —That being a registered medical practitioner
1 You gave the following certificate in your professional capacity for subsequent use for administrative purposes under the National Service (Armed Forces) Act, 1939

The Elms, Stanley Road, Teddington, 5/4/40

This is to state that I have known I J for the past seven years during which time he has suffered from epileptiform attacks He momentarily loses consciousness and falls down He is forgetful and slow in manner, but as he has been on bromides and luminal for some time, these may account for it L A Newton

2 You stated in the said certificate given by you on April 5, 1940, that you had known the said I J for a period of seven years before that date, and that during the said period he had suffered from epileptiform attacks, and thereby implied that you had attended or treated him for the said period for the said attacks; whereas in fact you had not attended or treated him for any such attacks or alleged attacks for any such period, or at all before March or April, 1940
3 You did not make any or any proper professional inquiries before you gave the said certificate
4. The certificate given by you in the case of the said I J was untrue, misleading, or improper within the meaning of paragraph 1 of the Warning Notice issued by the General Medical Council dated June, 1933
5 You gave the said certificate for the purpose of enabling the said I J who was to your knowledge a person who might become liable, under the National Service (Armed Forces) Act, 1939, to be called up for service, to evade any liabilities which he might become liable to discharge under or by virtue of the Act.
And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect

The complainants were the Ministry of Labour and National Service, represented by Mr Gerald Howard, counsel, instructed by Messrs Waterhouse & Co , solicitors Respondent was represented by Mr G D Roberts, KC, and Mr T K Edie

Charges in respect of C D and G H were withdrawn A B , E F and I J gave evidence, stating that they had been coached by a Miss Bentley in the way to simulate fits and answer questions Witnesses had paid sums of £200 or £250 to Miss Bentley or Mr Pell

I J had simulated a fit in front of Dr Newton His father was respondent's butcher and he had known him for seven years Dr Newton had treated him for hernia and minor lacerations He had had no difficulty in deceiving the Army medical board Miss Bentley had also taken him to another doctor, who had given him a certificate similar to Dr Newton's Miss Bentley had done most of the talking , he had pretended to be slow and drowsy and had shown scars produced by biting his tongue Miss Bentley had also taken him to a third doctor, who had given a similar certificate, stating that he patient in a fit This was not true , he had not front of this doctor He had begun to pretend he epileptic three or four months before his medical and had seen Dr Newton about once a week period, and had finally simulated a fit in order to him The Army medical board had been deceived had put him in grade 4 After the police had changed his mind and had volunteered for the The second medical board had put him in grade 2

Dr Newton, in reply to Mr Roberts, described his busy and successful practice, and said that he had A B at his surgery only He had complained of fits and had been given luminal tablets from the pensary

In reply to the President, he said he had r in Hackney, but his home was there He kept medical records , he had no time He did not think had asked A B if he was under any other doctor he came to the surgery A B had been brought to by Mr Pell, whom he had met socially at the C Hotel Mr Pell had said that a number of his clients near the doctor, and he would introduce them Dr N did not know where Mr Pell lived, but understood was an insurance agent with an office in the City had also introduced E F , who had complained nervousness, tickling in the legs and Respondent had sent him to a consultant, who agreed with the diagnosis of disseminated sclerosis certificate was quite true , and the medical board recorded the same finding He had never had money save 5*s* and 7*s* professional fees from people He had known I J for many years as the of his kosher butcher In the early days of the I J had begun suggesting epilepsy and had said he had not liked to disclose it earlier Witness had taken much notice until one day he had seen the boy a fit He had been completely deceived , the boy seem unconscious, his arm, leg and face twitched, his eyes we fixed and his trousers wet He had never heard of Mi Bentley, and knew nothing of the other two docto I J had seen It was quite untrue that A B 's fath had called on him and been very angry ; he had nev seen this man

Mr Roberts and Mr Howard addressed the counci which deliberated in camera, after which the Preside announced that they had found proved charges 1–5 and (except for the words "and with other persons ") in th case of A B and E F , and the charges 1–5 in respe of I J and that Dr Newton had been adjudged guilt of infamous conduct and his name erased from th Register

* * *

The case of *Arthur Carr*, registered as of 88, Brick Lan London, E 1, MRCS (1927), who had been summoned t appear before the council on the following charge

That being a registered medical practitioner
1 You gave the following certificates in your professional capacit for subsequent use for administrative purposes under the Nation Service (Armed Forces) Act, 1939

In the Case of C D

88, Brick Lane, E 1, 18/10/39

C D of has suffered from epilepsy since childhood His fit now occur at intervals of one to three weeks and are of a sever nature He is very backward mentally, and, in my opinion, i unfit for any kind of work His mother and two brothers are al epileptics Arthur Carr, MRCS, LRCI

In the Case of E F

88, Brick Lane, E 1, 29/10/39

E F of has suffered from epileptic attacks since childhood He is also suffering from mental deficiency He is now under the case of Dr G Konstam of 40, Harley St , W 1
He is unfit for any kind of work Arthur Carr, MRCS, LRCP

In the Case of G H

88, Brick Lane, E 1, 29/10/39

G H of has suffered from epilepsy since childhood His attacks come on at intervals of one to three weeks He is partially deaf owing to an old mastoid operation and he is mentally deficient He is unfit for any work He is now under the care of Dr J Burnford of 4, Devonshire Place, W 1, for his epilepsy
Arthur Carr, MRCS, LRCP

88, Brick Lane, E 1, 30/10/39

G H of is an old epileptic with frequent attacks since child hood He is also partially deaf owing to old mastoid trouble He is under the care of the West End Hospital for Nervous Diseases and has also been examined by Dr J Burnford of 4, Devonshire Place He is useless for any kind of work Arthur Carr MRCS LRCI

In the Case of I J

88, Brick Lane, E 1, 30/10/39

This is to certify that I J residing at is suffering from epilepsy and is unable to follow his occupation on 31/10/39 following epileptic attack

A Carr

88, Brick Lane, E 1, 6/11/39

I J of is suffering from idiopathic epilepsy The attacks began about six or seven years ago with minor manifestations, major fits occurring for the past four months During these attacks he bites his tongue and is incontinent of urine He is under the care of Dr Geoffrey Konstam of 50, Harley Street W 1 He agrees that he is suffering from epilepsy but in view of his rather slow reaction-time he is having him admitted into hospital for observation and investigation as there is a possibility of a cerebral tumour being present

Arthur Carr, MRCS, LRCP

88, Brick Lane, E 1, 14/11/39

Mr I J of is suffering from epilepsy He is under the care of Dr Geoffrey Konstam of 40, Harley St , W 1 He was admitted into the East Ham Memorial Hospital last week for investigation as there was the question of a cerebral tumour being present He has had his head X rayed, and his CSF and WR done Since the lumbar puncture he has had very severe headache

I have not yet been informed of the results of the investigations

Arthur Carr, MRCS, LRCP

88, Brick Lane, E 1, 20/12/39

I J of has been having attacks of dizziness for six or seven years These passed off quickly and recurred about every month About six months ago major attacks commenced during which there would be an aura of headache, and after a few minutes he would throw himself about, bite his tongue and lose consciousness He usually was incontinent of urine during the attacks The history suggested a typical history of epilepsy He was sent to see Dr Geoffrey Konstam of 40, Harley Street who agreed with this view but who thought that his reaction time was slow and should be further investigated He was therefore admitted into East Ham Memorial Hospital and had his CSF, WR, &c , done No signs of cerebral tumour were found and after a week was discharged as being suffering from idiopathic epilepsy At this time he suffered from intense headache—? due to lumbar puncture During the past six weeks he has had about five fits but are now becoming somewhat less frequent He is on tab sod phenobarb gr 1 bds He finds the tablets have a soporific effect There are still spells of dizziness

Arthur Carr, MRCS, LRCP

In the Case of K L

88, Brick Lane, E 1, 18/3/40

K L of has been suffering from epileptiform convulsions for the past five years During these attacks which occur every few months, he usually bites his tongue and wets himself They frequently occur during the night He had treatment intermittently but this failed to control his attacks Dr Bellingham Smith of 12, Wimpole St W 1, thinks the prognosis in his case is poor on account of the marked mental deterioration His view is that he may have to enter an institution sooner or later He is on luminal gr 1 bds There is an interesting atrophy of the right supra- and infraspinatus muscles

Arthur Carr, MRCS, LRCP

In the Case of M N

88, Brick Lane, E 1, 18/3/40

This is to certify that M N residing at is suffering from influenza and is unable to follow his occupation

Arthur Carr

88, Brick Lane, E 1, 28/3/40

This is to certify that M N residing at is suffering from post influenzal debility and is unable to follow his occupation

Arthur Carr, MRCS, LRCP

88, Brick Lane, E 1, 22/4/40

M N of has been suffering from epilepsy for some years He gets attacks of both grand and petit mal The mental condition is very poor, and Dr Pearse Williams of 144, Harley Street, W 1, under whose care he is is afraid that it will gradually develop into a state of chronic dementia He has suggested an institution for him but the relatives are very anxious to avoid this step He is at the moment having luminal gr 1 twice a day

Arthur Carr, MRCS, LRCP

In the Case of Q R

88, Brick Lane, E 1, 11/4/40

Q R. has been suffering from epilepsy for the past nine years He is a mental defective and has had very little treatment in the past for his condition He is under the care of Dr Hinds Howell of 145, Harley Street, W 1, who regards the prognosis as extremely bad He thinks that he might have to go into an institution under the MD acts He is on luminal gr 1 bds

Arthur Carr, MRCS, LRCP

In the Case of U V

88, Brick Lane E 1, 31/5/40

U V of has suffered from idiopathic epilepsy for many years His attacks occur frequently—every week or two He is under the care of Dr J Purdon Martin of 9 Harley St., W 1, who does not think that his mental condition is likely to improve At present he is having tab sod phenobarb gr 1 bds

Arthur Carr, MRCS, LRCP

In respect of each case the further charges were, mutatis mutandis, those printed as Nos 3, 4 and 5 in the case of I J under the Newton case No evidence was offered to support similar charges in cases A B , O P and S T The complainants, the Ministry of Labour and National Service, were represented by Mr Gerald Howard, counsel, instructed by Messrs Waterhouse & Co Respondent was represented by Mr A A Pereira, counsel, instructed by Messrs Le Brasseur & Oakley, on behalf of the London and Counties Medical Protection Society

Mr Howard explained that the eight cases in the charge fell into two groups the first (C D , E F , G H. and I J) had occurred in the last two months of 1939 and the second (K L , M N , Q R and U V) were in the period March 18 to May 31, 1940 The first three had been put into touch with Dr Carr by a Miss Brown , I J by a man unknown; and K L , M N , Q R and U V by Pomeroy, a man who held a position in the "National Eye Service," an institution close to Dr Carr's premises C D had paid £200, E F £350, G H 350 guineas and I J 50 guineas to Miss Brown Pomeroy had had £130 from K L , £150 from M N , £150 from Q R and £150 from U V In each case the person had shammed epilepsy before respondent They constituted such a systematic series that no doctor could have been deceived by all of them They came from districts as remote as Regent's Park, Brondesbury, Stepney and Finchley to see Dr Carr for the first time in Brick Lane None of them had ever suffered from fits of any kind

C D gave evidence that he had wanted to evade military service, and that Miss Brown had taken him to Dr Carr, instructing him how to behave and answering most of the questions Dr Carr had not asked him for previous history or treatments , he had acted too "foolish " for such questions to be reasonable Miss Brown had also taken him to Dr Konstam, where he had acted in the same way Miss Brown had accompanied him to the medical board and handed in certificates which he had never seen He was exempted, but at another board two months later he had been passed A1 ; grade 2 for eyes He had always driven a car

E F testified that Miss Brown took him to Dr Carr, having coached him for weeks in advance He did not behave normally, but pretended to be slow and stupid Dr Carr suggested a specialist, and gave Miss Brown a letter to take to the specialist Miss Brown had taken him to the consultant and he had behaved in the same way He did not simulate fits before the doctors He was brother to C D whom Dr Carr had seen in a similar condition Miss Brown had also accompanied him to a house near Dr X's home where an attack had been staged and Dr X called in He was now a motor driver in the Army He had seen Dr Carr twice, the specialist once and Dr X half a dozen times He lived at Brondesbury and went to see Dr Carr in the East End He had never seen a doctor in his life before. Dr Carr had received a letter from the specialist before writing his certificate

G H , brother of E F , testified that his father had introduced Miss Brown, who had taken him to see Dr Carr—to the East End from his home in the north west An old lady—Miss Brown's mother—had accompanied them, and had seen Dr. Carr first, pretending to be his grandmother Miss Brown was pretending to be his "aunt " She had told him to act stupidly, which he did. He had paid 350 guineas to Miss Brown in £1 notes She had taken him to two other doctors as well He had not simulated fits in front of any of them He did not know that the second doctor had written to Dr Carr Miss Brown had taken him to the medical board and handed in documents. He had been put in grade 4 , but a year later had been put in grade 3 and had joined the Army. He had since been invalided out for osteomyelitis of the knee He had had a left mastoid He had complained to the doctors of disliking the taste of his medicine , in actual fact he had never had any medicine He had attended the West End Hospital for Nervous Diseases at the end of 1939 Miss Brown had sent him there

I J gave similar testimony Dr Carr had given him luminal and he had taken it for a few days A man accompanied him, purporting to be a relative, and asked for a second opinion , they went to see Dr Konstam and again witness simulated epilepsy. He was then admitted to the East Ham Memorial Hospital, where he continued to feign epilepsy After a week there he felt really ill, and went to see Dr Carr again. He had not simulated a fit He had been put in grade 4 by the Army medical board, but on re-examination he was put in grade 1 He had paid £50 in £1 notes to the man who accompanied him This man had coached him, pretended to be a relative and answered some of the doctor's questions Dr Carr had examined him very thoroughly He had been told to act slow and not to shave

K L testified that Pomeroy had arranged the whole thing for him, and had told him to tell Dr Carr that he had been under a certain doctor who had died. Pomeroy had also provided a man to pose as his brother, accompany him to the doctors and medical board, and answer the questions

M N said that Pomeroy had sent him to Dr Carr at a time when he really was feeling rather ill and shaky He told Dr Carr he had had fits Pomeroy did not think he had been sufficiently trained to go as a full-fledged epileptic, he had had many more lessons before going to Dr Pearse Williams

Q R said his mother opposed his wish to enlist and introduced Pomeroy He saw Dr Carr alone and was thoroughly examined for a fee of 3*s* 6*d* He gave an epileptic history, as instructed He had never had fits He had paid Pomeroy £200 in £1 notes

U V said he had never had any kind of fit He had wanted to go into the Army but had succumbed to pressure He had been sent to Dr Carr by Mr Pomeroy, to whom he had been taken by a business acquaintance He had never had a doctor, Dr Carr had inquired if he had been treated and he had replied that he had, but only when a child He had paid 2*s* 6*d* to Dr Carr and £175 to the business acquaintance, and had visited the doctor again a week later saying he had had another fit At a third visit, a fortnight later, he had asked for a second opinion, he had told the consultant the same story and been thoroughly examined At another visit to Dr Carr he had received a certificate He was accompanied to his medical board by a man produced by Pomeroy Pomeroy's partner Rose had gone with him to the specialist and pretended to be his brother He was graded 4, and 1 at a later board.

Dr Bellingham Smith testified that he had seen K L and honestly believed him to be an epileptic He did not know that his certificate was to be used for an Army medical board He did not think Dr Carr ought to have quoted his confidential opinion in the certificate K L had been accompanied by people claiming to be his father and brother, who had done most of the talking A very complete picture of epilepsy had been presented It was easy to be deceived by one feigning epilepsy Dr Pearse Williams and Dr J Purdon Martin gave similar testimony

Dr Carr said that at the relevant period he was seeing 60–70 patients a day, and many of them came from a distance as a result of evacuation He had had no idea that any of the patients were not genuine The lady described as "Miss Brown's mother" was an old patient of his, taken over from his predecessor Early in 1939 this woman had told him she had a number of mentally defective and very troublesome nephews and grandsons who would not see doctors, and could he help? This was months before C D came to him He had examined C D. very carefully and concluded that he was suffering from epilepsy with mental deterioration He had suggested Dr Konstam as consultant and had written a letter for the relatives to take Dr Konstam had written back fully agreeing with the diagnosis, and suggesting treatment Dr Konstam was now in the Middle East and not available to give evidence Dr Carr had transferred C D to another practitioner because of distance from his surgery

In reply to the President he said that since the war he had given very many certificates of this type—open, in a plain envelope, addressed to nobody in particular

E F (the brother of C D) had been accompanied by the same woman, purporting to be his grandmother, and she had answered most of the questions and given a family history of epilepsy He had sent this case also to Dr Konstam in the same way, and Dr Konstam had written a long clinical report, concluding that E F showed the same condition as his brother, but rather worse E F was transferred to the other practitioner in the same way as C D, enclosing Dr Konstam's letter His fees in all the cases had been 3*s* 6*d* or 2*s* 6*d* and he had never had any other money He believed the certificates might be used for a medical board

G H was brought by the same old lady, as her grandson, and again she answered most of the questions This case had been referred to a physician, on the staff of the London Jewish Hospital, who had written back "What can anyone do for this poor boy? He is a sad specimen . I could get little out of him, but his devoted aunt told me the history " and suggesting treatment He added that a certificate was hardly necessary, as no board would recruit the man, but it should be given by family doctor The "grandmother" had told that he was the family doctor, there was no Witness had asked about previous medical attendance every case Treatment had continued, he believed, the date of the certificate This patient had treated by Dr Worster-Drought at the West End pital without reference to witness, who had been annoyed about it He could not remember why he given two certificates on two successive days

He remembered I J very well, and had treated him some months He gave similar accounts of his with the other witnesses

Counsel on both sides gave addresses, and the after deliberation in camera, announced that the had found all the charges proved and had erased D Carr's name from the Register

In England Now

A Running Commentary by Peripatetic Correspondents

It is remarkable, as one goes on ward rounds, to no how much honoraries vary in their sensitiveness to the reactions of the patient One brilliant man will not permit the mention of tuberculosis, cancer or syphilis, even in a differential diagnosis Another is equally annoyed if you talk about specific infections and Koch's bacillus One of them must be right, though goodness knows which I remember a ward round where we saw a man with aortic incompetence due, as it happened, to atheroma. At the top of his voice, since this was a popular round, the honorary talked about syphilis as the usual cause of this complaint Quite softly, as we walked away, he said that it was not the cause in the case of this particular man What we wanted to know was the effect on that man's status among his friends in the ward —did they, for instance, like using the same bath and cups and newspapers when the non-venereal transmission of syphilis is so widely believed in? And did anyone tell the man himself that it wasn't syphilis? At other times, I must admit, it is the bystanders who are to blame There was once an old lady on whom the gynæcologist was doing a ward round for students and GPs combined He took immense care to talk only of Koch's bacillus in the differential diagnosis "But it might be Pick's disease?" asked one of the GPs "It might," said the gynæcologist unwarily "My aunt died of that," said the GP Some people use their teaching as part of the patient's treatment, telling us the things the patient ought to believe and might not have believed if he hadn't seen us being told them too Others, of course, don't teach at all, but one feels more comfortable with them than with the people who describe the end-picture of heart-failure over a patient who has just realised he has a heart lesion And once we saw an honorary fold his arms over a patient's shoulder and make the most incredible remark ever "When you see," he said, "this dear old lady's lungs on the post-mortem table, as you very shortly will " and he told us what we'd find The end of the story ruins the moral The old lady laughed and laughed, she laughed till she died

* * *

I have just returned from Neo-Slavonia, that small buffer-state created after the last war and still clinging miraculously to its independence in this one Ever since Prince Michael's visit[1] to this country in 1924 Neo Slavonia has become more and more anglicised Not only has it adopted our customs and institutions wholesale, but the very place-names have been modified, and provinces such as Muddlesix and Neitherfolk have a curiously British ring about them

Their tuberculosis problem is acuter than ours in that their general public is aware of it, and it is the general public, or rather one section of it, that has done much to put it on a logical footing by forming a Tuberculous Association Every new patient suffering from tuberculosis automatically becomes a member of the Tuberculous Association and immediately receives a copy of the current *Handbook* Subsequently he receives every issue of the rather sporadic *Bulletin* The association, it seems, only meets as a body once a year for its business meeting The *Handbook* is revised yearly, but much of its contents have remained unaltered for the past ten years It is still laid down, for example (in chapter I), that at the first suspicion of tuberculosis, the patient should at once acquire residential qualification in the province of Muddlesix From time immemorial residence in a parish for three consecutive Sundays has been regarded as adequate for matrimony or judicial hanging, and more recently in a case at law this period of time was adjudged (as the *Handbook* quaintly puts it) "sufficient to cover all shorter-term catastrophies" The advantages gained by pursuing this course are considerable Patients registered in Muddlesix are sent to Muddlesix sanatoria These are smart young go-ahead establishments, whither the best physicians and surgeons are drawn by reason of the excellence of the amenities for treating the disease Every therapeutic adjuvant (such as artificial pneumothorax, phrenic paralysis, thoracoscopy, pneumoperitoneum, thoracoplasty, &c), is in constant application , and new forms of treatment, such as Monaldi drainage, are adopted as soon as their value has been demonstrated elsewhere on the continent The running expenses amount to as much as 4½ golden kröner per patient per week These sanatoria are, of course, crowded out To obviate the disasters attendant upon a long waiting-list, and to encourage the patient who may desire to travel "first class" to health with privacy, luxury cuisine, mountain air or sea breezes, and the companionship of patients of the opposite sex, the province of Muddlesix will pay that 4½ golden kröner towards his upkeep in whatever establishment he chooses to grace so long as he can afford to pay the "difference in the fares"

---

[1] Milne, A A (1924) "To Have the Honour" Wyndham's Theatre

By way of contrast is described the lot of the patient in the province of Fumblefive who, because he wishes to be treated nearer home, or because he is debarred by some technicality from registering in Muddlesix, or because he is bone-stupid, becomes a registered patient in Fumblefive If the diagnosis is ever confirmed (and it may not be unless the sputum is found to be TB positive), his name is put down on the waiting-list of one of the Fumblefive sanatoria, and he will probably be warned that he will have to wait six months for admission Should he be in a hurry to stop getting worse, no obstacle will be raised against his making his own arrangements to go elsewhere , but he won't get a pfennig towards his maintenance there Should he perforce have to go to a Fumblefive sanatorium he must expect to find an establishment between 20 and 25 years behind the times The women's sanatorium has no X-ray plant or weighing machine At the men's sanatorium they have just begun tentatively to tinker with APs (in spite of the Very Senior Physician's prejudice against them) , and this year, the July *Bulletin* informs us, one advanced case was sent away to the local hospital for thoracoplasty, and did not return The expenses at the Fumblefive sanatoria work out at 2½ golden kroner per head per week In the province of Shambleseven things are much the same except that a patient can (by pulling the right strings) extract the 2½ golden kroner a week towards his maintenance elsewhere

More than 50% of the Muddlesix patients are treated with artificial pneumothoraces (Gnirveau and Nocks, 1940), many of which have to be continued after the patient's discharge back to work The *Handbook* (see appendix I) gives a complete list of every refilling station in the kingdom, graded very much as hotels are graded in our British A A Guide

***** *Hengist*, at Hospital, 9–10 AM, 6–7 PM , males, Mon , Wed , Fri , females, Tu , Th , Sat , no queue , asepsis , X ray screen before and after , photo monthly , size 17 needles

* *Horsa*, at Town Hall, 10–10 30 AM , males Tu , females Fri , queue 2 hr , no X rays , peashooters

Private consultants are likewise graded (see appendix II) according to whether they perform their own X-ray and blood sedimentation examinations, or send the patient next door to a 3-kröner radiologist and then round the corner to a 2½-pfennig pathologist

The function of the *Bulletin* is to advise members of important changes and developments in the world of tuberculosis since the last *Handbook* was published , but its most popular columns, without a doubt, are those reporting the "Sayings of the Month" Each of these *mots* must be vouched for by at least three witnesses who were actually present at its delivery, and a small prize is awarded monthly by the associate editors for the one adjudged most memorable The following are a random selection from the July 1942 *Bulletin*

"X-rays ? No by'r lady fear If I had X rays at my sanatorium I'd have to start all this by'r lady AP nonsense"

"I don't believe in sanatorium treatment It's artificial A patient should be treated under the same conditions as regards climate and food as he'll have to live in when he's cured"

"No You can put those X rays back in their folder, madam This (fondling his stethoscope) has been my good friend for more than forty years , and we understand each other"

"Rest, fresh air, and food—especially green vegetables—those will cure any case that can be cured I know that some of these doctors claim marvellous results from their blowings-up and choppings about , but how do they know they wouldn't have got on just as well without them ? Or even better, eh ?"

Theoretically the *Bulletin* is published each month, but in actual practice it is apt to lag behind the months, and the January number may not appear until April In this way it keeps remarkably up to date with the latest news In fact, occasionally it is a little premature No little comment was caused when the obituary notice of Lessij, a Very Senior Physician whose cremation took place in March, appeared in the previous December issue The associate-editors' decision that he had been dead for months and that they were the first to notice it was not well received in some quarters, but had to be accepted as final

* * *

Two more determined social climbers than the verb "to perspire" and its attendant "perspiration" it would be hard to find There was a time when these words were the hall-mark of the genteel but they have now so thoroughly permeated our social system that some doctors, those honest members of the working class, are heard employing them Patients are described in case-notes as "perspiring freely" in the course of his illness or after that line of treatment It is, I suppose, only a matter of time before soldiers due for leave will describe themselves as "perspiring on the top line", or that we shall "don our perspirers" (or should it be perspirators ?) after taking exercise Perspired labour, it is to be devoutly hoped, is a thing of the past, but perhaps some of us may live to hear a refined Hamlet asking "Who would fardels bear, to grunt and perspire under a weary life " I cannot imagine why the Prime Minister did not offer us blood and tears and toil and perspiration

* * *

I have encountered a negation of the well-known fable "Once bitten, twice shy," in my private war against the rodents, and I hasten to present this clinical account in an endeavour to facilitate my promotion to Orthopædist to the Royal Infirmary, Mousehole I occupy a flat designed by its total lack of comforts to keep me always out among my slum patients The mice are thus free to steal my goods by day, and have earned my undying hatred for their noisy gambols by night Being a humanitarian and recognising the virtue of sharing my rations with the lowly creatures, I stopped up their hole with the cork of a bottle of Bristol Cream with which I had intended to celebrate the armistice The pneumatic drilling and noisy bulldozing which occupied them for five nights in reopening the entrance forced me to sterner measures On the first, second and third nights my trap was still set but its cheese had gone I found the secret was to apply a very large lump of cheese to occupy my guests during the long latent period of the trap, and on the fourth night Father mouse was caught across the right upper thigh He moved the trap 16 feet, but then expired His kidney showed the typical histology of "crush syndrome" The fifth night found Aunt mouse caught squarely by the neck and dead Uncle mouse was caught on the sixth night but only by the left knee-joint I got up and found him trying to take his weighty Balkan beam down the hole with him When I applied traction his tail shot straight up like a rocket and with a mighty heave he was gone My trophy was one left leg attached to a deadly engine of war I no longer had the heart to use The seventh and eighth nights read no trap, no sleep, and no bread unsoiled with Gaertner's bacillus in the morning The next night's banishing of my conscience found Sister mouse caught across her bread basket and Baby mouse next night with a clean transection of C4 The eleventh morning revealed a trap undisturbed—did they know my week's rations were exhausted and it was only Thursday? Next Monday, Uncle mouse came shopping again in spite of his three legs and died. My anxiety about having to take up the floor-boards was relieved and I reflected how lucky I was not to have to run such risks to get my daily bread

Letters to the Editor

DIPHTHERIA IMMUNISATION AND THE PUBLIC

SIR,—The important conclusion arrived at in the report of the Committee for the Study of Social Medicine is, as your leader infers, as old as the first general scheme of diphtheria immunisation Though there is almost universal agreement on the urgency of the need for diphtheria immunisation and though most are aware that it is personal contact that counts—as it does in so much of public health work—the organisers of the campaign are able to report only limited success up to the end of last June The next move would seem to lie with the Ministry of Health Collation and circulation of estimates twice yearly to all local authorities irrespective of local government status within circumscribed areas would enable each medical officer of health and each local authority to study the results obtained in their own area in relation to those of their neighbours It might then be discovered that administrative difficulties are playing a greater part in defeating the aim of the organisers of the campaign than has been apparent on the surface For example, has the recent call-up for military service of public health medical staffs affected the position adversely? Is the campaign suffering from insufficiency of local clerical assistance, perhaps the result of disparity in wage rates between local authority temporary staffs and clerical staffs employed in commerce and industry? Is it suffering from delay in filling vacancies in the health visitor staffs due in part to cumbersome local government machinery and in part to a shortage of suitable candidates?

Personal estimates of the proportion of immunised children in an area are not enough Already rumour has it that your peripatetic correspondent knows a man who is prepared to lay odds on the date when the first estimate will exceed 100% The main problem, of course, is diphtheria control, and along with estimated proportions of immunised children there should be issued for each area for each 6-monthly period the numbers of diphtheria notifications and deaths amongst non-immunised and immunised children I believe that circulation of this information would in itself bring more uniformity into local schemes and tend to eliminate the disparity in results existing between adjacent areas It would also provide medical officers of health with valuable local epidemiological information so far not available to them At the same time it might enable us to devote some time and attention to the next campaign—that against whooping-cough

Chadderton J S G BURNETT

SIR,—The valuable survey of public opinion on such an important matter of public health as diphtheria immunisation, carried out by a committee independent of local authorities, has produced evidence and conclusions of which the soundness is attested by medical officers responsible for carrying out diphtheria immunisation, and by the action taken by the Ministry of Health in line with the principal recommendations No doubt members of the committee would agree that though 9 out of 10 mothers gave only one source from which they had heard of the scheme, this would not necessarily be the only factor which had influenced them in making a decision A mother would no doubt remember best the final influence which made her arrive at a positive or negative conclusion, but would forget, or might not even be aware of, previous influences The possible additive effects of influences from all sources should therefore not be forgotten

This might very well be the case, for example, with wireless talks, which appear in the survey to have comparatively little influence There have been three broadcasts this year on diphtheria immunisation on Feb 27, April 22 and Oct 2 I have taken the new cases coming to "open access" clinics in this for a fortnight before the broadcasts, and them with the new cases for the next 4 weeks broadcasts There were very sharp rises shortly the first and third broadcasts The second on April 22, did not have this effect Other local propaganda were fairly constant, and it is not to believe that the rise in the number of new after the wireless talks was more than pure on the two occasions mentioned Assuming that was a boosting factor, the increase depended upon ease with which parents could put their resolutions decisions into effect Though it may be more administratively, the "open access" clinic is much convenient to parents If they know that a clinic is always held on the same day and at the place, and whatever form-filling is necessary can be at the time when the child is brought for then boosting factors such as radio may have more effect than if there is delay in adminis procedure such as fixing an attendance by ap through the post The chief difficulty of "open clinic is that it is impossible to gauge beforehand numbers that will appear, but where there is reason anticipate large numbers (and I have had many with over 200 attendances per session) 2 doctors are in charge of the clinic, and additional attendants provided As the survey says, most mothers are aware of diphtheria immunisation, and local is therefore directed not so much to persuasion as informing parents when and where their children be immunised, acting on the assumption that most them are willing for it to be carried out This can be done with settled clinics on definite days, and handbills all give great prominence to the days times of the various clinics Local circumstances considerably, and what may be successful in one is not necessarily successful in another, but ease of is an important factor, and in densely populated it is advisable to have clinics to serve particular l in much the same way as welfare centres. These be held at welfare centres but I am also using, as doubt many others are, first-aid posts where centres not convenient

The survey method of ascertaining public opinion medical and public health questions seems to be a innovation, and might be used in other directions to help us to take the most promising line of action and to obtain the maximum response from the public

Islington V FREEMAN.

YOUTH PROBLEMS AND MENTAL HEALTH

SIR,—On Oct 13 the Secretary of State for Scotland stated in the House of Commons that 40% of Glasgow's public air-raid shelters had been damaged, doors, lighting, seats and sanitary installations were smashed mostly by youngsters of 14–17 years of age In one district every public shelter was damaged and repaired twice, in 5 other districts four-fifths of the shelters were so treated £70,000 was spent by the corporation for repairs caused through wanton destructiveness by gangs of street urchins The magistrates' committee (*Glasgow Herald*, Oct 14) considered as counter-measures that slides should be shown in cinemas and talks given, that the BBC and the Ministry of Information should be asked to cooperate, and that bills should be posted in factories When somebody asked in Parliament if other big cities had the same difficulties, the answer of the Scottish Secretary was No So much for the boys

The Union of the British Women's Temperance Association discussed, a few days later, the present social problems of Glasgow girls (*Ibid*, Oct 22). One speaker reported on two definite categories the girl under 17, and the older girl who manages to evade the Ministry of Labour in order to prey on Service men These elder ones pass on their identity cards, loiter in the railway stations and spread venereal disease, dodging treatment by escaping from hospital before they are free from infection The younger girls "require something very constructive, definite and kind in the form of a real discipline," said one of the wardens More women policemen and stricter application of the law were among the suggestions of the meeting More street lighting, a curfew for young people and revision of the system of payment of ships' crews were among the remedies proposed at a meeting dealing with the same social evil under the chairmanship of the Lord Provost (*Ibid* Oct 9)

In the causation of this distressing behaviour among the young one recognises the influence of war conditions like the blackout, the absence of paternal control and overcrowding, but war opens up old sores as well as inflicting new wounds Nobody at these meetings seems to have mentioned the question of mental health It is well known that the roving gangs of young riff-raff are often organised by psychopathic or morally defective ringleaders Systematic examination of prostitutes in many countries has shown that the mentally defective and unstable psychopath provide a large proportion especially among those who start their career at an early age Glasgow's mental health services dealing with the detection and treatment of this type of case are —as far as I could find out—inadequate There are 6 child guidance clinics, but only one employs a full-time psychiatrist Five are run by educational psychologists —that is, by a teacher who *only* treats the children by coaching them in subjects in which they are backward He can consult a psychiatrist, but he is responsible for therapy It is as if an orthopædic clinic were run by a chiropodist Of 5 psychiatric outpatient clinics for adolescents and grown-ups only one works on 5 days of the week, the others open on only one afternoon Treatment here is partially in the hands of lay psychotherapists but this may be because of the absence of qualified psychiatrists in the forces The mental-health services themselves are, I gather the same as in peace-time. and how incredibly insufficient they are for a population of nearly 1¼ million Other municipal health services —e g., midwifery—seem well advanced in Glasgow Perhaps the asocial behaviour of juveniles will bring home to those in authority how much their psychiatric services are behind the times but somebody has to let the cat out of the bag

Dumfries W MAYER-GROSS

MEDICAL PLANNING RESEARCH

SIR —May I begin by congratulating MPR on their very fine interim report showing a breadth of view conspicuously absent from certain other reports on the same subject There is one criticism to which a reply is urgently needed The whole scheme rests on compulsory contributions How is the compulsion to be applied? The report suggests only that benefits will be withheld, excluding medical benefits which will continue in any case This means that a man's dependants will be penalised by the withdrawal of the important children's allowances, while he himself will suffer so much from the withdrawal of unemployment benefit that he will be forced to apply for some other form of state help (i e, public assistance), which it would not be possible to deny to him. In other words, if these varied benefits are essential for the maintenance of a proper standard of social life and security, they cannot be withdrawn from the individual and his dependants by way of penalty Does MPR suggest any other method of compulsion? Existing national health contributions are made the responsibility of the employer and not that of the recipient of benefits The employer may even be sent to prison if he does not ensure that cards are properly stamped but he is given a statutory right to deduct the workman's contribution from his wages. The impossibility of extending this arrangement to those who have no employer, and yet earn their own livelihood, together with the equal impossibility of inventing an alternative plan, has hitherto prevented the inclusion of many deserving persons in national health insurance except on a voluntary basis The report implies that it has discovered an alternative method which will prove satisfactory.

Sevenoaks GORDON WARD

LABORATORY TECHNICIANS OF THE FUTURE

SIR,—I read with great pleasure your annotation of Nov 28 on the future status of the laboratory technician A general recognition of the importance of their work and the establishment of their training and subsequent status on a proper basis is long overdue Clinical pathology, one of the youngest medical specialties, has until recently been a neglected child Any odd corner was good enough for the laboratory any converted garden shed—and not always converted—would do for the post-mortem room, and nobody seemed to be interested in the laboratory worker, his training or his future From these dark ages we seem slowly to be emerging, better laboratories and better equipment have everywhere been provided and now at long last the technician's position is to be regularised and improved Much credit is due to the founders and officers of the PBLAA who for many years have worked to this end

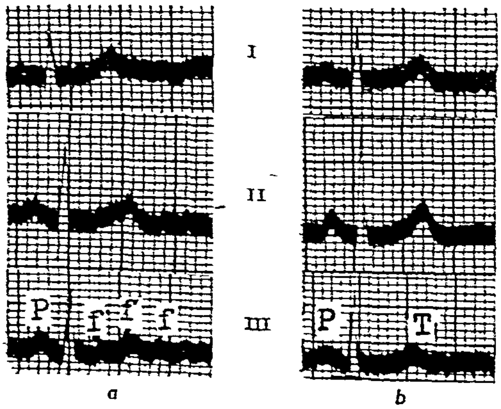
There is one small point on which I should like to comment. The cleaning of glassware is a problem in many laboratories and some employ a cleaner and others rely on the probationary period of the new recruit to solve the difficulty In my experience the former solution where possible, is the better one Although it is important for junior technicians to learn to appreciate the meaning of "clean glassware"—not always so simple for the ex-schoolboy—they should certainly not be sentenced to the sink for months or years on end which is inevitable when a vacancy above them is not likely to occur for some time Surely there is a more economic way of selecting candidates than by estimating their suitability in decibels of crashing glassware. If this work is to attract the better educated boy which the suggested curriculum will demand, these routine menial probationary duties must be reduced to a minimum It will indeed be an advance when it is possible to offer the prospective technician not only an occupation of exceptional interest but also an established position with a better financial reward and the prospect of obtaining the qualifications of a chartered society

Kent and Canterbury Hospital NORMAN H ASHTON

ELECTROCARDIOGRAM IN TRAUMA OF THE HEART

SIR,—As a supplement to your annotation of Oct 31 the following case may be of interest

A man of 48 sustained an injury to his chest wall as a result of his spectacle case being driven on to the costochondral junction just below the left nipple When he was first seen two days later he had pain on pressure over the site of injury and this was also produced on breathing or coughing No fracture was shown by X ray Although the patient stated that he had previously been in good health, the X ray suggested an enlarged aortic arch and an electrocardiogram was taken (*a* in figure) This showed f waves in lead III although normal P waves were present, it also showed complete irregularity of rhythm Another electrocardiogram three days later (*b*) showed no f waves although arrhythmia remained The differential diagnosis between auricular flutter and fibrillation was not easy, but after consultation with Dr Peter Miles it was decided that the curve was an example of fibrillation



a *b*

It is interesting to note how signs and symptoms of rib damage might mask those of myocardial trouble, and the value of an electrocardiogram in such a case is obvious

Manchester Square, W 1 H W HALES

CÆSAREAN SECTION AND THE CRUSH SYNDROME

SIR,—I am gratified to learn that Mr Milne allows that spinal anæsthesia has a place in obstetrics In view of his opinion that asepsis can never be assured in midwifery practice, it is difficult to understand why he should hang his head in shame when pyrexia, white leg or embolism may have occurred on rare occasions in his practice It is true that I had an unbroken series of successes for ten years, but only a few more than fifty patients were concerned, and perhaps the incidence of white leg and embolism in forceps delivery under the worst conditions would scarcely show itself with such a number Since the outbreak of war I have had three severe infections. in one neither spinal nor forceps was used, but of the other two patients one died A friendly or well-paid counsellor might argue that the conditions imposed by the state of war had been contributory, in any case, Mr Milne may content himself on learning that he does not hold a monopoly of the head-hanging business

Being by nature perverse, I attributed the excellence of my results—obviously due to good luck and the paucity of material—to the limitation of fatigue in the patient, to the use of chlorine, to the early and brief starvation and curtailment of fluid Mr Milne, in his brilliant criticism, does not refer to the effect of fatigue, he does not mention the use of chlorine or of any other antiseptic in obstetrics, but his opinion that starvation and fluid restriction is "unphysiological" has caused me to think—and to write—quite a lot Sometime I may be able to publish a dissertation on this interesting criticism At the moment, I remain incorrigible, but I leave Mr Milne master of the field If permitted, however, I would advise Mr Milne to read, or re-read, Semmelweis's practice with parturient women If washing the hands in chlorine diminished the incidence of puerperal fever, perhaps the application of the same stuff to the pudendal region and to the genital canal, and the knowledge that vaginal hysterectomy can be performed without sepsis, may cause him to alter his view that asepsis in midwifery is impossible

Rugby R H PARAMORE

TIME AND THE SECOND M B

SIR,—In connexion with the article on the second MB by Prof Samson Wright (*Lancet*, Oct 3, p 405) may I suggest the following revised first-year biology course Assuming that the work of the first year should be a preparation for human anatomy and physiology in the same way that those subjects are a preparation for clinical studies, and assuming also that elementary biology should be taught in schools as a part of general education, the time available for biology in the first year could be used as follows

I One term of lectures and dissection, on the comparative anatomy of vertebrates from the point of view of mammalian evolution This could be based as at present on the dogfish, rabbit and the development of the fowl, but studied more thoroughly and with more emphasis on applications to human anatomy

II One term of lectures and practical work on elementary physiology as an introduction to human physiology and to experimental method.

III The whole of the histology course, also occupying one term, as at present taught in the second year

The examination could consist of written questions on parts I and II with a practical examination in dissection, identification of specimens and comment on experiments, and also a practical examination on histology like that which already forms part of the second MB

This arrangement would save time directly because part of the second year's work would be done in the first year, and indirectly because all the time would be spent on work having a direct bearing on the work of succeeding years It would be more successful than the existing course in arousing and holding the attention of the student Time would thus be saved for that extra teaching which, as Professor Wright points out, modern physiology demands A few lectures on genetics could best be given in conjunction with lectures on the so-called inheritable diseases in the later years of the curriculum

University of London J H WOODGER

GRANULES IN PUS CELLS

SIR,—Your friendly annotation of Dec 5 (p 67 reads more into my short paper on granule movement pus cells (*Brit J exp Path* 1942, 23, 188) than contains, crediting me by inference with ideas I do hold In its final sentence you write "Hope Sim concludes that Brownian movement cannot explain patently vital a phenomenon as this granular turbulence it is something more, he thinks, than a mechan consequence of the colloidal nature of the cytoplasm, is in some way an expression of the individual propert of the granulocyte" May I make it clear that I do consider granule movement a patently vital phenomen nor do I think it is in some way an expression of individual properties of the granulocyte? I am sure that I understand the meaning of such expressions It is said that the granules of certain protozoa and some cells exhibit Brownian movement—a reasonab enough statement The movements of certain protozo probably depend on local reversible gelation of th colloidal cytoplasm Immobilisation of the granule has been taken as evidence of such gelation Irreversibl gelation of the cytoplasm is said to occur at cell death and the immobilisation of all the granules is cited a part of the evidence This conception has sometime been invoked to explain the behaviour of leucocytes, and my paper was concerned to show that because the granule motility of the granulocytes is not Brownian the theory cannot be applied to leucocytic behaviour without closer scrutiny, and further that in granulocytes immobilisation of the granules at cell death often occurs without cytoplasmic gelation The cause of granule motility in pus cells may not be far to seek It may be a matter of the influence of osmotic activity through the cell membrane or of the peculiar surface forces operating on bodies of the small size of pus-cell granules It appears, however, not to be Brownian movement, and theories basing evidence on this supposition need to be reconsidered

Beaminster R E HOPE SIMPSO

Obituary

GEORGE NOEL BRAHAM

O B E, M C, F R C S E

Professor Braham has died at the age of 56 in Bagdad where he had been living for many years Educated at the Victoria University of Manchester he took his triple qualification in 1909 and the Edinburgh fellowship in 1913 Immediately on the outbreak of the last war he joined up and served through the Mesopotamian campaign where he won the MC and was awarded the OBE After the war he elected to stay on and take a part in building up the new country of Iraq, and of all the Englishmen who shared in this work there was none so popular, nor so esteemed by the Arabs, as George Braham He became chief surgeon to the Anglo Persian Oil Company and returned for a while to practise surgery in Southampton and Gosport, but the desert lured him back to Abadan in Persia

When some fourteen years ago that progressive and far-sighted man, King Feisal, founded the Royal College of Medicine in Bagdad, with a nucleus of British professors assisted by Iraqis, he invited Braham to take the chair of surgery Later Braham operated on the King and received from him the Iraqi order of Al Rafidain A little before trouble broke out in Syria Braham had retired to the Lebanon coast but when hostilities started he was forced to return again to Bagdad He was a skilful diagnostician and an able surgeon and had the invaluable gift of imparting some of his cheerful confidence to his patients so that an impending operation lost much of its terrors He was a delightful companion and a witty raconteur, full of that kindly cynicism peculiar to the observant man of the world, but he never bore anyone ill will Braham had a highly developed if somewhat eclectic literary taste, and he enjoyed nothing more than sitting under the palms in his garden talking about the books of the last century

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS, MP

The debates on the King's Speech are over and in the two final debates, one on the amendment moved by Mr Greenwood and the other on that moved by the ILP group, the House got down to important principles The ILP with its three members led by Mr Maxton could only muster five supporters because it rather turns away from the world and as Mr Attlee says lives in an ivory tower of dreams But the ILP amendment did at least indicate the right of any minority to be heard, and that is fundamental for the work of our democratic parliament The Speaker is careful to maintain this right so that it sometimes seems that the dissident minority have a greater opportunity of airing their views than the official cohorts of the majority parties Mr Greenwood for the Labour Party and Sir William Jowett for the Government both referred to the need for international security against war as the pre-requisite of the large-scale planning of a better world But Mr Eden made it more definite and did indeed devote more time to foreign policy than either of the two main speakers before him "What will happen when the fighting is over," said Mr Eden, "is that these Great Powers, and particularly ourselves, the United States and Russia, will have a virtual monopoly of armed strength, and that armed strength must be used in the name of the United Nations to prevent a repetition of aggression" But it was essential that the independence of smaller nations should be restored and secured; "in any world system that is to operate all states will have to play their part"

The problem of the immediate relief work in Europe, and elsewhere, which will fall to be done when the Cease Fire sounds, came up for discussion, but only in a preliminary way The original proposal of the meeting of representatives of the United Nations, held at St James s Palace in September 1941, was that a fact-finding committee, with Sir Frederick Leith-Ross as chairman, should assess the needs of the nations of Europe Something seems to have gone amiss with this project No report of the committee has been published, and apparently no report has been submitted to a meeting of representatives of the United Nations, for no meeting has been held since September of last year The programme was upset by the Japanese attack in the East Our own resources of food and materials have been largely used up The responsibility for accumulating new reserves falls on our Dominions and on the USA The recent announcement that Mr Lehman, retiring governor of New York, has been appointed by President Roosevelt to organise American participation in these relief activities has given rise to speculation as to what coördination of relief responsibilities by the United Nations does in fact exist The problem of control and coordination, on the political side evidently needs some reconsideration and Parliament may be expected to turn its attention in this direction in the New Year

The headline sensation of the week was the publication of the Beveridge report The guarantee of financial security for all classes from birth to death has captured the support of a majority of members of all parties The fact that the scheme almost incidentally assures a more or less complete nationalisation of the medical services and institutions is accepted as if it were already an accomplished fact The report as a whole is to be considered in the New Year so that it looks as if Parliament will be very busy laying the foundations of the new world in 1943

FROM THE PRESS GALLERY

Rational Rationing

Speaking on the Government's plans for postwar reconstruction in the debate on the King's Speech on Dec 1, Sir William Jowitt explained the brevity of his remarks on health by saying that the Minister of Health had under active review all the health and hospital services of this country Mr Brown had made one statement not long ago, and in due course he would doubtless have something further to say Sir William confined himself to the question of food policy and nutrition Surely, he claimed, we had learned something about these matters during the war The Ministry of Food had built up an organisation which distributed the nation's food so as to secure the proper feeding of all classes to a degree never before achieved Means had been devised for getting the food to the people in the best condition, in the right proportions, with a minimum of waste and with little regard to the extent or the size of the consumer's income We had acquired what was perhaps more important than any piece of administrative mechanism—a new sense of corporate responsibility We were satisfying the basic needs of even the humblest individual citizen Never before had so much attention been given to the food requirements of mothers and young children as in these war years But thoughtful people asked, "Is it only in a period of war that special priorities are to be provided for workers, mothers, young children and infants? Is it conceivable that what has been done to keep our people in good health and good heart in a period of food shortage shall cease to be done when supplies become abundant again?" Sir William said he could not believe that the wise development which had taken place in the last few years would be abandoned after the war was over

Health of the Colonies

Viscount Cranborne, until recently Secretary of State for the Colonies, made a spirited defence of British administration in the Colonial Empire in a speech in the House of Lords on Dec 3 Education and health, he said, in many ways went together In medicine also we needed the mass attack, and for it we required a trained staff supplied by the Colonial peoples themselves Medical schools were at work in East and West Africa, in Ceylon, Malta and Fiji, turning out doctors Nurses and medical auxiliaries were being trained Hospitals were being constructed or enlarged Investigations of the utmost value were being carried out by our own organisations and by the Rockefeller Foundation. Slowly but steadily the problems of malaria, yellow fever, venereal disease, malnutrition and tuberculosis were being tackled And in this connexion Lord Cranborne paid a tribute to the work of the Colonial Medical Service, who in remote, unhealthy, fever-ridden districts were giving their lives for the welfare of the native populations After education and health the third great need was social and economic security Here again while the war had created difficulties it had speeded up the production of food for local use, and this should have a permanent effect in raising the standard of living in many Colonies It had stimulated action towards greater self-sufficiency in local food supplies and an interest in the development of mixed farming It was to be hoped that the progress made would be consolidated after the war

QUESTION TIME

Medical Inspection of School-children

Mr D L Lipson asked the President of the Board of Education he if would withdraw circular 1604, which recommended the curtailment of medical inspection of children in elementary schools so that there would be no routine medical examination of school children from their entry to school at five years of age until their last year of school life —Mr R A Butler replied The medical man-power position has necessitated the recommendations made in the circular In some areas the staff is insufficient to carry out the full programme of medical inspection Mr Lipson Is the Minister aware that some local authorities believe that regular medical inspection is as necessary in war time as in peace, and have the staffs to do so? Is the intention of the circular that more school medical officers will be called up for military service? Sir Francis Fremantle Is it not a fact that nurses and teachers can exercise extremely good supervision over the children, and that there is probably very little difference in the routine? —Mr Butler There is special reference in the circular to the work that nurses can do, and I hope that they will take the work up It is not the object of the circular to make the service more restricted, but to make the best use of the man-power available I undertake to do my best for the service in war time conditions Mr Lipson Will the Minister undertake to prevent more medical officers being called up? —Mr Butler I have said that I will do my best, but I must donors has been used for serum production for civilian needs In addition there has been a drive to provide pooled serum for the Services and for possible civilian air-raid casualties, as a result there have been 11,397 calls for donors as compared with 2955 in the previous year The laboratory work of testing donors is carried out almost entirely at the Hall Institute of Research The hæmoglobin content of the blood of donors who have repeatedly given blood has been examined, and in a small percentage of 3330 tested the original hæmoglobin level has not been maintained These have been notified and have responded to adequate iron therapy

Royal College of Physicians of Edinburgh

The annual meeting of the college was held on Dec 3 Dr Charles McNeil was re elected president and Dr L H F Thatcher, Dr A Murray Drennan, Dr A Fergus Hewat, Dr D M Lyon, Dr A Graham Ritchie and Dr A Rae Gilchrist were elected to form the council of the college for the ensuing year Dr A Fergus Hewat was nominated vice president

Faculty of Radiologists

The following candidates have satisfied the board at the examination for the fellowship of the faculty —

Radiodiagnosis —G Friedlaender
Radiotherapy —I G Williams

Royal Society of Medicine

At 2 15 PM on Wednesday, Dec 16, at the section of comparative medicine Dr A W Downie, Dr H J Parish and Mr R Lovell, PhD, will open a discussion on bacterial vaccines and toxoids On Dec 17, the section of neurology will meet at 3 30 PM when Prof V P Sydenstricker and Dr H M Sinclair will be the opening speakers in a discussion on neurological complications of malnutrition

Medical Casualties

The following casualties among RAMC officers have been announced

Wounded —Captain R D I Beggs, MB CAMB, W S/Captain P T Savage, MB LOND

Prisoners of War —WS/Captain R W Doyle, FRCS, WS/Captain B F B Gulliver, MC, MB LOND, A/Major Turner McLardy, MB GLASG, WS/Captain John McQuillan, MB DUBL, and Captain F J D Webster, MB LEEDS

Dr N A D Sharp, late SMO in the West African medical service, is reported to be " missing believed killed " on active service during October

Medical Honours

The George medal has been awarded to Flying Officer J A Elliott, MRCS, RAFVR

In May a Boston aircraft crashed shortly after taking off from an aerodrome and burst into flames An airman who was on duty near by hastened to the scene, where he was joined by five soldiers Although the fire was intense and ammunition was exploding in all directions, one member of the crew (the air gunner, who was seen to be hanging out of the turret) was dragged from the wreckage by one of the soldiers, and then, with the assistance of the remainder of the party, carried on a stretcher to an ambulance The party was returning to the aircraft, which was then being approached by the station engineer officer and Flying Officer Elliott, when a bomb exploded The engineer officer was thrown to the ground bleeding from the chest Elliott, although also knocked down, was uninjured and immediately went to the aid of the engineer officer He gave him morphia and at the time was fully aware that other bombs were in the aircraft only eight yards away A second bomb exploded which wounded Elliott, but he valiantly attempted to remove his injured comrade Eventually Elliott was assisted away by one of the soldiers, while the remaining men of the party removed the engineer officer, who was found to be dead Throughout Elliott displayed great determination and complete disregard for his own safety

---

A sterile preparation of sulphanilamide is now issued by Burroughs Wellcome and Co as ' Wellcome ' brand Sterilised Sulphanilamide Compound This is a free flowing, mobile powder consisting of finely divided sulphanilamide with 5% of zinc oxide The zinc oxide is added to facilitate complete sterilisation without aggregation of the sulphanilamide particles, and also to retard absorption of the compound so as to prolong local chemotherapeutic action The product is issued in bottles of 15 grammes

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Infectious Disease in England and Wales

WEEK ENDED NOV 28

Notifications —The following cases of infectious were notified during the week smallpox, 0, fever, 2970, whooping-cough, 1263, diphtheria, paratyphoid, 4, typhoid, 13, measles (excluding ella), 10,649, pneumonia (primary or influenzal), 7 puerperal pyrexia, 161, cerebrospinal fever, 77, myelitis, 18, polio-encephalitis, 6, encephalitis argica, 1, dysentery, 163, ophthalmia neonat 82 No case of cholera, plague or typhus fever notified during the week

The number of civilian and service sick in the Infectious of the London County Council on Nov 25 was 1947, scarlet fever, 725, diphtheria, 258, measles, 241, wh cough, 167, enteritis 97, chicken pox, 54, erysipelas, 44 mumps, 38, poliomyelitis, 3, dysentery, 48, cerebrospinal 7, puerperal sepsis, 24, enteric fevers, 8, german measles, 1

Deaths —In 126 great towns there were no deaths enteric fevers, 2 (0) from scarlet fever, 10 (1) from me 13 (2) from whooping-cough, 17 (0) from 36 (5) from diarrhœa and enteritis under two years, 35 (7) from influenza The figures in parentheses are those for London itself

Liverpool reported 4 deaths from whooping cough *There were 6 fatal cases of diarrhœa at Birmingham*

The number of stillbirths notified during the week was 188 (corresponding to a rate of 33 per thousand total births), including 7 in London

Appointments

CRAIG, A J, MD MALTA, FRCS temp surgical officer at Southport General Infirmary
ELLIS, FRANK, MB SHEFF, FFR radiotherapist to the London Hospital
GLASGOW, J E, MB BELF, DMRE senior asst MO to the radiological department of Manchester Royal Infirmary
JAIDKA, K C, FRCSE surgeon to the Peterborough and District Memorial Hospital
MURRAY, J BARRIE, MB CAMB, MRCP temp physician to the Bolingbroke Hospital
THOMAS, CHARLES, MD TORONTO surgical registrar at the Coventry and Warwickshire Hospital
VENTERS, MARGARET, MB EDIN, MRCOG, MMSA temp (joint) obstetric officer for Barrow in Furness
* WAKEMAN, A C R, MRCS, DMRE whole time radiologist to the Cardiff Royal Infirmary
WILSON, EILEEN, MD LOND asst obstetrician for maternity unit at Epsom County Hospital
WORMALD, HUGH, MB LOND, DMRE junior asst MO to the radiological department of Manchester Royal Infirmary

* War time appointment

Births, Marriages and Deaths

BIRTHS

FRANKLIN —On Dec 2, in London, the wife of Dr John Franklin—a son
GALLEY —On Nov 28, in London, the wife of Dr A H Galley—a son
MAYON WHITE —On Dec 1, at West Lulworth, Dorset, the wife of Dr R M Mayon White—a son
ROBERTS —On Dec 2, in London, the wife of Mr J L Digby Roberts, FRCS—a son
STEVENSON —On Dec 2, at Derby, to Dr Patricia Stevenson (née Cooper), wife of Surgeon Lieutenant G D Stevenson, RN—a daughter
TISDALL —On Nov 29, at Sutton, Surrey, the wife of Dr Gerard Tisdall—a daughter

MARRIAGES

BLACK—ALLEN-WILLIAMS —On Nov 28 in London Walter Rutherford Black, FRCSE, to Gwendolen Mary Allen Williams, MB
BROWN—HOWELL —On Dec 1, at Neath, Donald Brown, MRCS surgeon lieutenant RNVR, to Gweneth Howell, MB
CRAIL—PETTY —On Dec 2, at Worle Robert Brownfield Crail, lieutenant RAMC, to Ellen Margaret Petty
JONES—BEATTIE —On Nov 26, at Formby, Walter John Jones MB, lieutenant RAMC, to Jessie Jane Haig Beattie, MB, lieutenant RAMC
LOVETT DOUST—ATKINSON —On Nov 28, at Oxshott, John William Lovett Doust, MB, to Meriel Atkinson

DEATHS

CANDLER —On Dec 4, John Pycock Candler, MD CAMB, DPH, of Brampton, Hunts
HARVEY —On Dec 2, Alexander William Montgomery Harvey, CB, MB EDIN, major general IMS retd, of Merrow, Guildford
HOWARD —On Dec 2, at Oving, Bucks, Russell John Howard CBE, MS LOND, FRCS, aged 67
STEWART —On Nov 29, at Beckenham, Frederick William Stewart, MD RUI
TUCKETT —On Nov 28, Ivor Lloyd Tuckett, MD CAMB, of Cowes I W, fellow of University College, London, late fellow of Trinity College, Cambridge, aged 69

EMOTIONAL AND COGNITIVE CHANGES IN THE POST-TRAUMATIC CONFUSIONAL STATE *

ANDREW PATERSON, M D EDIN, D PSYCH

(*From the Brain Injuries Unit, Edinburgh*)

THE most important function of the human brain is the maintenance of mental activity and conscious behaviour Psychology studies mental processes but has been handicapped because those processes compose a unity, the mental life of the individual, from which it has been impossible to isolate one component and subject it to separate study In certain brain lesions however this complex system of interrelated functions breaks down and the various components disintegrate selectively according to the site of the lesion, Nature herself providing an analysis To study the function of speech one investigates its breakdown and recovery after cerebral lesions In normal speech there is a general background of syntax and grammar this is grossly impaired by lesions in the temporo parietal area of the cortex, and this background is rendered inaccessible for the aphasic patient Lesions of the occipito-parietal area give rise to acalculia, the system of arithmetical principles being inaccessible Lesions somewhere in the region of the third ventricle are liable to disturb the wider background of spatial and temporal relationships The same rule of breakdown and recovery after cerebral lesions applies to the other higher cerebral functions, memory and orientation, perception and imagination, and maintenance of emotional attitudes and stable behaviour patterns

We owe this psychiatric approach to Hughlings Jackson, and its detailed working out in respect of individual mental functions, speech, local spatial orientation and many others to his disciple Henry Head and his successors in that school Jackson's concept of insanity as the pathological dissolution or breakdown of ordinary mental functioning is too often lost sight of in the exuberance of present-day psychopathological theory

We have investigated in detail all our cases of gross confusion arising from any cause, the commonest being severe concussional brain damage In those cases we see the breakdown of conscious activity in its most severe and therefore simplest form We have traced the gradual reinstatement of the various functions which constitute it and have studied the finer defects remaining when the patient has returned to his ordinary routine activity Thus a background of experience is being built up of the course, management and disposal of these cases In the past the psychiatrist has often been called in to see only the end-results in the mental sphere of organic brain damage The patient with impaired cerebral function has by that time become a nuisance to himself to his employers and probably to the neurologist and neurosurgeon His trouble is diagnosed to be one of personality. This is too often conceived of as some ethereal entity having a nature and existence apart from the brain, rather than as the pattern of individual behaviour which the functioning of the brain makes possible Knowledge gained from a study of the course of the post-traumatic psychosis throws light on this difficult syndrome

Goldstein has made extensive studies of the disintegration of mental function after many types of cerebral lesion and has extended the teaching of the *Gestalt* school of psychology to account for many of the phenomena exhibited Symonds [1] has summarised the principles formulated by Goldstein thus

> The essence of every mental event is the formation of a figure which stands out in relief against a background In every thought process there is an active tendency towards such figure formation The tendency is to select from a mass of more or less suitable material those elements which are suitable for the precise figure formation and to reject those elements which are unsuitable The rejected elements form the background As the final result we have the figure standing out in relief against a background of related but irrelevant material As the result of disease, the selective action breaks down The formation of a precise figure is then interfered with by the emergence of loosely related material from the background The attempt at thinking, therefore, can only result in a blurred figure formation

In the confusional state there are restriction of the conscious field and inaccessibility of the background The various stages through which the confused person passes towards recovery consist in the widening of the conscious field and the increasing accessibility of the background, or perhaps of the different types of background Restriction of the conscious field in confusion has been noted by many writers, but its course through the various stages of recovery has not always been traced As the principles of *Gestalt* psychology spring from consideration of the cognitive aspect of conscious experience, and more particularly from visual perception, Goldstein and his followers have tended to interpret confusion in cognitive terms as the blurring of figure and ground I shall try to show however that emotional attitudes involved in all confusional states are distorted in a way analogous to the restriction of the cognitive attitudes and that the interferences in the two fields enhance and reinforce each other

COGNITIVE FEATURES IN THE CONFUSIONAL STATE

CASE 1 —A petty officer, aged 40, was admitted to hospital a week after having fallen 30 ft on to his head There was no fracture of the skull He was grossly disoriented in time and did not recognise that he was in hospital or that the nurses were nurses , he regarded them as his sisters and the doctors as his shipmates His mood was changeable, mainly irritable, querulous and petulant, but at times genial and elated A paraphasic disorder of speech was apparent He was mildly hallucinated, imagining that a mole and a stickleback were in his bed At times he would deny that he was in bed, though lying there When he was asked the name of a silver pencil he stated that it was a cigar Asked what he would do with it, he put it in his mouth and tried to smoke it , he treated the tapered end of the pencil as the end of a cigar To confirm this I lit a match near him and turning towards the light he put the other end of the pencil in the flame and puffed vigorously In this case, the patient saw one aspect or quality of the pencil, namely, that it was long with a tapered end He saw this in isolation from its colour and from the other end which was large and had a clip on it All the qualities of the pencil except the tapered end were somehow suppressed, or at least not active in determining its nature for him We see here one of the most important principles in the breakdown of the conscious process, namely, restriction of the field to one or two characters or qualities and the shutting out of other—perhaps intimately associated—qualities Another example of this process occurred when he complained that a shipmate had on a recent visit committed a serious sexual offence against him Some would regard this allegation as arising from repressed infantile tendencies taking advantage of the man's confused mind Actually the night staff, in spite of vigorous protests, had given him an enema As in the previous example, he failed to see the situation as a whole and appreciated one aspect of it only

CASE 2 —During an interview with a patient who was in a mildly disoriented state after severe confusion, one of the department's therapists wearing a white coat knocked and opened the door The immediate response was " A couple of beers please, miss " The patient had seized on three features of the situation only, the warm day, the bare room and the girl in the white coat, and immediately assumed that he was in a bar, ignoring, for the moment, all evidence to the contrary

The scope of ordinary conscious process goes beyond the main subject of attention, or, in terms of *Gestalt* psychology, the figure Any perceived object owes its significance to a greater or lesser extent to the setting in which it appears For example, given a bone surrounded by flesh and a saw, the observer cannot come to a definite conclusion as to their precise significance When the setting of an operating theatre, post-mortem room or butcher's shop is added, however, this immediately becomes apparent In this case the object isolated from its surroundings, has little meaning , its significance depends on its spatial relationships Although they are not consciously attended to these spatial relationships modify and determine the full meaning of the object donors has been used for serum production for civilian needs In addition there has been a drive to provide pooled serum for the Services and for possible civilian air-raid casualties, as a result there have been 11,397 calls for donors as compared with 2955 in the previous year The laboratory work of testing donors is carried out almost entirely at the Hall Institute of Research The hæmoglobin content of the blood of donors who have repeatedly given blood has been examined, and in a small percentage of 3330 tested the original hæmoglobin level has not been maintained These have been notified and have responded to adequate iron therapy

---

* A paper read to the Society of British Neurological Surgeons on Aug 2 1942

[1] Proc R Soc Med 1937 30 1081

Royal College of Physicians of Edinburgh

The annual meeting of the college was held on Dec 3 Dr Charles McNeil was re elected president and Dr L H F Thatcher, Dr A Murray Drennan, Dr A Fergus Hewat, Dr D M Lyon, Dr A Graham Ritchie and Dr. A Rae Gilchrist were elected to form the council of the college for the ensuing year Dr A Fergus Hewat was nominated vice president

Faculty of Radiologists

The following candidates have satisfied the board at the examination for the fellowship of the faculty —

Radiodiagnosis —G Friedlaender
Radiotherapy —I G Williams

Royal Society of Medicine

At 2 15 PM on Wednesday, Dec 16, at the section of comparative medicine Dr A W Downie, Dr H J Parish and Mr R Lovell, PhD, will open a discussion on bacterial vaccines and toxoids On Dec 17, the section of neurology will meet at 3 30 PM when Prof V P Sydenstricker and Dr H M Sinclair will be the opening speakers in a discussion on neurological complications of malnutrition

Medical Casualties

The following casualties among RAMC officers have been announced

Wounded —Captain R D I Beggs, MB CAMB, WS/Captain P T Savage, MB LOND

Prisoners of War —WS/Captain R W Doyle, FRCS, WS/Captain B F B Gulliver, MC, MB LOND, A/Major Turner McLardy, MB GLASG, WS/Captain John McQuillan, MB DUBL, and Captain F J D Webster, MB LEEDS

Dr N A D Sharp, late SMO in the West African medical service, is reported to be " missing believed killed " on active service during October

Medical Honours

The George medal has been awarded to Flying Officer J A Elliott, MRCS, RAFVR

In May a Boston aircraft crashed shortly after taking off from an aerodrome and burst into flames An airman who was on duty near by hastened to the scene, where he was joined by five soldiers Although the fire was intense and ammunition was exploding in all directions, one member of the crew (the air gunner who was seen to be hanging out of the turret) was dragged from the wreckage by one of the soldiers and then, with the assistance of the remainder of the party, carried on a stretcher to an ambulance The party was returning to the aircraft, which was then being approached by the station engineer officer and Flying Officer Elliott, when a bomb exploded The engineer officer was thrown to the ground bleeding from the chest Elliott, although also knocked down, was uninjured and immediately went to the aid of the engineer officer He gave him morphia and at the time was fully aware that other bombs were in the aircraft only eight yards away A second bomb exploded which wounded Elliott, but he valiantly attempted to remove his injured comrade Eventually Elliott was assisted away by one of the soldiers, while the remaining men of the party removed the engineer officer, who was found to be dead Throughout Elliott displayed great determination and complete disregard for his own safety

---

A sterile preparation of sulphanilamide is now issued by Burroughs Wellcome and Co as ' Wellcome ' brand Sterilised Sulphanilamide Compound This is a free flowing, mobile powder consisting of finely divided sulphanilamide with 5% of zinc oxide The zinc oxide is added to facilitate complete sterilisation without aggregation of the sulphanilamide particles, and also to retard absorption of the compound so as to prolong local chemotherapeutic action The product is issued in bottles of 15 grammes

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Infectious Disease in England and Wales

WEEK ENDED NOV 28

Notifications —The following cases of infectious di were notified during the week smallpox, 0, sc fever, 2970, whooping-cough, 1263, diphtheria, 861 paratyphoid, 4, typhoid, 13, measles (excluding ella), 10,649, pneumonia (primary or influenzal), 766 puerperal pyrexia, 161, cerebrospinal fever, 77, po myelitis, 18, polio-encephalitis, 6, encephalitis le argica, 1, dysentery, 163, ophthalmia neonator 82 No case of cholera, plague or typhus fever notified during the week

The number of civilian and service sick in the Infectious Hospit of the London County Council on Nov 25 was 1947, inclu scarlet fever, 725, diphtheria, 258, measles, 241, whoopi cough, 167, enteritis, 97, chicken pox, 54, erysipelas, 4 mumps, 38, poliomyelitis, 3, dysentery, 48, cerebrospinal fe 7, puerperal sepsis, 24, enteric fevers, 8, german measles, 1

Deaths —In 126 great towns there were no deaths fro enteric fevers, 2 (0) from scarlet fever, 10 (1) from measl 13 (2) from whooping-cough, 17 (0) from diphther 36 (5) from diarrhœa and enteritis under two years, an 35 (7) from influenza The figures in parentheses are those for London itself

Liverpool reported 4 deaths from whooping cough There were 6 fatal cases of diarrhœa at Birmingham

The number of stillbirths notified during the week was 188 (corresponding to a rate of 33 per thousand total births), including 7 in London

Appointments

CRAIG, A J, MD MALTA, FRCS temp surgical officer at Southport General Infirmary

ELLIS, FRANK, MB SHEFF, FFR radiotherapist to the London Hospital

GLASGOW, J E, MB BELF, DMRE senior asst MO to the radiological department of Manchester Royal Infirmary

JAIDKA, K C, FRCSE surgeon to the Peterborough and District Memorial Hospital

MURRAY, J BARRIE, MB CAMB, MRCP temp physician to the Bolingbroke Hospital

THOMAS, CHARLES, MD TORONTO surgical registrar at the Coventry and Warwickshire Hospital

VENTERS, MARGARET, MB EDIN, MRCOG, MMSA temp (joint) obstetric officer for Barrow in Furness

* WAKEMAN, A C R, MRCS, DMRE whole time radiologist to the Cardiff Royal Infirmary

WILSON, EILEEN, MD LOND asst obstetrician for maternity unit at Epsom County Hospital

WORMALD, HUGH, MB LOND, DMRE junior asst MO to the radiological department of Manchester Royal Infirmary

* War time appointment

Births, Marriages and Deaths

BIRTHS

FRANKLIN —On Dec 2, in London, the wife of Dr John Franklin—a son

GALLEY —On Nov 28, in London, the wife of Dr A H Galley—a son

MAYON-WHITE —On Dec 1, at West Lulworth, Dorset, the wife of Dr R M Mayon White—a son

ROBERTS —On Dec 2, in London, the wife of Mr J L Digby Roberts, FRCS—a son

STEVENSON —On Dec 2, at Derby, to Dr Patricia Stevenson (née Cooper), wife of Surgeon Lieutenant G D Stevenson, RN—a daughter

TISDALL —On Nov 29, at Sutton, Surrey, the wife of Dr Gerard Tisdall—a daughter

MARRIAGES

BLACK—ALLEN WILLIAMS —On Nov 28, in London Walter Rutherford Black, FRCSE, to Gwendolen Mary Allen Williams, MB

BROWN—HOWELL —On Dec 1, at Neath Donald Brown, MRCS, surgeon lieutenant RNVR, to Gweneth Howell, MB

CRAIL—PETTY —On Dec 2, at Worle, Robert Brownfield Crail, lieutenant RAMC, to Ellen Margaret Petty

JONES—BEATTIE —On Nov 26, at Formby, Walter John Jones MB, lieutenant RAMC, to Jessie Jane Haig Beattie, MB, lieutenant RAMC

LOVETT DOUST—ATKINSON —On Nov 28, at Oxshott, John William Lovett Doust, MB, to Meriel Atkinson

DEATHS

CANDLER —On Dec 1, John Pycock Candler, MD CAMB, DPH, of Brampton, Hunts

HARVEY —On Dec 2, Alexander William Montgomery Harvey, CB, MB EDIN, major general IMS retd, of Merrow, Guildford

HOWARD —On Dec 2, at Oving, Bucks, Russell John Howard, OBE, MS LOND, FRCS, aged 67

STEWART —On Nov 29, at Beckenham, Frederick William Stewart, MD RUI

TUCKETT —On Nov 28, Ivor Lloyd Tuckett, MD CAMB, of Cowe I W, fellow of University College, London, late fellow of Trinity College, Cambridge, aged 69 t the time of discharge, however, he was posting letters to is wife On each corner of the front of the envelope was ritten her name and address and in the middle were the ords "I love you darling" He was posting these at the rate f six a day, to the embarrassment of his spouse when she ceived them from the postman of a small village

n this case while the emotional balance was apparently estored, there was actually a gross exaggeration of his eeling towards his wife combined with complete absence f that restraint which had previously characterised his ffective behaviour The case illustrates the way in hich the exaggeration of an emotional attitude affects he cognitive ability as expressed in practical judgment wing to a selective restriction on the cognitive side he ailed to appreciate that such a manner of addressing tters conformed neither to his previous standards nor o general usage

During the first few weeks after the return of ordinary onsciousness following a gross confusional state, mental unction though to outward appearance normal remains nstable and easily upset Fatigue and subjection to motional stress both act by bringing about an alteration r restriction of consciousness showing itself in periods f amnesia or fugues inaccessible in the memory of rdinary consciousness, or even in the return of the confusion

Case 6, the soldier who wrote those letters to his wife, illustrates both those factors at work. When discharged, he had to make a long railway journey, and for parts of this journey he has complete amnesia He cannot remember changing trains, though he did so at least twice and with ccess, for he arrived home in average time On two occasions within the first fortnight at home he had a recurrence of his confused condition in which he was disoriented, thought he was in hospital when actually in his own house, and failed to recognise his wife and family These episodes lasted about half an hour, after which ordinary consciousness was restored One of those attacks came on after he had seen an exciting film and the other after a concert They precipitated his transfer to this unit where we were able to observe him

This is only one of several cases where we can be certain that true fugue states can occur in susceptible people ubjected to emotional strain

Alcohol is another potent factor in upsetting mental functioning impaired by severe head injury In the average person it enhances some emotional attitudes at the expense of others and the background of morality and convention tends to be set aside At the same time there is considerable restriction of the cognitive ability With even moderate amounts of alcohol the wrong change is often accepted and the wrong hat donned There is restriction of attention to one aspect only—namely, the shape of the hat and the fact of change being money Here then in the normal person is the beginning of confusion It is not surprising therefore that impairment of mental functions after severe head injury is strikingly exaggerated by even a small amount of alcohol Amnesia may extend over a long period and disorientation is relatively common

The onset of the confusional state may be insidious and show itself in remarkable ways, explicable in terms of change in emotional attitude and restriction of attention such as we have mentioned These may lead to serious involvement of practical judgment

CASE 7 —A woman was admitted to hospital considerably confused and disoriented She had a large basal frontal meningioma and symptoms therefrom had been present for 10 years, attributed to the ever ready diagnosis of change of life The first personality disturbance noted was a shift of affection from her husband to her mother who lived 20 miles away Notwithstanding the distance from home she insisted on visiting her mother daily, thereby seriously neglecting her housework. She stole trifling sums of money from her husband to give as presents to her mother who was in no way in need of them After a year her affection was transferred back to her husband with renewed enthusiasm and he could go nowhere without her Before this change she had been an excellent housekeeper and a stable affectionate wife Interference on the cognitive side was observed when she became muddled in her housekeeping accounts Striking changes developed in her shopping activities When she wanted one quilt she returned home with four, instead of one small kettle she bought two, along with a cauldron costing 17*s* 6*d* On another occasion she bought four blankets all too large for any bed in the house Setting out to buy a suit of underclothing for her husband, she bought two, including long-legged pants of such a size that they overlapped his feet by 6 in She refused to admit her mistake and change them She refused to undress and take a bath, and in spite of a warm summer she wore three pairs of knickers at a time

It is in the realm of practical judgment that the upset due to change in emotional attitude and value together with restriction of the cognitive field is best shown In assessing any practical situation (whether in judging mere size or number, or in the more intricate assessments of the wine connoisseur or the literary critic) where an actual yardstick cannot be at hand, the mental standard is constructed out of a vast amount of previous experience This standard acts as a background which does not appear in consciousness yet determines and makes possible the necessary assessment Everyone of necessity has some such mental yardstick The accuracy and skill with which it is used varies from person to person and from field to field in any one person, and it determines whether he has good practical judgment in that field This intangible yardstick becomes distorted in the presence of exaggerated emotional attitudes and restriction of cognitive attention, and the gross errors in practical judgment follow such distortion

POST-CONCUSSIONAL PERSONALITY CHANGE

The principle of restriction and fixity of cognitive and emotional attitude which we have found important in interpreting confusion in its various forms can also be demonstrated in the personality changes so often found after a severe concussion Two cases of opposing types of temperament illustrate this

CASE 8 —A man, aged 30, received a severe head injury without fracture of the skull He was unconscious for several days and in a state of gross confusion going on to mild confusion for 8 weeks From childhood he had been conventional and timid, afraid of the dark, of water, and later of public opinion As a natural athlete he played football, but avoided positions of danger and games with first-class clubs, giving conventional reasons for this avoidance Timidity in the presence of social superiors was expressed in extreme shyness Because of peculiar family circumstances he felt insecure, though superficially he was friendly and sociable He reached a good average level in clerical work and was conscientious with an eye to promotion On this basis he led a relatively stable existence Six months after his injury his timidity and lack of confidence had become excessive He was extremely embarrassed and ill at ease in the presence of a doctor His speech was evasive and discursive He exhibited nervous mannerisms not previously shown and apologised profusely for imagined social errors He would return on numerous occasions to repeat his apologies He was terrified at the prospect of return to his responsible duties His memory retention was still considerably impaired and he was absent minded Before his head injury the timidity which had been his underlying emotional attitude had been modified and camouflaged by the background of convention (social, educational and athletic) and was scarcely recognisable to the outsider After the injury resulting in basal cerebral atrophy this background ceased to play its modifying part so that timidity, fear and anxiety were strikingly displayed They became fixed and persistent, not merely being called forth by a few situations as before, but characterising all his behaviour

CASE 9 —In this case the picture is reversed After a motor-cycle accident this man was unconscious for 3 days and in a state of confusion for 4 weeks Here the underlying mood had always been one of aggression His upbringing was hard and rigorous His mother died when he was an infant All family arguments were settled by a boxing bout in which he sometimes knocked out his older brothers He was precocious, having his first love affair at 12 At 14 he ran away from home and, giving his age as 18, joined the Army He was ambitious, smart and successful and by 20 had gained considerable promotion On return to civilian life he secured a good appointment On rejoining the Army he received rapid promotion Six months after a severe head injury this man showed no fear whatever, made light of his residual symptoms and wanted to return to work without sick leave He was on a motor cycle as soon as he got out of hospital Prompted by a casual and inoffensive remark he knocked out a colleague He was jovially familiar in his which is perceived The spatial setting therefore acts as a background, without it, true perception of the object would not be possible

Perception of an object is also modified by background in the process of recognition (which incidentally underlies all orientation) Recognition of an object which we have previously seen, either as an individual object or as belonging to a class, involves the presence in some latent way of past experience of that object Such experiences do not necessarily appear in consciousness as memories, but provide a background which plays a part in determining recognition in much the same way as the background of the visual field modifies the nature of the object perceived There are thus at least two kinds of background upon which full appreciation of an object depends—the background of past experience and of present spatial relationships

In the above examples of breakdown of mental activity we find not so much a blurring of figure and background as a severe restriction of the conscious field One of a number of qualities of a single object which are almost essentially related together is singled out to the complete exclusion of the others In a normal person an appreciation of these other qualities would immediately act as corrective clues to the kind of misinterpretation which we find in the confused person

The ability to hold a variety of aspects or qualities together—to appreciate a situation in terms of its characteristic qualities—fluctuates considerably during recovery from confusion When apparently quite well oriented, the patient may revert to perception of partial aspects and to the inadequate orientation which he found satisfactory when those aspects were perceived in isolation There is often a daily fluctuation in orientation So precarious is the patient's grasp of his environment that it is readily upset when the sharp outline and definition of surrounding objects is lost—for example, in the dark In less severe cases of confusion and in various stages of recovery, restriction can still be observed, but not to such an extreme degree

CASE 3—A clerk of 29 sustained a relatively severe concussion, was unconscious for 30 hours and afterwards was acutely confused for 12 hours On admission to hospital, 3 days after his accident, his state was one of puzzlement His orientation was rapidly recovering To all outward appearance ordinary consciousness seemed to have been established, but he had a gross memory retention defect and on the day after admission he failed to recognise the room in which he had been examined the previous day His conversation superficially appeared average though a number of paraphasic errors could be detected Two days after admission this man was sitting talking to visitors, his mother and sister He turned to his mother in conversation for a few seconds, and at the end of it asked "Where is Jeannie ?" though his sister was sitting at his side and had been talking to him a few seconds before While talking to his mother he ceased to be conscious of his sister who formed a background *to* the conversation This incident demonstrates how, as recovery takes place, the influence of the wider field of consciousness returns, in this case he appreciated the full significance of his mother's visit but momentarily ceased to be influenced by his sister's presence The mechanism is similar to that seen in gross confusion but milder in degree It might be interpreted as severe absent mindedness, but his mother judged it to be so unlike his former behaviour as to constitute mental abnormality

CASE 4—In this patient recovery from a severe head injury was almost complete after 8 months and the influence of the background had gradually returned, but mild residual restriction remained which resulted in acts of absent mindedness On 4 occasions this man put salt into his tea instead of sugar He knew there was something the matter with him and was distressed at this performance, not daring to tell his wife in case she should share his fears He even drank the tea in order to hide his mistake

The similarity between ordinary absent-mindedness and confusion is apparent, and the former may be considered as a mild form of the latter The cases described had however never displayed absent-mindedness of such degree before their brain lesions

There are conditions in ordinary human experience in which this restriction of background can be demonstrated An intense interest will temporarily inhibit much of the background Unlike the case of concussional confusion where any part of the may be indiscriminately excluded, here the only of the background which fail to influence are those irrelevant to the main interest The minded professor presents a good example of such restricted field Strong emotion also restricts the of consciousness thereby permitting concentration on relevant details of the situation to which the emotion reaction The irrelevant background of the ment is shut out Love and rage are both popula conceived to be blind We all know the restric perseverative thought of the profoundly depressed p son Restriction of consciousness may go so far in so cases as to produce stupor, or a dream state, consist of a series of images unrelated to any background

EMOTIONAL CHANGES IN THE CONFUSIONAL STATE

Post-concussional confusion also includes much aff tive as well as cognitive disturbance, and there a well-recognised change in mood and emotional at tude In the acute stage of confusion the affect often restricted to a single type of response This called forth by any and every type of stimulus Th is little or no differentiation Such responses especially those of irritability, elation, depression, fe especially when hallucinosis is present, or apathy in the cognitive sphere, so in the emotional life c attitude becomes dominant, even exaggerated, while the other emotional tendencies and responses are abeyance and play no obvious part in modify behaviour

In a normal person, behaviour is the result of a balan between various emotional trends, interests, desir social and moral requirements and restrictions In t confused state the balance is upset, emotional trends isolated and unmodified The inhibitory and restricti influences acquired as a result of social education oft fail to act, giving rise to primitive and excessive respons The restriction of attention to single aspects of situatio reinforces this tendency to the isolated and excessi emotional response Where the environment is n perceived as a whole the response to it will certain appear isolated But the tendency to isolated emotion response also reacts as one might expect on the restricti of the field of attention, just as we have seen that stro emotion in the normal person restricts his attention the object of that emotion Thus a strong desire in t early stage of confusion may determine and restrict t process of reorientation

CASE 5—A man, aged 23, was admitted to hospital in confused state after a severe head injury While still gross confused he thought he was at home and kept calling for wife, who he thought was downstairs When told she was n there he insisted that she must be out shopping, 2 days lat when he appreciated that he was in hospital he shifted orientation to a hospital 5 minutes' walk from his home England and constantly demanded his clothes in order walk home So dominating was the desire to be in or ne his own home that even when his memory and his ability recognise had recovered to an extent which would ha allowed the normal person to have oriented himself perfect well, this man continued to imply in act and in conversati that he was actually in X When challenged he would com promise regarding the difficulty and state that although was in X some people round about him called it a town Scotland or alternatively he said that it might be "classed as in Scotland The disorientation in this case took on delusional status determined by a fixed emotional attitu towards being at home, and cleared up suddenly when h mind was put at rest on receiving a letter from his wife

Even when a patient has apparently recovered from gross post-traumatic confusional state and has adjuste himself satisfactorily to hospital surroundings, emotiona trends may still remain unbalanced and exaggerate and may express themselves in unexpected ways Something more than a superficial talk to such a patien is required to demonstrate any abnormality

CASE 6—A soldier received a severe closed concussiona head injury The period of confusion lasted for 3 weeks, afte which he seemed to recover ordinary consciousness quit rapidly His behaviour conformed to hospital rules and as he was anxious to go home the doctors decided to discharge him

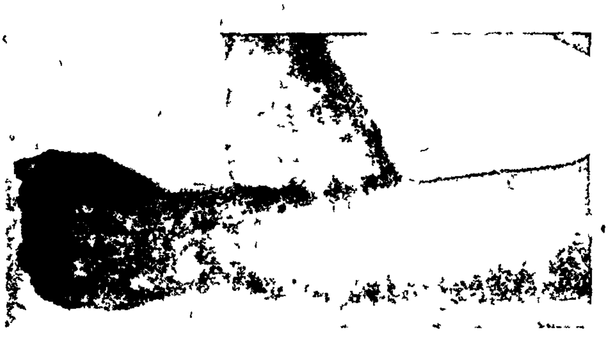

Fig 1—Cutaneous diphtheria multiple lesions secondary to staphylo coccal folliculitis 84 sores were present on the arms from all lesions tested staphylococci and *C diphtheriæ* were obtained

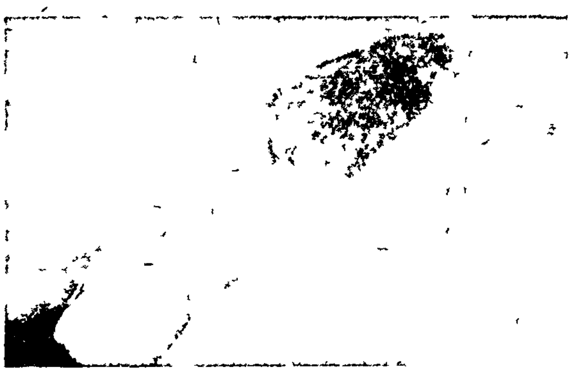

Fig 2—Cutaneous diphtheria secondary to epidermophyton The ulcer *was originally much larger evidence of healing above ulcer*

of skin disease, the commonest associate by far was the desert sore but association was often noted with scratches, insect bites, impetigo, scabies, staphylococcal folliculitis and epidermophyton one case followed typical herpes zoster

Acute cutaneous diphtheria—The acute sore was found both on unbroken skin and at sites of previous trauma The association with diphtheria of nose or throat probably explained why the sore was so often found on unabraded skin of the radial aspect of forearm and dorsum of hand, it was doubtless the result of direct transference through nose-wiping on the part The first clinical sign in such cases was a small blister of pustule centred around a hair follicle, after rupture a flat shallow sore developed with base almost flush with skin and edge composed of skin only—no rolled bluish edge as in the chronic type The base appeared more healthy than in the chronic type and in the absence of mixed infection yielded a pure growth of *Corynebacterium diphtheriæ* In one case aspiration of the pustule before it ruptured gave a similar pure growth Where a pre-existing sore became acutely infected there was no preceding blister but the blackish membrane developed rapidly Size, shape and depth varied with the antecedent lesion

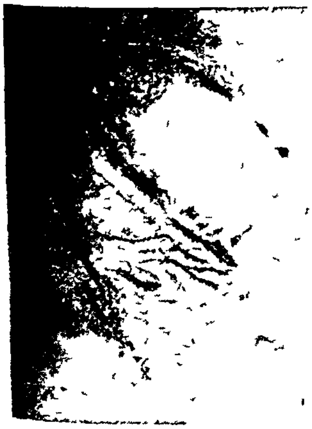

Fig 3—Cutaneous diphtheria chronic ulcer on inner aspect of right thigh with acute contact infection of unabraded skin of scrotum

One case of this type calls for special mention The initial lesion was a mosquito bite of the right upper eyelid This broke down and spread along the lid giving a typical acute sore of the linear type, conjunctivitis was also present Swabs from both sources and also from the nose and throat were positive for *C diphtheriæ* The patient later developed polyneuritis, 80,000 units of diphtheria antitoxin was given in treatment over the first two days of the disease because of extreme systemic disturbance The conjunctivitis was non-membranous

Chronic cutaneous diphtheria—The sores were more commonly seen in their chronic or indolent stage Almost invariably multiple, they were usually found on the elbows, forearms and backs of the hands, the knees, legs and ankles

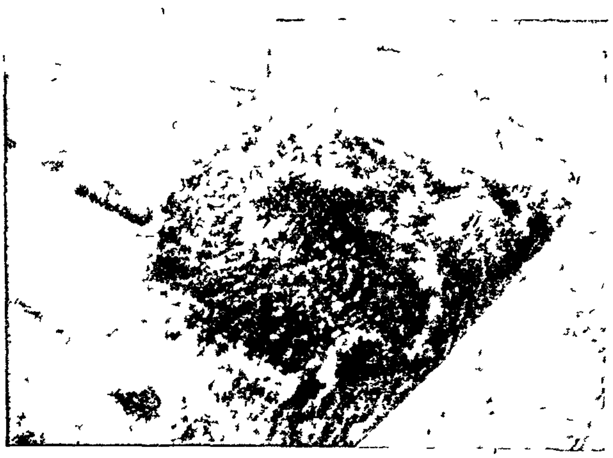

Fig 5—Desert sore on dorsum of left hand staphylococcal infection note irregular outline and absence of depth and rolled raised edge

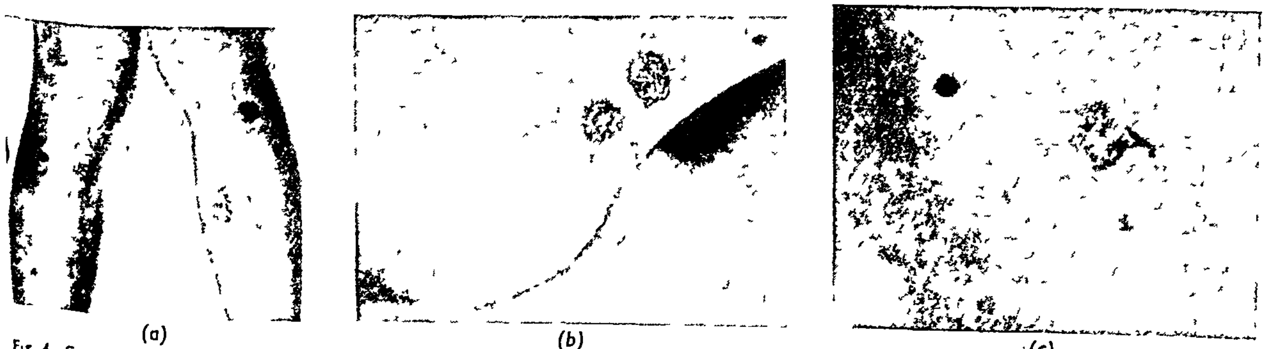
In one patient who had suffered from sores for some two months there were present in a healed or indolent stage 84 lesions on the arms alone (fig 1) Originally small staphylo coccal lesions, the majority yielded positive swabs This case was erroneously described by Manson Bahr (1941) as acute cutaneous diphtheria

The chronic sore was usually circular or oval, occasionally linear in an infected scratch Punched out and clear-cut, it varied in width from a ½ to as much as 2 in



(a) (b) (c)

Fig 4—Cutaneous diphtheria chronic type note regular circular or oval shape punched out appearance raised rolled edge and deep base covered by leather like black membrane (a) and (b) followed insect bites (c) followed traumatic sores on knee and shows the stage of healing

social attitude He treated superior officers as equals and asked a ward sister her age as an opening remark in conversation His farewell salutation to his doctors was "Cheerio, okey doke" The previous underlying emotional attitude was one of aggression and euphoria, but modified by the back ground of Army life and general experience he became a *smart, ambitious, disciplined NCO* He had been entrusted with the responsibility of training soldiers and proper respect and deference towards his superior officers had become automatic After a head injury resulting in basal frontal atrophy, the aggressive euphoric attitude unmasked was dominant and persistent, appearing in inappropriate situations no longer modified by those influences and standards which previously had successfully guided them into useful channels

In these two cases, which are representative of many others, we see what might be called the caricature effect of severe concussional head injury The caricature is obvious, the background of conventional, social and other standards having been cut off, the basic emotional trends are allowed to dominate the field and the future course of the patient's life Air encephalography in both cases and in many similar cases showed basal frontal atrophy

In these cases of the post-concussional syndrome mild residual personality changes are present, interpretable in terms of first, the previous personality pattern in all its ramifications and second, the change in certain of its component emotional attitudes as the direct result of brain damage Supposing however that those two cases exemplifying the end-result of a serious head injury were examined a year later by someone who did not know the course of the post-traumatic psychosis in either case, or the changes in emotional attitude immediately following it, what would be the assessment? The man with the change towards more aggression would be *relatively* easily assessed His present personality picture could be contrasted with his personality before the accident and the difference would almost certainly be regarded as an organic personality change attributable to the brain injury But in the case of the change to excess fear, anxiety and apprehension, the matter is quite different As emotional attitudes, fear and aggression are equivalent, but in the eyes of the general public, and rightly so, there appears something to be gained out of fear and anxiety and the maintenance of that reaction In war-time it may be the avoidance of service which might be dangerous or in peace-time the making of excessive insurance claims It is in this type of case, and they are constantly recurring, where there is nothing *in the symptoms themselves to distinguish the* exaggerated fears and anxieties of the organic personality change from those so often found in the neurotic, that a knowledge of the course of the post-confusional state is essential This cannot be given by the patient himself and is rarely recorded by his medical attendant in sufficient detail to be helpful The importance and the practical value of the study of the post-traumatic psychosis in all its stages are therefore obvious

SUMMARY

Conscious activity comprises many different functions which must all be present before behaviour can be said to be normal They can be knocked out selectively by the various types of brain lesion

The knocking out of any one of those functions resolves itself into a restriction of the background specific to that function It is on the proper activity of this background that the function itself depends

We have studied and analysed the behaviour of people with brain injuries in the light of this principle, looking especially for selective breakdown in various fields, and have found that restriction of conscious activity *to a few aspects only of a* situation and to isolated emotional attitudes are common in such cases, 9 of which are reported here

I wish to acknowledge the wise guidance of Prof D K Henderson and Mr Norman Dott, the directors of this unit My thanks are also due to Brigadier George Riddoch and Air Commodore C P Symonds for advice and criticism, and Dr William McAlister, medical superintendent of this hospital, for access to patients The work has been made possible by the support of the Rockefeller Foundation and the University of Edinburgh

CUTANEOUS DIPHTHERIA IN NORTHERN PALESTINE

J D S CAMERON
MD EDIN, FRCPE
COLONEL RAMC, CONSULTANT PHYSICIAN TO THE SOUTHERN ARMY, INDIA

E G MUIR
MS LOND, FRCS
LIEUT COLONEL RAMC

IN military operations in the Middle East during last war, affections of the skin were a common cause temporary inefficiency among the troops Large numbers of men are again stationed in the same areas, an skin affections are again a major problem One of th more common of these cutaneous affections, and on which caused considerable disability in the last war, i that known as desert sore, veldt sore or Barcoo rot Working in the Sinai Peninsula, Craig (1919) found tha in 67 5% of his cases of such sores the Klebs Loffle bacillus could be isolated The virulence of thes organisms was not determined While not suggestin that all veldt sores are diphtherial in origin, Manson Bahr (1941) points out that in a certain proportion th æetiology must be taken as established Benste (1936) published an account of an outbreak of diphther among British troops on the North-West Frontier I his 46 cases there were 31 of cutaneous diphtheria, th ulcers being situated mainly on the knees hands an arms, *5 cases showed* postdiphtheritic paresis, 3 *of* th cutaneous and 2 of the faucial type Good results wer obtained with antitoxin The whole battalion in whic the outbreak occurred was Schick-tested and those positive (27%) were treated by at least two prophylacti injections Hamburger (1939, 1940) found virulent Klebs-Loffler bacilli in over 3% of the cases of "so calle frontier sore" which he investigated in India

In an outbreak of diphtheria in Northern Palestine reported by Cameron (1942), a large number of cases o cutaneous infection were noted The unit showing the highest incidence of affection was a British Yeomanry one which had been stationed in Northern Palestine since arrival in the Middle East During June-August, 1940, faucial diphtheria broke out in the unit, 12 cases being admitted to No 61 General Hospital A carrier was found and after his isolation and treatment the outbreak seemed to die down Before this outbreak, sores had been noted but they did not seem to be more numerous than in other regiments similarly situated, nor to take longer to respond to the usual local treatments After the faucial diphtheria outbreak the sores continued to be prevalent, but now many of them proved resistant to treatment—indeed seemed to retrogress despite it—and in several deep indolent ulcers developed, 4 of these cases were seen in the same hospital in September, when the unhealthy appearance of the granulating base and the rolled edge suggested the possibility of a diphtheritic infection Swabs and scrapings were therefore taken from the bases of the ulcers after removal of the overlying scabs and these showed the presence of Klebs-Loffler bacilli Other cases of apparently similar skin lesions in the unit were examined and 15 further cases were scraped, yielding 10 positive results Later further cases were admitted from this and other units The condition was found to be prevalent in all parts of Palestine but was especially common in the north

The total number of cases of cutaneous diphtheria from September to December, 1940, was 66 Over this period other types of diphtheria were developing in the same units An analysis of the outbreak showed nasal diphtheria 26, faucial diphtheria 79, cutaneous diphtheria 66 cases, and carriers 78 All cases of cutaneous lesions underwent routine swabbing of nose and throat Of the 66 cases, 42 were unassociated with positive findings elsewhere, while the remaining 24 showed the following lesions faucial diphtheria 8, nasal diphtheria 4, nasal and faucial diphtheria 3, carriers 10 (nose 3, throat 4, both 3)

THE SKIN LESIONS

Cutaneous diphtheria was encountered in two forms, acute and chronic The acute form was always associated with a positive lesion of the throat, or more commonly the nose The chronic form was invariably superimposed on a skin lesion, which might be any form

NATURE OF PARALYSIS IN 12 CASES

Case	Cutaneous lesion	Dose of ADS units	Loss		Paralysis			Circulatory disturbance	Polyneuritis	Muscles affected
			Sensory	Reflex	Palatal	Accommodation	Facial			
1	Legs and fingers (carrier)	24,000	+	+	+	—	—	—	+	R trapezius, serratus, quadriceps, gastrocnemius tibialis ant L quadriceps, gastrocnemius, tibialis ant
2	R. hand acute (nasal diph)	16,000	—	+	+	—	+	+	+	P abdominals, recti and laterals, gastrocnemius L abdominals, recti, ilcopsoas, gastrocnemius, tibialis ant
3	Toe, acute (nasal diph)	40,000	+	+	—	—		—	+	Left sided paralysis with hemiplegic distribution of lower neurone type
4	Feet (carrier)	20,000	—	+	—	—		—	+	Arms free, bilateral quadriceps weakness
5	Legs and arms	20,000	—	—	—	+		—	—	No demonstrable motor weakness except of accommodation
6	Heel	22,000	—	+	—			—	—	Reflex loss with no demonstrable motor weakness
7	Hands and knees	24,000	+	+	—			—	+	Lower limb weakness especially in both quadriceps
8	Arms	20,000	+	+	—			—	—	No demonstrable motor loss, deep reflexes absent on both sides
9	L ankle P leg	20,000	+	+					+	Weakness in left forearm and both lower limbs notably quadriceps
10	Foot (epidermophyton)	32,000	+	+	—			—	+	All muscles of lower limbs with quadriceps + + +
11	Forearm, nose, throat ear	32 000	+	—	—			—	—	Sensory only
12	R. upper eyelid, conjunctivitis (nose and throat diph)	80,000	+	+					+	P gluteus maximus and medius, quadriceps, hamstrings, gastrocnemius, tibialis ant, peroneus longus, toe flexors L As for right with peroneus brevis in addition

common in the Middle East and take considerably longer to heal than at home The climate, excessive exposure of skin to sun, the lack of fresh fruit at certain seasons, the increased tendency to abrasions in certain occupations such as grooming, the difficulty of keeping scratches and bites covered, clean and moist, and the attacks of insects all play their part Consequently any factor which raises the patient's resistance to infection is important Though the suggestion of vitamin-C lack was not supported by intradermal dichlorphenolindophenol tests carried out on a number of the cases and though there were no clinical evidences of other vitamin deficiencies all cases were placed on a diet of high vitamin content To maintain resistance also a high protein intake was given Sodium chloride intake was also high. No vitamin preparations were used other than routine 'Marmite' The chronic sore should be treated in bed with the part immobile as far as possible

In view of the chance of paralysis, diphtheria antitoxin was given to all cases Since no controls were used it cannot be said whether this assisted healing In some cases, however, antitoxin treatment was delayed for some time pending positive diagnosis The general impression in these cases was that healing was more rapid after the injection than before A minimum dose of 20 000 units was given in all instances In view of the high incidence of paralysis it is debatable if the high dosage method of Bie (1940) would not have been justified Probably the long duration of the condition before treatment, with resultant fixation of toxin, would have made even such large doses ineffective Apart from that, antitoxin was not available in such amounts, and in any case such a high incidence of paralysis was never anticipated Antitoxin was given intramuscularly in most cases Manson-Bahr (1941) advises the use of antitoxin (dose 4000 units) in all cases of chronic desert sore and suggests that it should be given subcutaneously around the sore This method was practised in a few cases with multiple sores, but larger doses (20,000 units) were injected No beneficial result was noted from this method; the injected sores did not heal quicker than those, on the same patient, left uninjected Swabs soaked in antitoxin were employed as dressings on some sores in patients with multiple affection. Again no beneficial effect was observed. In these cases the intramuscular injection was also given

Oral sulphanilamide and sulphapyridine were given to some cases without apparent benefit In one case fresh sores appeared while he was under treatment with sulphapyridine Vaccine therapy was given a trial in staphylococcal cases as noted above

The essentials of local treatment are that the sore should be cleaned, extensions to hair follicles with formation of satellite sores should be prevented, and healing should be stimulated and reinfection opposed The sores were commonly in a dried, dirty condition when first seen, with scab or slough covering the base The initial dressings should aim at removing the slough and cleaning the base For this purpose hot fomentations, applications of magnesium sulphate in glycerin, compresses of hypertonic saline or sodium sulphate and hydrogen peroxide were all suitable measures The surrounding hairs were removed and care was taken to prevent the dressings overlapping to allow discharge from the sore to flow over and infect the surrounding skin A dressing cut to fit into the sore is an important point in treatment Once the sore is reasonably clean there are two possible lines of treatment It may be covered with plaster or strapping and left for several days or weeks This has the advantages that the dressings are not frequently pulled off with damage to granulations, and that reinfection is prevented But not all skins will tolerate strapping Where the sore is small, applications of the silver nitrate stick or painting with 10% silver nitrate solution will produce a black slough beneath which healing can take place Both methods were practised with some success In general the best results were obtained by the use of dressings which did not stick to the sore Cod-liver oil dressings under jaconette for three days, followed by the application of scarlet red ointment for a similar period was the treatment most used In the later stages all of the aniline dyes were used and proved efficacious Sulphanilamide and sulphapyridine were used locally in some cases, but the rate of healing of sores so treated showed no improvement on that of control sores in the same patient treated by the above methods

It is unwise to bind oneself to one form of treatment, whatever is done, any large diphtheritic sore is likely to take 3–4 weeks to heal

We wish to thank Colonel D Stewart and his staff, Colonel J Higgins and his staff, especially Lieut -Colonel C R Christian, Major S Cowan and Major R D Mackenzie for their help with the pathology studies, the commanding officers and regimental medical officers of the regiments involved, and Captain E L Manton for the photographs

Walshe, F M R (1918) *Lancet*, ii 232

The edges were hard, raised and rolled, with a pale bluish tinge, and the base was flat and even In many it was covered with a leather-like, dark scab membrane beneath which was unhealthy pus-containing anæmic granulation tissue From time to time this scabbed-over appearance suggested healing but only to bring disillusionment when once again pus appeared beneath the scab Manson-Bahr (1941) records a case where the ulcer had been present for 2 years Enlargement of the regional lymph-nodes was not common in the absence of acute pyogenic infection Many of these sores appeared to originate in insect bites or wounds that had become infected In one case where the patient had an ulcer with a positive smear between the third and fourth toes, a epidermophytic origin seemed probable (fig 2)

Acute and chronic sores may be encountered in the same patient, the acute lesion usually being a contact infection of healthy skin from the chronic This was well illustrated in a patient with multiple chronic sores who developed a positive acute ulcer on the right side of the scrotum exactly opposite a lesion on the right thigh (fig 3) The healed acute sore left little change in the part The chronic sore left a scar which was usually thin, glossy, brownish pigmented and slightly depressed There was no recovery of hair or sweat glands in the scarred part

DIAGNOSIS

An acute diphtheritic infection of the skin may be suspected when blister sores appear on the forearm or hand of patients suffering from active nasal or faucial diphtheria, or where, in such a case, a pre-existing skin lesion in any part of the body becomes obviously exacerbated and develops a yellowish membrane or dark leathery slough The diagnosis can only be proved by finding the *C diphtheriæ* and establishing its virulence

The chronic diphtheritic sore has clinical features which distinguish it from the commoner desert sore It is oval or circular, the edge is raised, rolled and bluish while the base is deep and may show the leathery membrane slough beneath which are pus and unhealthy granulations (fig 4, a, b and c), whereas the desert sore is more irregular in shape, lacks the raised rolled edge, and is shallow, its healthier looking base is covered only by a thin dry light-brown scab of sero-pus which often entangles the surrounding hairs (fig 5) The punched-out appearance of the diphtheritic sore and absence of healing may suggest a syphilitic ulcer but this is easily excluded by the specific tests In areas where it occurs, cutaneous leishmaniasis may strongly resemble the diphtheritic ulcer Examination for the Leishman-Donovan bodies in the fluid removed from around the margin of the ulcer will help to establish the diagnosis

As in the case of the acute sore the diagnosis of the chronic diphtheritic ulcer can only be definitely established by bacteriological findings, though with experience a correct clinical diagnosis can be made in a large proportion of cases Careful preparations are needed before taking a smear The slough membrane must be removed, after which the sore should be treated with a saline dressing, kept moist for at least 24 hours The sore should be freed as far as possible from antiseptic influence The smear should be taken by scraping the surface of the sore and especially under the margins with a spoon or platinum loop, the customary cotton-wool swab being much less likely to give positive results Direct transference to the Loffler medium is desirable One negative finding should not upset a clinical diagnosis In an outpatient, a spirit swab applied for half an hour may be used in place of the saline dressing

BACTERIOLOGY

In the present series no case was diagnosed as diphtheria without bacteriological verification In most of the early smears morphology and fermentation tests were regarded as sufficient evidence Wherever doubt existed growth on Morgan and Marshall tellurite medium was employed for verification Later when sufficient tellurite was available this was a routine By this means a large number of cases with diphtheria-like organisms were excluded from the series, diphtheroids abound in skin sores, and often full bacteriological evidence is necessary before a diagnosis of cutaneous diphtheria can be established

Virulence tests were carried out on 11 cases taken at random from those in hospital, of these, 8 were reported virulent, while 1 of those reported avirulent later veloped polyneuritis In this case no focus of di other than cutaneous was found A second case multiple infection (nose, throat and skin), though ported avirulent, later developed paralysis The vi lence test employed initially was of the intradermal but in later tests intraperitoneal injection was car out with a full autopsy of the animal after death T nose and fauces were repeatedly swabbed in all ca Nasal as well as faucial swabbing should be routine in cases of diphtheria, especially cutaneous.

In a large number of cases a staphylococcal les provided the basis of the diphtheritic sore Th staphylococcal lesions were invariably multiple a included cases of folliculitis, boils and desert sores, staphylococcus being the commonest organism associat with this last In nearly all these cases *Staphylococ aureus* of similar type to the skin infection was found the nose The coagulase test was employed by Major Cowan to establish the virulence of these organis The number of positive results justifies the suggest that a large number of skin infections with staphyloco are of nasal origin and that in such cases a staphylococ vaccine may be of therapeutic value

The diphtheritic infection was thought to have source in the native population This point is discuss elsewhere (Cameron 1942) The horse is exonerated a source of infection, bacteriological examinations horse nasal and salivary swabs, hair, curry-combings, d and wet manure and forage were all negative Cr (1916) ascribed the sores to horses bedded in dr manure, Bensted (1936) reported positive findings in t forage used on the North-West Frontier It is intere ing that much of the forage used in Palestine, includi that tested, was of Indian origin

PROGNOSIS

In all instances the acute sores healed rapidly T chronic sores were remarkably indolent, none heal in under a fortnight after coming under hospital trea ment, over a month was more usual Most of the chronic sores had been under treatment for at least month before admission, one case had had unheal sores for 8 months

Paralyses developed in 12 of the 66 cases 2 were cases of cutaneous diphtheria in carriers, 2 cases we associated with nasal diphtheria with the acute type cutaneous sores, 2 were associated with both nasal a faucial diphtheria, in 5 no focus of diphtheria other tha the skin could be found Of the 66 cases, 42 were u associated with diphtheria elsewhere, of this numb 5 cases developed paralyses Palatal paralysis was foun in one case associated with nasal diphtheria and in patient who was also a carrier, 1 case associated wit nasal infection showed facial paralysis and 1 showe accommodation loss Circulatory failure was prese in 1 case of nasal and acute cutaneous diphtheri Bensted (1936) reported 3 cases of paralysis in 31 cas of cutaneous diphtheria, Walshe (1918) also noted it association with cutaneous lesions Apart from thes records, the association of paralysis with skin diphthe does not appear to have been emphasised The hig percentage incidence makes careful antidiphtheriti treatment necessary, as in the faucial cases, it is to often unavoidably delayed until the toxin has becom firmly fixed Sensory symptoms were manifest in th vast majority of the cases of diphtheria of all types, an are therefore not included in the above analysis Th table gives detailed analysis of the paralysis encountere Points of note are the predominant affection of the low limbs and the remarkable symmetry of the muscle involved In all but one of the cases the paralysis wa a late development after the sores had healed Th longest interval after initial treatment was 149 days

TREATMENT

The acute ulcer required little treatment beyond th of the major causal condition and bland moist dressing to the sore The presence of such a sore did not indicat need for any change in dosage of antidiphtheritic serum the dose of which should be suited to the nasal or fauci lesion

Treatment of the chronic ulcer fell under two heads— general and local Cutaneous lesions are undoubtedly

NATURE OF PARALYSIS IN 12 CASES

Case	Cutaneous lesion	Dose of ADS units	Loss		Paralysis			Circulatory disturbance	Polyneuritis	Muscles affected
			Sensory	Reflex	Palatal	Accommodation	Facial			
1	Legs and fingers (carrier)	24,000	+	+	+	—	—	—	+	R. trapezius serratus quadriceps, gastrocnemius tibialis ant. L quadriceps gastrocnemius, tibialis ant
2	R hand acute (nasal diph)	16,000	—	+	+	—	+	+	+	R abdominals, recti and laterals gastrocnemius L abdominals recti , ileop-oas , gastrocnemius tibialis ant
3	Toe, acute (nasal diph)	40,000	+	+	—	—		—	+	Left sided paralysis with hemiplegic distribution of lower neurone type
4	Feet (carrier)	20 000	—	+	—	—		—	+	Arms free , bilateral quadriceps weakness
5	Legs and arms	20 000	—	—	—	+		—	—	No demonstrable motor weakness except of accommodation
6	Heel	22,000	—	+	—			—	—	Reflex loss with no demonstrable motor weakness
7	Hands and knees	24,000	+	+	—			—	+	Lower limb weakness especially in both quadriceps
8	Arms	20,000	+	+	—			—	—	No demonstrable motor loss , deep reflexes absent on both sides
9	L ankle R leg	20,000	+	+					+	Weakness in left forearm and both lower limbs notably quadriceps
10	Foot (epidermophyton)	32,000	+	+	—			—	+	All muscles of lower limbs with quadriceps + + +
11	Forearm, nose, throat ear	32,000	+	—	—			—	—	Sensory only
12	R. upper eyelid con junctivitis (nose and throat diph)	80 000	+	+					+	R. gluteus maximus and medius quadriceps, hamstrings, gastrocnemius tibialis ant , peroneus longus toe flexors L As for right with peroneus brevis in addition

common in the Middle East and take considerably longer to heal than at home The climate, excessive exposure of skin to sun, the lack of fresh fruit at certain seasons, the increased tendency to abrasions in certain occupations such as grooming, the difficulty of keeping scratches and bites covered, clean and moist and the attacks of insects all play their part Consequently any factor which raises the patient's resistance to infection is important Though the suggestion of vitamin-C lack was not supported by intradermal dichlorphenolindophenol tests carried out on a number of the cases and though there were no clinical evidences of other vitamin deficiencies all cases were placed on a diet of high vitamin content To maintain resistance also a high protein intake was given Sodium chloride intake was also high No vitamin preparations were used other than routine 'Marmite' The chronic sore should be treated in bed with the part immobile as far as possible

In view of the chance of paralysis, diphtheria antitoxin was given to all cases Since no controls were used it cannot be said whether this assisted healing In some cases, however, antitoxin treatment was delayed for some time pending positive diagnosis The general impression in these cases was that healing was more rapid after the injection than before. A minimum dose of 20 000 units was given in all instances In view of the high incidence of paralysis it is debatable if the high dosage method of Bie (1940) would not have been justified Probably the long duration of the condition before treatment, with resultant fixation of toxin, would have made even such large doses ineffective Apart from that, antitoxin was not available in such amounts, and in any case such a high incidence of paralysis was never anticipated Antitoxin was given intramuscularly in most cases Manson-Bahr (1941) advises the use of antitoxin (dose 4000 units) in all cases of chronic desert sore and suggests that it should be given subcutaneously around the sore This method was practised in a few cases with multiple sores, but larger doses (20,000 units) were injected No beneficial result was noted from this method , the injected sores did not heal quicker than those, on the same patient, left uninjected Swabs soaked in antitoxin were employed as dressings on some sores in patients with multiple affection Again no beneficial effect was observed In these cases the intramuscular injection was also given

Oral sulphanilamide and sulphapyridine were given to some cases without apparent benefit In one case fresh sores appeared while he was under treatment with sulphapyridine Vaccine therapy was given a trial in staphylococcal cases, as noted above

The essentials of local treatment are that the sore should be cleaned, extensions to hair follicles with formation of satellite sores should be prevented and healing should be stimulated and reinfection opposed The sores were commonly in a dried, dirty condition when first seen, with scab or slough covering the base The initial dressings should aim at removing the slough and cleaning the base For this purpose hot fomentations, applications of magnesium sulphate in glycerin, compresses of hypertonic saline or sodium sulphate and hydrogen peroxide were all suitable measures The surrounding hairs were removed and care was taken to prevent the dressings overlapping to allow discharge from the sore to flow over and infect the surrounding skin A dressing cut to fit into the sore is an important point in treatment Once the sore is reasonably clean there are two possible lines of treatment It may be covered with plaster or strapping and left for several days or weeks This has the advantages that the dressings are not frequently pulled off with damage to granulations, and that reinfection is prevented But not all skins will tolerate strapping Where the sore is small applications of the silver nitrate stick or painting with 10% silver nitrate solution will produce a black slough beneath which healing can take place Both methods were practised with some success In general the best results were obtained by the use of dressings which did not stick to the sore Cod-liver oil dressings under jaconette for three days, followed by the application of scarlet red ointment for a similar period was the treatment most used In the later stages all of the aniline dyes were used and proved efficacious Sulphanilamide and sulphapyridine were used locally in some cases, but the rate of healing of sores so treated showed no improvement on that of control sores in the same patient treated by the above methods

It is unwise to bind oneself to one form of treatment , whatever is done, any large diphtheritic sore is likely to take 3–4 weeks to heal

We wish to thank Colonel D Stewart and his staff, Colonel J. Higgins and his staff, especially Lieut -Colonel C R Christian, Major S Cowan and Major R D Mackenzie for their help with the pathology studies , the commanding officers and regimental medical officers of the regiments involved , and Captain E L Manton for the photographs

The edges were hard, raised and rolled, with a pale bluish tinge, and the base was flat and even In many it was covered with a leather-like, dark scab membrane beneath which was unhealthy pus-containing anæmic granulation tissue From time to time this scabbed-over appearance suggested healing, but only to bring disillusionment when once again pus appeared beneath the scab Manson-Bahr (1941) records a case where the ulcer had been present for 2 years Enlargement of the regional lymph-nodes was not common in the absence of acute pyogenic infection Many of these sores appeared to originate in insect bites or wounds that had become infected In one case where the patient had an ulcer with a positive smear between the third and fourth toes, a epidermophytic origin seemed probable (fig 2)

Acute and chronic sores may be encountered in the same patient, the acute lesion usually being a contact infection of healthy skin from the chronic This was well illustrated in a patient with multiple chronic sores who developed a positive acute ulcer on the right side of the scrotum exactly opposite a lesion on the right thigh (fig 3) The healed acute sore left little change in the part The chronic sore left a scar which was usually thin, glossy, brownish pigmented and slightly depressed There was no recovery of hair or sweat glands in the scarred part

DIAGNOSIS

An acute diphtheritic infection of the skin may be suspected when blister sores appear on the forearm or hand of patients suffering from active nasal or faucial diphtheria, or where, in such a case, a pre-existing skin lesion in any part of the body becomes obviously exacerbated and develops a yellowish membrane or dark leathery slough The diagnosis can only be proved by finding the *C diphtheria* and establishing its virulence

The chronic diphtheritic sore has clinical features which distinguish it from the commoner desert sore It is oval or circular, the edge is raised, rolled and bluish while the base is deep and may show the leathery membrane slough beneath which are pus and unhealthy granulations (fig 4, a, b and c), whereas the desert sore is more irregular in shape, lacks the raised rolled edge, and is shallow, its healthier looking base is covered only by a thin dry light-brown scab of sero-pus which often entangles the surrounding hairs (fig 5) The punched-out appearance of the diphtheritic sore and absence of healing may suggest a syphilitic ulcer but this is easily excluded by the specific tests In areas where it occurs, cutaneous leishmaniasis may strongly resemble the diphtheritic ulcer Examination for the Leishman-Donovan bodies in the fluid removed from around the margin of the ulcer will help to establish the diagnosis

As in the case of the acute sore the diagnosis of the chronic diphtheritic ulcer can only be definitely established by bacteriological findings, though with experience a correct clinical diagnosis can be made in a large proportion of cases Careful preparations are needed before taking a smear The slough membrane must be removed, after which the sore should be treated with a saline dressing, kept moist for at least 24 hours The sore should be freed as far as possible from antiseptic influence The smear should be taken by scraping the surface of the sore and especially under the margins with a spoon or platinum loop, the customary cotton-wool swab being much less likely to give positive results Direct transference to the Loffler medium is desirable One negative finding should not upset a clinical diagnosis In an outpatient, a spirit swab applied for half an hour may be used in place of the saline dressing

BACTERIOLOGY

In the present series no case was diagnosed as diphtheria without bacteriological verification In most of the early smears morphology and fermentation tests were regarded as sufficient evidence Wherever doubt existed growth on Morgan and Marshall tellurite medium was employed for verification Later when sufficient tellurite was available this was a routine By this means a large number of cases with diphtheria-like organisms were excluded from the series, diphtheroids abound in skin sores, and often full bacteriological evidence is necessary before a diagnosis of cutaneous diphtheria can be established

Virulence tests were carried out on 11 cases taken at random from those in hospital, of these, 8 were reported virulent, while 1 of those reported avirulent later d veloped polyneuritis In this case no focus of diphthe other than cutaneous was found A second case wit multiple infection (nose, throat and skin), though reported avirulent, later developed paralysis The virulence test employed initially was of the intradermal type but in later tests intraperitoneal injection was carried out with a full autopsy of the animal after death The nose and fauces were repeatedly swabbed in all cases Nasal as well as faucial swabbing should be routine in all cases of diphtheria, especially cutaneous

In a large number of cases a staphylococcal lesion provided the basis of the diphtheritic sore These staphylococcal lesions were invariably multiple and included cases of folliculitis, boils and desert sores, the staphylococcus being the commonest organism associated with this last In nearly all these cases *Staphylococcus aureus* of similar type to the skin infection was found in the nose The coagulase test was employed by Major S Cowan to establish the virulence of these organisms The number of positive results justifies the suggestion that a large number of skin infections with staphylococci are of nasal origin and that in such cases a staphylococcal vaccine may be of therapeutic value

The diphtheritic infection was thought to have its source in the native population This point is discussed elsewhere (Cameron 1942) The horse is exonerated as a source of infection, bacteriological examinations of horse nasal and salivary swabs, hair, curry-combings, dry and wet manure and forage were all negative Craig (1916) ascribed the sores to horses bedded in dried manure, Bensted (1936) reported positive findings in the forage used on the North-West Frontier It is interesting that much of the forage used in Palestine, including that tested, was of Indian origin

PROGNOSIS

In all instances the acute sores healed rapidly The chronic sores were remarkably indolent, none healed in under a fortnight after coming under hospital treatment, over a month was more usual Most of these chronic sores had been under treatment for at least a month before admission, one case had had unhealed sores for 8 months

Paralyses developed in 12 of the 66 cases 2 were in cases of cutaneous diphtheria in carriers, 2 cases were associated with nasal diphtheria with the acute type of cutaneous sores, 2 were associated with both nasal and faucial diphtheria, in 5 no focus of diphtheria other than the skin could be found Of the 66 cases, 42 were unassociated with diphtheria elsewhere, of this number 5 cases developed paralyses Palatal paralysis was found in one case associated with nasal diphtheria and in 1 patient who was also a carrier, 1 case associated with nasal infection showed facial paralysis and 1 showed accommodation loss Circulatory failure was present in 1 case of nasal and acute cutaneous diphtheria Bensted (1936) reported 3 cases of paralysis in 31 cases of cutaneous diphtheria, Walshe (1918) also noted it in association with cutaneous lesions Apart from these records, the association of paralysis with skin diphtheria does not appear to have been emphasised The high percentage incidence makes careful antidiphtheritic treatment necessary, as in the faucial cases, it is too often unavoidably delayed until the toxin has become firmly fixed Sensory symptoms were manifest in the vast majority of the cases of diphtheria of all types, and are therefore not included in the above analysis The table gives detailed analysis of the paralysis encountered Points of note are the predominant affection of the lower limbs and the remarkable symmetry of the muscles involved In all but one of the cases the paralysis was a late development after the sores had healed The longest interval after initial treatment was 149 days

TREATMENT

The acute ulcer required little treatment beyond that of the major causal condition and bland moist dressings to the sore The presence of such a sore did not indicate need for any change in dosage of antidiphtheritic serum, the dose of which should be suited to the nasal or faucial lesion

Treatment of the chronic ulcer fell under two heads—general and local Cutaneous lesions are undoubtedly

NATURE OF PARALYSIS IN 12 CASES

Case	Cutaneous lesion	Dose of ADS units	Loss		Paralysis			Circulatory disturbance	Polyneuritis	Muscles affected
			Sensory	Reflex	Palatal	Accommodation	Facial			
1	Legs and fingers (carrier)	24 000	+	+	+	—	—	—	+	R trapezius, serratus, quadriceps, gastrocnemius, tibialis ant L quadriceps, gastrocnemius, tibialis ant
2	R hand, acute (nasal diph)	16,000	—	+	+	—	+	+	+	R abdominals, recti and laterals, gastrocnemius L abdominals, recti , ileopsoas , gastrocnemius , tibialis ant
3	Toe, acute (nasal diph)	40,000	+	+	—	—		—	+	Left sided paralysis with hemiplegic distribution of lower neurone type
4	Feet (carrier)	20,000	—	+	—	—		—	+	Arms free , bilateral quadriceps weakness
5	Legs and arms	20,000	—	—	—	+		—	—	No demonstrable motor weakness except of accommodation
6	Heel	22,000	—	+	—			—	—	Reflex loss with no demonstrable motor weakness
7	Hands and knees	24,000	+	+	—			—	+	Lower limb weakness especially in both quadriceps
8	Arms	20,000	+	+	—			—	—	No demonstrable motor loss , deep reflexes absent on both sides
9	L ankle R leg	20,000	+	+					+	Weakness in left forearm and both lower limbs notably quadriceps
10	Foot (epidermophyton)	32,000	+	+	—			—	+	All muscles of lower limbs with quadriceps + + +
11	Forearm nose, throat, ear	32,000	+	—	—			—	—	Sensory only
12	R. upper eyelid, conjunctivitis (nose and throat diph)	80 000	+	+					+	R. gluteus maximus and medius, quadriceps, hamstrings, gastrocnemius tibialis ant , peroneus longus, toe flexors L As for right with peroneus brevis in addition

common in the Middle East and take considerably longer to heal than at home The climate, excessive exposure of skin to sun, the lack of fresh fruit at certain seasons, the increased tendency to abrasions in certain occupations such as grooming, the difficulty of keeping scratches and bites covered, clean and moist, and the attacks of insects all play their part Consequently any factor which raises the patient's resistance to infection is important Though the suggestion of vitamin-C lack was not supported by intradermal dichlorphenolindophenol tests carried out on a number of the cases and though there were no clinical evidences of other vitamin deficiencies all cases were placed on a diet of high vitamin content To maintain resistance also a high protein intake was given Sodium chloride intake was also high. No vitamin preparations were used other than routine 'Marmite' The chronic sore should be treated in bed with the part immobile as far as possible

In view of the chance of paralysis, diphtheria antitoxin was given to all cases Since no controls were used it cannot be said whether this assisted healing In some cases, however, antitoxin treatment was delayed for some time pending positive diagnosis The general impression in these cases was that healing was more rapid after the injection than before A minimum dose of 20,000 units was given in all instances In view of the high incidence of paralysis it is debatable if the high dosage method of Bie (1940) would not have been justified Probably the long duration of the condition before treatment, with resultant fixation of toxin, would have made even such large doses ineffective Apart from that, antitoxin was not available in such amounts, and in any case such a high incidence of paralysis was never anticipated Antitoxin was given intramuscularly in most cases Manson-Bahr (1941) advises the use of antitoxin (dose 4000 units) in all cases of chronic desert sore and suggests that it should be given subcutaneously around the sore This method was practised in a few cases with multiple sores, but larger doses (20,000 units) were injected No beneficial result was noted from this method , the injected sores did not heal quicker than those, on the same patient, left uninjected Swabs soaked in antitoxin were employed as dressings on some sores in patients with multiple affection Again no beneficial effect was observed In these cases the intramuscular injection was also given

Oral sulphanilamide and sulphapyridine were given to some cases without apparent benefit In one case fresh sores appeared while he was under treatment with sulphapyridine Vaccine therapy was given a trial in staphylococcal cases as noted above

The essentials of local treatment are that the sore should be cleaned, extensions to hair follicles with formation of satellite sores should be prevented, and healing should be stimulated and reinfection opposed The sores were commonly in a dried, dirty condition when first seen, with scab or slough covering the base The initial dressings should aim at removing the slough and cleaning the base For this purpose hot fomentations, applications of magnesium sulphate in glycerin, compresses of hypertonic saline or sodium sulphate and hydrogen peroxide were all suitable measures The surrounding hairs were removed and care was taken to prevent the dressings overlapping to allow discharge from the sore to flow over and infect the surrounding skin A dressing cut to fit into the sore is an important point in treatment Once the sore is reasonably clean there are two possible lines of treatment It may be covered with plaster or strapping and left for several days or weeks This has the advantages that the dressings are not frequently pulled off with damage to granulations, and that reinfection is prevented But not all skins will tolerate strapping Where the sore is small, applications of the silver nitrate stick or painting with 10% silver nitrate solution will produce a black slough beneath which healing can take place Both methods were practised with some success In general the best results were obtained by the use of dressings which did not stick to the sore Cod-liver oil dressings under jaconette for three days, followed by the application of scarlet red ointment for a similar period was the treatment most used In the later stages all of the aniline dyes were used and proved efficacious Sulphanilamide and sulphapyridine were used locally in some cases, but the rate of healing of sores so treated showed no improvement on that of control sores in the same patient treated by the above methods

It is unwise to bind oneself to one form of treatment , whatever is done, any large diphtheritic sore is likely to take 3–4 weeks to heal

We wish to thank Colonel D Stewart and his staff, Colonel J Higgins and his staff, especially Lieut -Colonel C R Christian, Major S Cowan and Major R D Mackenzie for their help with the pathology studies , the commanding officers and regimental medical officers of the regiments involved , and Captain E L Manton for the photographs

CERTAIN bacteria can build up protoplasm from ammonia and carbohydrate, or other related substances of a simple chemical structure , others cannot do this, and require more complex substrates Such substrates which cannot be produced by organisms and which have to be supplied in their environment are termed " growth factors " Once these are present, the organisms grow satisfactorily The biochemical substance at each stage in the synthesis of organismal protoplasm, whether a growth factor or a compound capable of being synthesised, is termed an " essential metabolite," in view of the fact that metabolism cannot proceed without it Any substance capable of interfering with the chemical combination between essential metabolites and their appropriate enzymes will bring about cessation of growth and the ultimate death of the organism Woods (1940) showed that the inhibitory action of sulphanilamide on bacterial growth could be reversed by small quantities of *p*-aminobenzoic acid (here called " paba "), and from consideration of the chemical similarity between these two substances he advanced the hypothesis that paba was an essential metabolite for bacteria, and that sulphanilamide exerted its action by competing with paba for the appropriate enzyme He found that more than 570 mg of sulphanilamide was required to overcome the action of 0 02–0 1 mg of paba Since this is a reversible reaction, relatively large amounts of sulphanilamide can be rendered ineffective by minute quantities of paba

Such an antisulphanilamide action is not confined to paba Woods, investigating in vitro a number of substances chemically related to it, found that benzocaine, procaine, *p*-aminobenzamide and *p*-hydroxylaminobenzoic acid among others were highly potent in this respect He stated that procaine had about the same order of activity as paba itself, but that the effect was not immediate, the delay probably indicating that procaine has no antisulphanilamide action until hydrolysed by the organism

The fact that procaine was found to inhibit the action of sulphanilamide in vitro suggested to us that if a similar action could be demonstrated in vivo this would no doubt have a clinical application in infected cases under sulphanilamide therapy and requiring a local anæsthetic The antisulphonamide action of procaine has also been examined in vitro by Keltch and others (1941) Investigating the antisulphapyridine and antisulphathiazole effect of local anæsthetics derived from paba, they produced evidence in support of Woods's findings They showed in vitro that whereas one molecule of paba counteracted 200–500 molecules of sulphapyridine, one molecule of procaine counteracted 20 molecules That is, paba was 10–25 times as efficient in this respect as procaine The present work was undertaken to determine whether procaine acts in vivo as it does in vitro

METHODS

Experimental animals —Mice were used throughout They varied in weight from 11 5 g to 48 g with an average of 18 8 g Not more than 5 animals were kept in a cage, those injected with hæmolytic streptococci being isolated from controls Where cannibalism occurred, such mice were not included in the experimental data

Test organism —After preliminary trials with various hæmolytic streptococci, the Florence Richards strain was found to be the most suitable The minimum lethal dose of streptococci proved to be practically independent of body-weight and the same dose was therefore used for all weights of mice

Procaine —The appropriate weight of the solid was dissolved in sterile distilled water (All solutions were freshly prepared each day)

Adrenaline (PDCo) —This was diluted with physiological saline in which it remained stable for several hours In water the solution turned pink within an hour or two at temperature

Sulphanilamide —1 g of the dry powder was dissolved 125 c cm of sterile water (maximum solubility) Solution the solid was accelerated by heat, and was maintained keeping the bottle in an incubator at 37° C At temperature crystals formed which blocked the needles

Dosage and mode of inoculation —All doses of adrenaline and sulphanilamide were calculated on a weight basis (mg per g) The mice were reweighed at vals and the doses altered where necessary To avoid infection the hypodermic needles were immersed in bo water after each injection Syringes graduated in 0 01 c cm were used for the smaller doses The needle was inserted int the loose skin of the back parallel to the body surface fc about ¾ in After the appropriate dose had been injectec leakage was prevented by pinching the skin round the needl as it was withdrawn

Toxic and lethal effects did not differ in the various type sizes and age of mice, provided dosage was calculated on body-weight basis The severe toxic signs of procain resembled to a certain extent those of sulphanilamide

Estimation of blood sulphonamide —At the conclusion of th main investigation a number of mice were killed and the bloo sulphonamide estimated by Bratton and Marshall's (1939 method

PRELIMINARY INQUIRY

Before the main investigation could be undertaken, i was necessary to determine the optimum doses of th various drugs used , this was done by giving groups o mice increasing or decreasing doses

Procaine —The maximum non-toxic dose of procain was found to be 0 143 mg /g body-weight (e g , 0 2 c cm 1% procaine for a 20 g mouse) , doses of 0 150 t 0 200 mg /g produced slight excitability, muscula incoordination, rising to severe ataxia and convulsions The maximum non-lethal dose was 0 200 mg /g body weight , doses above this produced ataxia and convulsions proceeding to coma and death in certain cases The minimum lethal dose was 0 525 mg /g body-weight with doses above this all mice died

Adrenaline —The maximum non-toxic dose of adrenaline was found to be 0 0040 mg /g , this is about 300 times the maximum non-toxic dose for man The object of this investigation was to ascertain whether the usua concentration of adrenaline in procaine (1 50,000), as used for local anæsthesia, would of itself have any deleterious effect on the animals In none of the investigations to follow did the dose of adrenaline exceed 0 00126 mg /g body-weight—a dose completely non-toxic to mice

Procaine and adrenaline —Next we studied the effect on mice of a combination of procaine and adrenaline injected subcutaneously A 1% solution (10 mg /c cm) of procaine was used incorporating 1 50,000 of adrenaline The maximum non-toxic dose of procaine with 1/50,000 adrenaline was found to be 0 2 mg /g body-weight (without adrenaline 0 14 mg /g) The maximum non-lethal dose was 0 3 mg /g body-weight The minimum lethal dose was approximately 0 632 mg /g body-weight The addition of adrenaline (1/50,000) to procaine thus allows one to give about half as much again of procaine without incurring any toxic effect

Sulphanilamide —The maximum non-toxic dose of sulphanilamide was 0 5 mg /g body-weight for a first dose and 0 125 mg /g for a four-hourly maintenance dose. No signs of toxicity followed the administration of twice the maintenance dose (0 25 mg /g) night and morning to make up for those not given during the night It is of interest that the maximum non-toxic first dose of 0 5 mg /g body-weight corresponds to 35 g as a first dose for a man of average weight, indicating the remarkable tolerance mice have to the drug

Procaine with Adrenaline and Sulphanilamide —The maximum non-toxic dose of procaine (with adrenaline 1/50,000) for mice under the influence of sulphanilamide was 0 200 mg /g body-weight This did not differ materially from the same dose in mice not injected with sulphanilamide It was found later that this dose was excessive after three days of repeated injections, when it was accordingly reduced to 0 15 mg /g body-weight

Hæmolytic Streptococcus —The first strain of hæmolytic streptococcus (t

It proved unsuitable since the minimum lethal dose suspended in saline was about 900×10^6 organisms The Florence Richards strain was much more satisfactory From a ten-hour horse-muscle digest-broth culture a standard loopful was seeded into 15 c cm of the same medium which was also incubated for ten hours It was then centrifuged decanted and the deposit suspended in saline, and standardised against Brown's opacity tubes The mice were inoculated within an hour of removal of the cultures from the incubator The smallest dose lethal to all mice in 72 hours was 3×10^6 organisms (45 mice were used and the doses ranged from 1×10^5 to 500×10^6 organisms, 5 mice were inoculated with each dose selected) This minimum lethal dose was used in the main investigation, where it was found to kill only 8 of the 10 control mice Subsequently saline was shown to be an unsuitable fluid with which to make suspensions It was found that Locke's solution with 0 5% gelatin added was much more reliable Forty mice were injected with the same streptococcus, the doses ranging from 12×10^6 to 1×10^3 organisms All the mice died with the exception of one of three which received 1×10^3 organisms Locke's solution with 0 5% gelatin is thus superior to saline for ascertaining minimum lethal doses of streptococci (and of other bacteria)

Hæmolytic Streptococci and Sulphanilamide —Before proceeding to the main investigation, it was necessary to ascertain whether the maximum non-toxic dose of sulphanilamide could protect mice inoculated with the minimum lethal dose of hæmolytic streptococci (Richards)

Ten mice each received 3×10^6 hæmolytic streptococci suspended in saline intraperitoneally (1 45 PM) At 2 PM on the first day five were given a first dose of sulphanilamide (1 in 125 solution) equivalent to 0 5 mg /g body-weight, this was followed by doses of 0 125 mg /g at 6 PM and 0 25 mg /g at 10 PM On the second and third days these five mice received doses of 0 25, 0 125, 0 125 and 0 25 mg /g at 10 AM, 2 PM, 6 PM and 10 PM All survived with no toxic manifestations The five controls which received no sulphanilamide all died, in periods of 24, 48, 18, 48 and 35 hours

Thus the maximum non-toxic dose of sulphanilamide, followed by four-hourly doses to maintain an adequate blood concentration of the drug, gives complete protection to mice inoculated intraperitoneally with a minimum lethal dose of hæmolytic streptococci

ANTISULPHANILAMIDE ACTION OF PROCAINE

In this investigation the maximum non-toxic doses of the drugs were administered subcutaneously to mice The loose skin of the back was the site chosen The repeated injections seemed to affect the animals but little, for in only 3 cases in the whole investigation was a subcutaneous abscess found at autopsy, and there is no reason to believe that these small abscesses played a significant part in bringing about the fatal issue (385 mice were used, and over 4100 injections given) When mice became seriously ill, they were placed in separate cages

After three days of two-hourly injections the previously calculated non-toxic dose of procaine (with adrenaline 1/50,000)—0 2 mg /g body-weight—produced slight toxic signs, it was therefore decided that this dose was too large when administered *over a long period and it* was accordingly reduced to 0 15 mg /g body-weight, which proved non-toxic

In the preliminary investigation 3×10^6 hæmolytic streptococci were found to constitute the minimum lethal dose In the present investigation, as the result of an incidental modification of the technique of suspending the organisms, two of the ten control mice which we believed had received a lethal dose survived It is likely that more of the test mice would have died had the dose, as when given to the controls, proved lethal in all cases Nevertheless the findings give a definite if incomplete demonstration of the antisulphanilamide action of procaine in vivo

Procaine was given in 1% solution with 1 in 50,000 adrenaline, the dosage being 0 2 mg /g body weight from 6 PM on the first day till 4 PM on the fourth day, and thereafter 0 15 mg /g All mice except nos 1–4 received these doses Mice 1–4 were given procaine only, the dosage being 0 143 mg /g Mice 1–8 were injected two hourly from 10 AM to 10 PM for 7 days, in all other cases injections were given four-hourly from 10 AM till 10 PM

Sulphanilamide was given in 1/125 solution, the first dose being 0 5 mg /g body-weight Thereafter the mice received 0 25 mg /g at 10 15 AM, 0 125 mg /g at 2 15 PM and 6 15 PM and 0 25 mg /g at 10 15 PM daily

Hæmolytic streptococci (Richards) were given at 5 30 PM on the first day, the dose being 3×10^6, suspended in saline

Results —Of 4 mice inoculated two-hourly with procaine and adrenaline (1 50,000) for 7 days all lived Of 4 mice inoculated with procaine alone for 7 days all lived Of 4 mice inoculated four-hourly with procaine (+ adrenaline) and sulphanilamide for 7 days all lived Of 5 mice inoculated with 3×10^6 hæmolytic streptococci 4 died Of 5 mice inoculated with 3×10^6 hæmolytic streptococci and procaine (+ adrenaline) 4 died Of 5 mice inoculated with 3×10^6 hæmolytic streptococci and sulphanilamide all lived

In addition to procaine the following groups of mice were given 3×10^6 hæmolytic streptococci and four-hourly injections of sulphanilamide

Of 6 mice given repeated large doses of procaine (+ adrenaline) 5 died Of 9 mice given periodic large *doses of procaine 2 died Of 3* mice given repeated small doses of procaine 1 died Of 7 mice given occasional small doses of procaine all lived In all the mice which died, hæmolytic streptococci were isolated from the heart blood and in most cases from the peritoneal cavity as well

Since one of the 3 mice died after receiving continuous doses of 0 06 mg /g body-weight of procaine (+ adrenaline), it became necessary to investigate the effect of yet smaller doses of procaine The infecting dose of hæmolytic streptococci (10^4) was suspended in Locke s solution + 0 5% gelatin Twenty-seven mice were divided into 9 groups, all receiving an injection of hæmolytic streptococci Mice 1–3 received the streptococci only, all the rest received sulphanilamide in dosage as in the previous experiment Mice 7–27 also received decreasing dosages of procaine (+ adrenaline) ranging from 0 06 mg /g to 0 001 mg /g four times daily for 5 days The dose of hæmolytic streptococci used proved lethal while the amount of sulphanilamide administered afforded complete protection to mice Mice which received 0 006–0 001 mg /g body-weight of procaine (+ adrenaline) remained perfectly well Of 9 mice which received 0 06–0 01 mg /g procaine (+ adrenaline) 6 became ill and one died on the third day, in this last mouse, 0 03 mg /g of the procaine inhibited the action of the sulphanilamide Hæmolytic streptococci were isolated from the heart blood and peritoneal fluid at autopsy

CLINICAL APPLICATIONS

From Wood's figures it was calculated that the average amount of procaine used in minor surgery should be sufficient to inhibit all the sulphanilamide in the body, even during intensive treatment It was naturally a disturbing thought that procaine and the other local anæsthetics related to *p*-aminobenzoic acid commonly used, might prove dangerous in cases where sulphonamides are being given in therapy or prophylaxis If it were substantiated that this danger is a real one, then its significance would be appreciated by all who have to perform lumbar punctures in cases of septic meningitis, relieve pleuritic pain, treat war wounds, especially head injuries, deal with abdominal emergencies, suture perineal tears, or carry out a variety of other surgical procedures Again, the pain arising from the intramuscular injection of sulphapyridine is sometimes obviated by the simultaneous injection of procaine, and this would be a questionable procedure if it was shown that by so doing the sulphonamide was rendered inert

The present investigation has shown that procaine has an antisulphanilamide action when injected into mice infected with hæmolytic streptococci This action seemed really significant only in those mice that received the maximum non-toxic dose of procaine at short intervals of 6 such mice 5 died, and it is possible that all might have died had the dose of hæmolytic streptococci been a fully lethal one Unfortunately only 8 of the 10 control mice which were expected to die did so Notwithstanding this, the results are sufficient to indicate that the repeated administration of procaine antagonises the bacteriostatic action of sulphanilamide Where isolated maximum non-toxic doses of procaine were used, this action of the drug was less impressive Of 9 mice so treated only 2 died , these being the only ones which received this dose of procaine with the last injection of sulphanilamide at night It is at present impossible to say whether this observation is of any significance With sporadic small doses there were no casualties However, of 23 mice which received repeated small doses of procaine, ranging from 0 1 mg /g to 0 001 mg /g body-weight, 2 died, indicating that even a fifth of the maximum non-toxic dose when given four-hourly is liable to produce an occasional fatal result

No ill effects were observed in mice from any cumulative action of procaine given as the maximum non-toxic dose at two-hourly intervals It must therefore be concluded that the drug was fully excreted in that time, as the acetylated compound or otherwise, or, if retained in the body, rendered physiologically inert The average blood concentration of free sulphanilamide in the mice used in this investigation was 31 7 mg per 100 c cm , and it is therefore reasonable to suppose that 0 03 mg /g body-weight of procaine can inhibit this amount of sulphanilamide in the body Since in man the optimum blood concentration of sulphanilamide is approximately 6 2 mg per 100 c cm one might expect this amount to be inhibited by 0 006 mg /g body-weight of procaine (i e , 14 c cm of a 3% solution, or 0 42 g for a man weighing 70,000 g) With lower blood concentrations of sulphanilamide, correspondingly smaller amounts of procaine would produce effective inhibition (e g , 14 c cm of a 1% solution for a blood concentration of 2 mg per 100 c cm) Such figures are within the limits of clinical application where sulphanilamide is administered in low dosage, at varying intervals exceeding four hours in the early stages of illness, irregularly, or omitted at night

Before drawing conclusions, it might be well to consider the following points The inhibitory dose of procaine may vary from case to case according to the total amount of sulphonamide and of *p*-aminobenzoic acid (paba) in the body, derived from the infecting organisms and other sources The replacement of sulphanilamide by procaine in the enzyme system is believed to be reversible, depending on the law of mass action or competitive inhibition, as is known to be the case with paba If, however, the enzyme-procaine linkage should prove to be a relatively stable one, then a single effective dose of procaine might interfere with the action of sulphanilamide for many hours

The persistence of the sulphanilamide action of procaine no doubt depends largely on the rate of its excretion, which is governed by many variable factors, such as concentration, dosage, presence or absence of adrenaline, renal and hepatic dysfunction, dehydration and the state of the local circulation and tissues—for example, œdematous or partially devitalised tissues would tend to delay its local removal, thus leaving a depot of procaine from which small quantities would be absorbed over a long period

Since the biochemical changes undergone by procaine in the human body are imperfectly understood, it is uncertain how it exerts its antisulphanilamide action Woods suggested that in vitro it was the hydrolysed product, not procaine itself, which acted in this way Whether this is true in vivo has yet to be shown Paba itself may be one of the derivatives of procaine in vivo, but whatever the active product is it may retain its activity long after all traces of procaine as such have disappeared from the site of injection and from the system

The viability of the bacteria in the presence of sulphanilamide, and the degree of immunity of the host may well decide whether multiplication of the bacteria will occur, and if so its extent, during the stage when procaine is inhibiting the sulphonamide Thus early in the disease, when the viability of the organisms is high and the immunity of the host low procaine may favour growth, while later on, when the sulphonamide has "asthenisised" (Mandelbaum 1941) the bacteria and immunity has had time to develop (Gordonoff and Mundel 1941), the organisms may fail to revive even in the presence of procaine (Using the hæmolytic streptococcus, an in-vivo investigation, as yet unpub failed to substantiate Gordonoff and Mundel's with the pneumococcus)

From the small numbers of mice used in the investigations, and the various factors discussed a we fully appreciate that such quantitative applicat from mice to man as have been attempted, while may be correct, must be regarded as purely tentative

THREE CASES

In the following three hospital cases procaine w given in large single doses during sulphonamide administration

CASE 1 —A miner, aged 39, received in a blast accident numerous lacerations of the face, neck, chest and extremities. Shock was severe and three pints of plasma were administered. Two days after admission to hospital his temperature rose rapidly to 103° F A type 12 hæmolytic streptococcus was isolated from the blood At the commencement of pyrexia he was given 3 g of sulphanilamide and four hours later another 2 g , thereafter he received a maintenance dose of 1 g four hourly Twenty-four hours after the drug was started he complained of pain over the sacrum and right thigh Temperature 102 8° F Examination showed two large, tense hæmatomas These were incised under local procaine anæsthesia in the ward Four incisions were made, about 60 c cm of a 1% solution of procaine being used, and 0 5 g of sulphanilamide powder was introduced into each of the incisions , oral administration of the drug was continued Type 12 hæmolytic streptococcus was cultured from the hæmatomas Twenty eight hours after the operation the temperature was down to normal and there was no further rise Sulphanilamide therapy was continued for three more days The patient recovered completely

CASE 2 —*A man, aged 25, was admitted to hospital suffering* from pneumonia and dry pleurisy with a temperature of 101° F On admission sputum was taken for examination and the infecting organism proved to be a hæmolytic streptococcus Sulphapyridine was given shortly after admission, the dose being 2 g followed by 2 g in two hours, and thereafter 1 g four hourly. Next day the man's general condition had improved and his temperature was 99° F , but severe pain was caused by extensive dry pleurisy and 30 c cm of 3% procaine was infiltrated into the region where friction was audible or pain on respiration experienced Only partial relief resulted, so the injection was repeated 1½ hours later in *the area of residual pain Relief was then complete*, little further discomfort being experienced The temperature settled steadily, being normal in the evening In this case, despite the massive dose of 50 c cm of 3% procaine (1 5 g) given in 1½ hours, there was no evidence of an antisulphonamide effect

CASE 3 —A man, aged 36, was admitted to hospital a week after case 2, with an almost identical clinical picture The infection was pneumococcal, and sulphapyridine was given in similar dosage On the second day there was a normal response to the drug but the pain persisted , 30 c cm of 3% procaine was injected into the affected part of the pleura with almost complete relief In this case the temperature rose three hours later to 99 5°–100 5° F , but thereafter it fell rapidly to normal

In none of these cases was there evidence of a well marked or persistent antisulphonamide action of procaine It must, however, be borne in mind that the local anæsthetic was not given to any of these patients until twenty-four hours after the beginning of sulphonamide therapy One cannot therefore assume that procaine can be given with impunity early in treatment In vitro, larger doses of procaine are required to reverse the action of sulphapyridine (Keltch et al 1941) than sulphanilamide (Woods 1940) It is probable that this also applies in vivo

CONCLUSIONS

Procaine has been shown to have an antisulphanilamide action in vivo

This action becomes particularly obvious where the procaine is administered in repeated large doses early in sulphanilamide therapy (5 out of 6 mice died)

Repeated small doses of procaine produced an occasional fatal result in infected mice receiving large doses of sulphanilamide Such a procedure therefore seems contra-indicated in man

Since the administration of occasional small doses of procaine had no effect on the therapeutic value of sulphanilamide in mice, this procedure can probably be adopted without risk in human cases It is difficult to say what constitutes a harmless dose of procaine, since this will depend on the amount of sulphanilamide in the body, the sulphonamide *p*-aminobenzoic acid ratio, and possibly other factors By comparison with the results obtained in mice in this investigation, 20 c cm of a 3% solution of procaine should prove harmless to a patient with 3 mg per 100 c cm blood concentration of sulphanilamide; but since the sulphonamide *p*-aminobenzoic acid ratio cannot yet be determined this dose might well be cut by half or two-thirds (i e to 7–10 c cm of a 3% solution of procaine or correspondingly greater amounts of a weaker dilution) This amount should prove sufficient in minor surgical operations

The occasional large dose of procaine appears, for the most part, to have no lasting inhibitory action This was observed both in humans and in mice Exceptionally, however, mice died (2 out of 9) after such sporadic doses of procaine It therefore seems unwise to use massive doses of procaine (or a local anæsthetic allied to paba) in cases under sulphonamide treatment, especially early in disease, and more particularly in those cases not receiving intensive treatment Where a large amount of a local anæsthetic is required under these conditions one of the drugs not allied to *p*-aminobenzoic acid should be used

Local anæsthetics allied to *p*-aminobenzoic acid are procaine, 'Larocaine, 'Tutocaine,' 'Butyn' 'Anæsthesin' and 'Orthoform' (methyl-amino-oxy-benzoate)

Local anæsthetics not allied to *p*-aminobenzoic acid are cocaine, tropacocaine, eucaine (benzamine), 'Stovaine' 'Nupercaine' 'Phenocaine,' 'Pantocain' 'Psicaine,' 'Eccaine,' 'Elypin,' 'Apothesine,' 'Diothane,' and 'Metycaine'

This work was carried out with a grant from the Earl of Moray Fund and a Wilkie Research Fellowship We are indebted to Prof T J Mackie and Prof J R Learmonth for their advice and interest in the investigation We further wish to thank Dr E Czszepanski for his assistance and Dr S R Elsdon and Dr S W Challinor for their comments on the biochemical aspects of the subject

New Inventions

A NEW CIRCLE TYPE CARBON-DIOXIDE ABSORBER

With the collaboration of Messrs Coxeter and Son Ltd a circle type absorber in which anæsthetic requirements have been combined with mechanical efficiency has been produced The machine was intended to fit the standard Boyle machine that has been distributed widely in the EMS It slides on two runners fixed under the top shelf of the anæsthetic table frame, and can be pushed under the shelf when not in use (fig 1)

Breathing is restricted as little as possible by using wide bore gas channels and making the patient's breath take a path with few changes of direction Large control drums are used and special glanding arrangements provided to eliminate leakage In the ether vaporiser wicks, which to be effective must be of several thicknesses and which soon restrict breathing have been eliminated The moving parts of the reservoir bag (fig 2), are carefully balanced on ball bearings, and move with the slightest respiratory effort The measured restriction of the circuit is 2 mm water with the ether off and 4 mm with it on

In order that CO_2 should be absorbed as efficiently as possible, the orthodox type of circuit has been replaced by one in which both inspirations and expirations pass through the soda lime thus combining the absorptive efficiency of the to-and-fro type with the practical advantages of the circle type absorber

The ether vaporiser normally used in an absorber circuit has a wick to give sufficient surface of contact of the ether, and to provide a high enough concentration of ether in the mixture The disadvantages of this type are the restriction of breathing caused by the wick and the gradual loss of efficiency due to condensation of water on it Both these disadvantages are overcome in this vaporiser; the wick is dispensed with and instead the gases are deflected by baffles several times on to the surface of the ether Since the gases are brought into the vaporiser at the centre of a concentric nest of baffles, the lowest ether temperature is reached at the centre of the container The temperature drop in the peripheral portions of the ether is minimal and the gases before leaving the vaporiser are in contact with the warmest ether The baffles like the ether pot are made of copper, and act as conductors of heat from the rest of the apparatus to the liquid ether

To make inflation of the lungs easy, whether for control of the respiration or for artificial respiration in emergency, the bag is concertina-shaped It is connected to a lever ending in a knob conveniently placed on the front of the machine Depression of this knob compresses the bag with little effort on the part of the anæsthetist The lever system is balanced on ball bearings The slightest movement of the bag is transmitted to the knob and is thus easily seen The body of the machine is cast in one piece with the drum channels bored in it, to avoid leakage Expiratory and inspiratory valves are fitted to the machine, as well as a nipple through which air can be introduced The soda-lime canister can be quickly removed by swinging aside a large easily loosened sling The gravity valves are made of 'Scolam,' a compressed fibre which allows them to be twice as thick as they would be if made of metal, the possibility of warping is thus diminished, without increase of weight The valves are visible, and are easy and cheap to replace in war-time

Several of my colleagues have given a clinical test to this absorber and I am grateful for their helpful suggestions They have confirmed my opinion that only as a result of collaboration between manufacturers and user can a real advance in the design of anæsthetic apparatus be made

Reviews of Books

Food and Planning

J R MARRACK, MD Camb , professor of chemical pathology in the University of London at the London Hospital London Gollancz Pp 285 15*s*

THIS book encompasses a sound up-to-date statement of the human body's needs in nutrition, a discussion of what people actually eat in different parts of the world, the relation of diet to health, the contact of food-supplies and rationing in the war of 1914–18, the effect of that war upon health, food-planning for present scarcity and planning for a possible future plenty It is thus ambitious in scope , but it succeeds in giving a picture of what is, what could be, and what should be done to supply the world's demands in sound nutrition It might easily serve as a textbook for more forward-looking men of affairs who are determined that our future economy shall not entail one country's starving while another dumps its surplus food into the sea The medical reader will naturally be most interested in the first four chapters which deal in a practical but scientific way with the familiar ground work of nutrition Professor Marrack brings this study up to date and makes it exciting He is no armchair dietitian he gives for example a picture of himself at one point of the book stalking the woods for a " vegetable beef steak " and finding but one, and that woody, in a walk of eight miles Nor do the vast number of trees in the dietetic forest prevent his seeing it for what it is—or might be—with a sound scheme of afforestation The short section on the family's adaptation to war supplies can be heartily commended to any housewife and to any caterer, especially for school canteens and British restaurants, as a practical essay in making the best of a bad job , if our politicians would heed the author's reiterated warning about the needs of the adolescent we should cease to run the risk of a stunted or tuberculous postwar population Social workers will turn to the chapters on what people eat, and health and diet, and will find all the data they need for planning sound national nutrition The last chapter makes a plea for world planning of production and distribution of food The author sees that for any such plan to succeed national self-sufficiency must be given up and the traders' profit motive be taken out of food production While his standpoint is decidedly left of centre, his is no uncritical valuation of socialist doctrine, and he warns us thus in his closing sentence "But if we have not the courage to build a new world with a common purpose, men will again turn from our shortsighted prudence—so reasonable, so respectable, so devoid of hope and inspiration—to creeds that are neither reasonable nor respectable, but do offer some hope and the inspiration of a common purpose " A good, sound, useful and often brilliant book with only one serious flaw it has no index

Intestinal Obstructions

(2nd ed) OWEN H WANGENSTEEN, MD, professor of surgery to the University of Minnesota London Baillière, Tindall and Cox Pp 484 33*s*

THIS is in many respects a new book it has a new title, the format is different, the text is longer, many of the illustrations are original and the arrangement is much improved Wangensteen discusses the effects, diagnosis and therapy of intestinal obstructions, and then turns his attention to special cases of obstruction Accounts of his own experimental work have been abridged and incorporated in Part I, and he has achieved a more even balance between operative and non-operative forms of treatment The indications, the technique, the limitations and the contra-indications to the use of intestinal intubation with the small stomach-tube and the Miller-Abbott tube are described, and pains have been taken to damp over-sanguine ardour in the employment of suction-siphonage, especially when the diagnosis is in doubt The importance of interpreting clinical and X-ray evidences correctly is duly emphasised He does much to further the use of the straight X-ray film of the abdomen to determine whether obstruction is present, complete or incomplete, in the jejuno-ileum or the colon, and if in the small intestine whether in the upper, middle or lower segment Reliable differential criteria are lacking to distinguish between simple and strangulating obstructions , Wangensteen seeks to differentiate them by and radiological methods Surgery is still the of therapy, and he insists that the cases which urgent operation are those of strangulating c and acute obstruction of the colon with much Operative techniques are lucidly described and illustrated He favours end-to-end anastomosis performing bowel resection by the closed or technique, and advises the use of the Petz clamp in expediting intestinal resections and the employment of the ingenious twin resection clamps for closed tomoses, whether these are lateral, side-to side or end-to-side He has made an outstanding contribution the treatment of acute intestinal obstructions in this book.

Pye's Surgical Handicraft

(13th ed) Editor HAMILTON BAILEY, FRCS Bristol. *John Wright and Sons* *Pp 536 25s*

THIS is a second war-time edition The book appears with girded loins and tightened belt, but in spite of the slight reduction in the number of pages the contents have increased through economical arrangement of the type It contains practical advice on the treatment and management of general and special surgical cases, and each section is written by an authority Self-explanatory illustrations support the practical advice given in the text and the medical side of surgery is adequately covered Chapters on diseases which may accompany or complicate surgical cases are written by physicians Most chapters contain something new, and many are by new contributors New chapters deal well with sulphonamide therapy, wound healing and serum administration

Diseases of Women

(9th ed) HARRY STURGEON CROSSEN, MD, FACS , ROBERT JAMES CROSSEN, MD London Henry Kimpton Pp 948 63*s*

THE latest edition of this American classic amply surveys the whole field of modern gynæcology—at one time almost exclusively a surgical specialty but now becoming more and more bound up with endocrinology The authors cover the endocrine aspect with full reference to all important recent work In other respects, too, the book is well balanced and practical, illustrated with good plates and diagrams It remains a standby for all interested in gynæcology

Dental Surgery and Pathology

(8th ed) J F COLYER, KBE, LLD, FRCS, LDS , EVELYN SPRAWSON, DSc, MRCS, LDS London Longmans Green and Co Pp 1067 45*s*

THE additions and revisions in the war-time edition of this good book cover variations in structure and regressive changes in the tooth pulp and the pathology of neoplasms The use of bold headlines, of tabulation and of special type for important points makes the facts memorable Many of the illustrations come from our oldest textbooks, but they are reliable and well chosen The chapter on caries is relevant to the issue of the sweet ration to children and our war-time bread The authors consider there is " abundant clinical evidence to show that the use of sugar is closely connected with the amount of caries," and discuss the decalcifying effects of cereals There is only half the caries in districts with hard water, they find, as in districts with soft water , thus the addition of *calcium carbonate to our* bread may perhaps counterbalance the decalcifying power of the 85% extraction of our wheatmeal bread, plus the effect of the sweet ration The beneficial effect of raw milk, as opposed to heated or pasteurised milk, in preventing dental caries is noted The article on Vincent's ulceration and angina is not very helpful and could be rewritten in the light of present-day knowledge The chapter on fractures of the jaw, though good in its way, is more reminiscent of the last war than this one, perhaps because, as the authors suggest in their preface, the more radical surgical innovations are still in *a state of trial* and experiment, but this does not explain the almost complete omission of bone-grafting. To students this book is almost indispensable , older practitioners of dentistry will look forward to the time when it is further revised and brought into line with the advances in knowledge gained in this war

NEUROTIC CASUALTIES IN THE FIELD

THE appearance of acute neurotic syndromes in the front line of battle may seriously embarrass the medical services, and Major H R LOVE[1] of the Australian Army discusses their prevention, rapid treatment and disposal All agree that the best prophylaxis is by selection of personnel Men of poor intelligence and unstable constitution, revealed by a history of previous breakdown, are not suitable for front-line duties , they should be recognised in time and allocated to less arduous posts Of neurotic casualties in Libya LOVE notes that an unduly large proportion had a definite and easily elicited past history which might have given a clue to their liability to breakdown This aspect of the problem is probably now being tackled much more energetically than hitherto Closely related with the incidence of neurotic casualties is the general morale of the company in which they occur LOVE finds that the rate varies greatly between individual units with fairly equal standards of training and undergoing much the same stress Some weapons of war, such as the dive-bomber and the tank, are more upsetting to morale than others , the better the men are trained in active and passive defence against such weapons the less likely they are to be affected Morale is better and neurotic casualties fewer in advance than in retreat, though in a retreat many neurotics will fall prisoners to the enemy, and so will not swell the medical records of their own side LOVE records that field and AA gunners, who take an aggressive part in the battle at all times, showed a low incidence of neurosis

The clinical picture of acute neurosis in the field includes acute anxiety and fear states, hysterical conversion syndromes and fugues, purposeless running around and screaming " The men with severe fear states," writes LOVE, " between the ubiquity of their fears and the torments of conscience suffered most unenviably It is small wonder that some, if not evacuated from the line, sought relief in a self-inflicted wound or even suicide The truly amazing thing is the manner in which some men, in spite of their mental sufferings, were able by dint of sheer moral courage to carry on and do successful jobs " In the ebb and flow of desert warfare evacuation was none too easy Treatment devolved in the first place on the battalion medical officer, and took on an emergency character The patients had to be quickly knocked out with a full dose of sedative—phenobarbitone, chloral, or failing a better drug, alcohol With some sedation during the day and a full and restful sleep at night, many recovered and could return to duty As in the last war, it has been found that prospects of recovery are much better with rapid treatment near the front line than after evacuation to the rear Both LOVE and CRAIGIE[2] emphasise the need for having physical methods of treatment available on the spot The rationale of these methods was first developed by MIRA[3] in the Spanish Civil War, and their use in a base hospital was elaborated by SARGANT,[4] who pointed out that neurosis in the good soldier arises most readily on the basis of fatigue, exhaustion and loss of weight In battle conditions these cannot of course be prevented , but the battalion medical officer, by seeing that his men do sleep when they have the chance can do a good deal to minimise their effect The first symptom of an oncoming neurosis is often an incapacity to sleep restfully, even when circumstances allow Preconceptions about the " drugging of the troops " should not be allowed to interfere with energetic treatment of this symptom, which may itself start the vicious circle of exhaustion and avoidable neurosis

Apart from the fact that these syndromes arise more readily where there is a constitutional tendency, we know little of their pathogenesis LOVE puts forward the view that the development of the neurosis is a process of conditioning In the constitutionally predisposed the fear reflex is easily and powerfully aroused , in others repetition of the stimulus, with lack of time for extinction, leads to an increasing facilitation and the reflex may be conditioned to wider and wider associations LOVE has likened a third group to the state produced in dogs when inhibitory and excitatory stimuli are very near the animals' threshold of discrimination, and they lapse into a chronically irritable condition when further conditioning becomes impossible , recovery only follows long periods of rest and treatment The suggestion is ingenious and merits further investigation Certainly neurotic states arise after comparatively short experiences of battle and are associated with hypersensitivity to many and not only fear-producing stimuli , these may be refractory even to long periods of treatment and re-education

A STUDY OF AMERICAN MEDICAL POLICY

WHEN the depression in the United States led to heart searchings about the American social system, the medical services of the country came under scrutiny In 1932 the Committee on the Costs of Medical Care reported that there was a tremendous amount of preventable pain and mental anguish, needless deaths, economic inefficiency in medical provision, and social waste The Committee on Economic Security, subsequently appointed, included in its recommendations federal assistance of the maternal and child welfare services and a nation-wide preventive health programme Health insurance was considered but deferred It was particularly at this time and before the Social Security Act was passed in 1935 (which side-stepped health insurance but provided for an expansion of public health work) that the American Medical Association came into the public eye as an opponent of state medicine The medical profession were not unanimous in their view and a Committee of Physicians, which seems to have arisen primarily as an advisory committee of the American Foundation, took up an independent line in favour of governmental intervention in medicine, for which it received wide support The American Medical Association was therefore not only the subject of some public obloquy, but also exposed as not presenting that united front in medical politics which it had tried to foster Those who differed from its policy claimed that it represented merely the views of an active minority of the profession and not of the whole body

It is against this background that Mr GARCEAU's painstaking study[1] of the American Medical Association should be read The association is a federation of 2055 county medical societies with 34 state medical societies interposed between them and the central body Policy filters up from county members' meetings through their representatives at meetings of state houses of delegates, which again send delegates to an annual central meeting in Chicago , and it flows back through the same channels The arrangement is workable and convenient Its efficiency in making the association a mirror of medical opinion must depend on the operation of the machinery It would seem that contests for the position of delegate are deliberately avoided for fear of faction Selection, although requiring formal approval, is in the hands of a few leaders in each area, a system which may provide a good quality of personnel but doubtful representativeness The conduct of business in the central house of delegates is smoothed by the existence of committees of reference which, sitting during the annual meeting, virtually frame its policy These are appointed by the speaker of the house and meet behind closed doors with the officers and permanent officials before presenting their resolutions to the general meeting Their resolutions are nearly always accepted Here there is obvious scope for the play of influence by a small active group of medical politicians and officials in the moulding of policy Similarly the standing committees which handle the affairs of the association throughout the year are nominated by the president for the time being , there appears to be no open contest The association has a large office organisation with experienced officials who actively maintain contact with the periphery in several ways Most important of all is the *Journal* and it seems to be the general view that the editor is the most powerful personality in American medical politics The machinery of the association appears to provide little control over his activities in this field

Mr GARCEAU, after citing the evidence that there is disquiet and distrust of the association in American medical circles, examines as far as possible the signs that it does not express the corporate view of the profession He admits that they are not convincing Whether the vigorous central office has unwisely created medical opinion is an open question After all it is the function of such a body not merely to reflect opinion but also to disseminate information which goes to build it up There have been occasions when relevant facts have been suppressed, as, for instance, the expressed view of the British Medical Association in 1930 in favour of health insurance and its extension to dependants A certain denigration of the British practitioner has no doubt the same political object and its success may be seen even in the writing of such an unbiased and not uncritical student as Mr GARCEAU, who says of the American small-town doctor, "He may be a good deal more than the English panel practitioner and yet a good deal less than a man up to date in his field" That the misconception underlying this statement is among American doctors is a repercussion of the paign of the American Medical Association any movement toward what it describes as medicine Mr GARCEAU suggests that intra in medical politics may lead to loss of prestige medicine in its day-to-day occupations An open in the profession may lead to questioning of its bility in technical matters The association, thinks, has recruited able men, allowed them to good incomes, but failed to hold them so respons that they will keep the group out of trouble " mechanism is not a guarantee of a healthy society and a healthy government The group must learn to deal with an active political minority within its membership, not to accept them passively or go on a campaign to scalp them all There is a strong need for more politicians, surely not for less" His chief proposal, that a party system within the association might be developed, hardly seems a satisfactory remedy There is more to be said for dropping the façade of internal unanimity by opening the electoral door to its representative positions and administrative offices

BISMUTH IN SYPHILIS

ALTHOUGH undoubtedly rapid in antisyphilitic action arsphenamine soon proved its inability to deal alone with syphilis infection in its entirety In the early years this inability was compensated by the retention of mercury as a supporting agent, but from 1921 onwards that veteran was gradually superseded by bismuth For many years now it has been traditional in European circles to treat the early lesions of syphilis with both these remedies, either at the same sitting or within the same week, and since this combined therapy seemed satisfactory it was natural that efforts were made to produce a stable chemical union of these two agents which would combine not only their structure but also their antisyphilitic effect Such a combination of bismuth with a pentavalent arsenical was launched in 1925 by LEVADITI under the name of 'Bistovol' (bismuth stovarsol), which contained 15% of arsenic and 41% of bismuth Some degree of antisyphilitic effect was reported for this compound but its use never became widespread and evidently the union had failed to achieve the desired summation of the efficacy of the two components In the meantime there have been trials of other combinations, such as bismuth arsanilate and bismuth tryparsamide, but reports on their success or otherwise have been scanty

Another of these compounds, 'Bismarsen,' synthetised by RAIZISS in 1925, has been used over a period of fourteen years by BEERMAN, SHAFFER and LIVINGOOD[1] of Philadelphia This preparation, defined as bismuth arsphenamine sulphonate, containing 13% of arsenic and 24% of bismuth, is a welding of the bismuth element into a trivalent arsenical—the arsphenamine base—in contrast to the inclusion of the less active pentavalent arsenical radicle exhibited in bistovol It does not seem to be the hoped for fully effective combination, for BEERMAN and his co-workers found it appreciably less successful than bismuth and arsphenamine administered separately The healing effect on early syphilitic lesions was good but slow and the relapse-rate about 12% Systemic reactions were met with after only 0 5% of injections, and the compound appears to have been well tolerated by sufferers from late syphilitic affections, particularly cardiovascular lesions, which showed some encouraging improvement Among the 823 patients there were 5 examples of arsphenamine dermatitis and 5 of purpura hæmorrhagica There were no deaths, and no examples of hepatitis or jaundice, though this complication has been reported occasionally by others using bismarsen The long-term results are of special interest Of 71 patients treated for early syphilis and observed for periods ranging from six months to fourteen years, serological relapse occurred alone in 4 and in conjunction with the reappearance of infectious surface lesions in 4 others One or more examinations of the cerebrospinal fluid were made during the period of observation in 48 of these 71, and only 6 showed any abnormality, about half of the patients with fixed serological reactions showed a later reversal to a negative Although healing of the tertiary osseous and cutaneous lesions in middle-aged and elderly patients takes place more slowly, it seems that bismarsen may be used with advantage in these patients especially when they do not tolerate other organic arsenical compounds well

Postarsphenamine jaundice, under the title of 'Salvarsan' jaundice, was a formidable interrupter of treatment and a cause of ill health and some deaths during the last war, and there has lately been a recurrence of the unsatisfying discussions on the rôle played by suspected factors other than arsphenamine in its production[2] The old ground of alcohol, diet, vitamins, intercurrent infection and so on has been explored again without bringing to light any very illuminating facts, but although instances of jaundice following bismuth treatment alone are occasionally encountered the possibility of bismuth being a factor seems to have been neglected KULCHAR and REYNOLDS[3] report that of the 1032 male prisoners in the United States prison at San Quentin receiving treatment for syphilis between 1936 and 1942, 144 (13 9%) became jaundiced, and in 121 (10 3%) of these jaundice appeared while bismuth was being given The treatment system consisted of neoarsphenamine or 'Mapharsen' in courses of ten weekly injections in alternation with courses of twenty weekly injections of sodium iodobismuthite There was no epidemic of catarrhal jaundice among the prisoners during the period of this study and the endemic rate was low—0 1% in 1941 Among the 121 cases of jaundice during bismuth treatment, 4 became jaundiced during the first course of bismuth, and previous arsenical therapy could be excluded The remaining 117 received arsenicals in some form before the course of bismuth during which the hepatitis occurred Jaundice began within four weeks of the last injection of an arsenical in 34 cases and in these the arsenic is considered as a possible factor Jaundice was not evident until the fourth to the eighth week of bismuth therapy in 83 cases and in the ninth week or later in 56 cases It was thought that the time intervening since the last injection of an arsenical in these cases made it unlikely that the jaundice was entirely due to previous arsenical therapy Many syphilologists, however, would not accept this short time limit as permitting the exclusion of arsenic as a possible factor, for examples of postarsphenamine jaundice may be met with up to four or five months after the last arsenical injection Although the evidence presented by KULCHAR and REYNOLDS for ascribing a major rôle to bismuth in these cases is not unequivocal, their report serves as a reminder that bismuth puts an additional load on the liver, and might, like arsenic, prepare the ground for virus infection

---

Annotations

ALLERGY IN CHILDHOOD

SIR ARTHUR HURST, speaking at the section of disease in children of the Royal Society of Medicine on Nov 27, glanced at fashions in asthma cures during the past century the nasal cauterisation of Francis, the early skin tests of Chandler Walker of Boston, the allergen-free chambers of Van Leeuwen, and modern methods of desensitisation The most potent cause of an attack, he finds, is expectation, and he thinks it better to inject a small dose of adrenaline to abort an attack in its early stages rather than to keep a patient on an abnormal diet and in a special environment Despite this discouraging picture, Dr George Bray believes in having a try Attacks of asthma in early childhood, he considers, all have an allergic basis, but as the attacks recur they begin to be precipitated by non allergic factors such as excitement, emotion, exertion, and fatigue He recognises three types a hereditary type with a family history of allergy, a variant of this which he calls the eczema-prurigo asthma type, and a tissue damage type, associated with severe colds, bronchitis and pneumonia In a third of the hereditary cases there is a history of infantile facial eczema, and in three-quarters of them the asthma sets in before the third year The breast-fed child often becomes sensitive to such things as milk and gruel, eggs and egg concentrates, egg milk chocolate, milk drinks containing eggs, and cotton seed which is a component of 'Lactagol' Allergic mothers should avoid such foods during pregnancy and lactation, he suggests On weaning the child may become allergic to cow's milk or some cereal such as wheat, oats or barley If cow's milk is responsible it should be boiled for 5 minutes and after the scum has been removed should be acidified These processes have already been carried out on 'Allergilac', other substitutes for fresh cow's milk are evaporated or condensed milk, goat's milk or synthetic milk made from soya bean flour The eczema-prurigo-asthma syndrome commonly appears during the first six months of life with itching, vesicular and papular eruptions and lichenification from scratching, the flexures *being particularly affected*, in the second or third year bronchitis, asthmatic and hay-fever attacks may be added to the picture, and all are persistent up to puberty The skin is ichthyotic in a fifth of the children Sensitising agents vary with the age of the child, in infantile eczema up to the age of 9 months for each 20 food reactions (usually to egg, milk or wheat) there is only 1 inhalant, between 9 months and 2 years the proportions are 20 food reactions to 8 *inhalants*, over 2, in cases of flexural eczema, the proportions are 20 food reactions (usually fish, pig, nuts or vegetables) to 24 inhalant reactions (usually to animal hairs, pollen, or feathers), and in cases of asthma, vasomotor rhinitis and hay-fever, for 20 food there are 100 inhalant reactions It is among this last group that some of the largest reactions are seen to pollens and horsehair In the tissue damage type of allergy, asthmatic attacks are often restricted to the winter months and a respiratory infection sometimes associated with measles or whooping-cough provokes the first attack In this type of allergy, fibrotic changes may be seen in radiograms of the lungs, but in the other two types they are rare. Sensitivity is usually to inhalants—feathers or down, among which the child spends his time when ill. He may occasionally also become sensitive to foods such as milk, gruel, barley and albumin water. Dr Bray believes in restricting the diet of the allergic child and suggested a basic diet which excludes cow's milk in its natural state, pig and pig products, shellfish, nuts, chocolate, strawberries, apples, bananas, beans, peas, tomatoes, potatoes, cabbage, and celery. The child's bedroom should be airy and free from dust, without hair or feathers in the bedding. He recommends only two medicines: min 10–20 of hydrochloric acid in water before meals if there is hypochlorhydria, and ephedrine linctus at bedtime every night for several months. If the child is sensitive to dust or pollen, desensitising injections often give good results. In the light of long experience Mr James Crooks suggested that while nasal surgery was not curative of allergic conditions any septic focus should be dealt with on general lines; and Dr F A Knott remarked that sensitisation with bacteria had never been demonstrated in any cases he had seen.

NINE LIVES OF STATUS LYMPHATICUS

AFTER a careful pathological and statistical analysis of 600 odd cases of either sudden death in apparently healthy people or death in people of 15 years or over who had an apparently glandular thymus, Young and Turnbull[1] in 1931 reported that they found no evidence that so-called status thymo lymphaticus had any existence as a pathological entity, and a leader in our own columns[2] seemed justified in announcing, without sorrow, the end of the status. A few years later Cohen[3] agreed that "the term status lymphaticus used in the coroner's court is a meaningless expression." Yet three years ago Taylor[4] reported on 14 cases in which the only explanation of death was in his view a general excess of lymphoid tissue, making it clear that it was this general excess rather than enlargement of the thymus which should be looked upon as predisposing to death from trivial causes. And now Millar and Ross[5] have satisfied themselves that one of the other characteristics of the lymphatic state—aortic hypoplasia—is significantly associated with accidental death. In a series of autopsies in which they measured the aortic circumference at a fixed level they first eliminated aortas with well marked atheroma, and those from obese, emaciated or œdematous patients, leaving 300 measurements for analysis, 26 being from patients dying as a result of accident. By applying multiple regression corrections, variations for height, age, weight and sex were eliminated, and it then appeared that the mean aortic circumference in the accident cases was 1 48 mm less than in non accident cases. From this Millar and Ross argue that aortic hypoplasia is connected, probably indirectly, with liability to accident, and even imply a connexion with "accident proneness." The argument is fallacious. We are told no details of the accidents, whether they were in air raid, factory or on the road. The existence of accident proneness is well established from close observation of the precise nature of industrial accidents; without detailed study of circumstances it would not be right to connect 26 accidental deaths with accident proneness as Newbold[6] understands it. Technical improvement in post mortem work is, day by day, finding causes for deaths which only 10 years ago would have been regarded as mysterious, and in the heyday of status lymphaticus would have been assigned thereto. Careful interpretations of data have elucidated deaths from functional causes like vagal inhibition, carotid and reflex,[7] and careful technique has established the unsuspected frequency of air embolism,[8] ammo embolism,[9] allergic death[10] and the like, all missed wi case. There may well exist, as Campbell[11] puts it, " condition of such lowered resistance and hypersuscept bility that the patient so affected is in danger of sudd death from trivial causes"; one feature of this conditi may be a type of aorta with narrowing and hypoplas of its wall, but the connexion between the two has to be convincingly established. And there is alwa *a cause of death awaiting detection.*

THE BRITISH STANDARD HÆMOGLOBINOMETE

THE British Standards Institution, which has alread done good work in drawing up standard specifications f the various pipettes used in hæmatology, has no tackled the hæmoglobinometer itself. British standa 1079 1942 gives the specifications for constructing standard Haldane hæmoglobinometer.[12] Both the tu into which the blood is put for dilution and that contai ing the standard solution of carboxyhæmoglobin a described and the colour of this standard solution defined. The standard solution is so prepared that, before, 100 per cent corresponds to 13 8 g hæmoglob per 100 c cm blood. A regular source of annoyance the past has been that hæmoglobinometer tubes were n interchangeable—even if from the same manufacture the blood tube had to be carefully checked against t comparator tube to ensure that the distance between t 20% and 100% marks corresponded; only too often did not. Adoption of the standard will stop this commo source of error. Since the manufacturers are represente on this organisation, it should follow that all hæmoglobi ometers will now conform to standard. *It is up to t* purchasers to insist that their hæmoglobinomet tubes should be marked "B S 1079," and to refuse a others. This will help to make hæmoglobin estimation truly comparable. The next task for the institution *to define standards for the next most popular hæm* globinometer—the Sahli.

STAPHYLOCOCCAL SCARLET FEVER

SINCE the early twenties, when the ætiological relation ship of the hæmolytic streptococcus to scarlet fever wa established by the Dicks and Dochez, it has been common experience among clinicians who use th throat swab as an adjunct to diagnosis *to find that* small proportion of clinically typical cases fail to yiel *Streptococcus pyogenes* from nose, throat or open infecte lesion. There are several possible explanations for th apparent anomaly—the swabs may have been inexpertl *taken (but repeat swabbings have proved negative),* th infection may be deep seated and inaccessible, th infecting strain of streptococcus may be a non hæmolyt variant such as Colebrook and his co workers[13] recovere from septic wounds, or the streptococcus may fail t grow or fail to produce hæmolysis under aerobic con ditions. Now that anaerobic culture is more widel practised it is not uncommon to find strains of *Strep pyogenes* which grow only, or much more profusel anaerobically than aerobically on primary culture, an there is point in the practice adopted in some laboratorie of inoculating the swab as a "pour plate" which ensure growth in the medium as well as on it and encourage both the growth and hæmolysin *production* of strains which are aerobically shy. With these obstacles overcome, it is probably a fair estimate to say that 98% of scarlet fever is due to an erythrogenic streptococcus. From time to time, however, evidence is adduced in favour of the staphylococcus as etiological agent, and this evidence is reviewed by Aranow and Wood[14] along with the report of a case of staphylococcal scarlet fever This was a girl, aged 13, who developed a scarlatinal syndrome as a complication of acute osteomyelitis with septicæmia (54 colonies of *Staphylococcus aureus* per c cm of blood) The rash was typical in character and distribution and was followed by general desquamation, there was a "raspberry" tongue, and the fever and toxæmia apparently responded dramatically to scarlatinal antitoxin A high antistreptolysin titre was found in convalescence A filtrate of the infecting staphylococcus grown in broth gave positive Dick tests in a dilution of 100, that is, the organism was poorly toxigenic compared with the scarlatinal streptococci, but its toxin was specifically neutralised by streptococcus antitoxin, and its activity was destroyed by heat at 61° C for one hour Other workers have isolated erythrogenic staphylococci from the throat or other sites in cases of non streptococcal scarlet fever, and Satake[15] reproduced the scarlatinal syndrome by injection of such a staphylococcal filtrate The erythrogenic toxin is apparently unrelated to the more common staphylococcal hæmolysin and leucocidin This evidence in favour of the staphylococcus as a rare cause of scarlet fever is perhaps in line with the broadening concept regarding erythrogenic toxins Instead of a single streptococcus and a single toxin, antigenically identical whatever its source, we now know that many different serological types (and possibly Lancefield groups other than A) of the hæmolytic streptococcus can produce erythrogenic toxin, and that streptococcal toxins of differing antigenicity are capable of producing scarlet fever

SEEING IS BELIEVING

THE pathologist is not always right even if, speaking broadly, he has a good pull over the clinician One of the happiest hours in the Swiss medical student's week was the Saturday midday when that brilliant pathologist Ernst Hedinger put the dead "meat" on the table and challenged physicians and surgeons to justify their in vivo impressions The pathologist however does not often get the chance of checking up a long series of clinical diagnoses with the post-mortem findings For nearly 30 years it has been the custom at the Royal Adelaide Hospital for the house surgeon to fill in a request card when he obtains permission for autopsy On this card is written the clinical diagnosis which it is presumed would have been placed on the death certificate had there been no autopsy Prof J B Cleland has analysed[16] 2500 of these entries and finds that the clinical diagnosis was right (or reasonably so) in 67 8%, partly right in 12 4%, wrong in 14 6%, whilst in the remaining 5 2% no diagnosis was made or the nature of the lesion remained obscure even after autopsy It should be borne in mind, he says, that in a large general hospital many patients are admitted in extremis, or die before a proper examination can be made In 89 cases at least of the 362 in which the clinical diagnosis proved wrong death had occurred on the day of admission to hospital or on the following day Some of the larger groups of diseases are analysed in detail Thus it was noted that in malignant disease the number of cases missed was nearly but not quite counterbalanced by those in which it was suspected but not present In cardiac infarction a correct diagnosis was made in 80%, the instances in which this condition was present but not diagnosed were counterbalanced by those in which it was diagnosed but not present Cerebral hæmorrhage and cerebral softening were usually correctly diagnosed, but more cases of softening were diagnosed as hæmorrhage than the other way round Of wrong diagnoses, failure to recognise pneumococcal peritonitis stands out in the list as most important, most pathologists would agree that this is often missed Of the rest, general peritonitis due to perforation, bronchopneumonia as a cause of coma, chronic fibrosing pulmonary tuberculosis with pleural effusion simulating heart disease, are diagnostic snares which routine autopsy is apt to reveal On the whole Professor Cleland's figures bear out the adage that the common things are commonest

NORTHERN ROSES

HIP COLLECTING has become a scientific pursuit In an address to the Pharmaceutical Society on Dec 10, Mr R Melville, PhD, botanist to the Royal Botanic Gardens, Kew, recalled that we learned of the vitamin-C content of hips mainly through Russian researches In a survey of British roses made last year with Pyke[1] he found that the vitamin-C values of the hips of different species ranged from 1260 mg per 100 g in *Rosa mollis* to 80 mg in *R arvensis* In addition to *R mollis*, the species with the highest content were *R sherardi*, *R coriifolia* and *R afzeliana*, and these four only form an appreciable part of the rose population north of the Lake District, which explains why Scottish hips have given a much better yield of the vitamin than those gathered in the south These species also happen to be among the earliest to ripen, but there is no true correlation between vitamin-C content of the hips and early ripening, since some of those species which ripen first have a poor content of the vitamin The real correlation is probably with the length of day in the period just before ripening, for this fits in with the latitudinal correlation noted by both English and Russian workers To avoid loss of vitamin the hips should be processed with as little delay as possible, but if they must be stored the temperature should be well below freezing point Melville has found that cool storage at temperatures round about freezing point is not satisfactory, there are appreciable losses of vitamin during the first three weeks, and though a fairly steady level is maintained during the second month the content drops again rapidly in the third month The initial losses were greatest in over-ripe hips, and it is thus important, he pointed out, to stop the collection of hips before they begin to show signs of softening To travel well and withstand delays they should be full red but quite hard

HISTORIAN OF THE IMS

Colonel D G Crawford, who died at Ealing on Dec 9 at the age of 85, has left his own memorial Born at Chinsura in 1857, his father being a member of the Bengal civil service, he qualified at Edinburgh in 1881 and entered the IMS the same year He retired in 1911, rejoining for five further years on hospital ships during the late war His *History of the Indian Medical Service* (1600–1913), published in 1914, throws many curious sidelights on old-time Anglo-Indian life, but its main purpose was to record the evolution of a homogeneous service from the small beginnings of the 17th century True to British precedent, early mistakes were made good and utilised to achieve order and success In Emerson's words, which Crawford was wont to quote, they builded better than they knew Crawford's history ranks with the best of the many regimental histories of the British Army, and in 1930 he completed his *Roll of the Indian Medical Service* How he found time in the short human span to collect his knowledge and compile these rolls is easy to ask but can only be answered by those aware of the self-sacrificing devotion entailed, and Crawford found time also to be generous, for he contributed many notes about the Army Medical Service which have yet to see the light in an addition to Johnston's roll

NUTRITION AND ECONOMIC POSITION OF CEYLON

LUCIUS NICHOLLS
M D CAMB
DIRECTOR

ANANDA NIMALASURIA
M B LOND, M R C P
MEDICAL OFFICER

BACTERIOLOGICAL INSTITUTE, COLOMBO

THE first nutritional surveys in Ceylon were carried out in prisons and other institutions where clinical signs of malnutrition were found to be prevalent In the latter part of 1933 and the early months of 1934 similar surveys were done in numerous schools throughout Ceylon In these early surveys most attention was paid to two signs of dietary deficiency follicular hyperkeratosis (phrynoderma) and "sore mouth" The former follows vitamin-A deficiency, and the latter, which includes angular stomatitis and eroded tongue, follows a deficiency of riboflavin Both were prevalent among the primary-school children—phrynoderma in 29% and sore mouth in 8 3% [1]

During 1934 and 1935 a severe epidemic of malaria occupied the attention of health officers of the medical department, but from 1936 onwards increasing attention was paid to malnutrition Qualitative dietary surveys showed that the diets of the poorer classes consisted of parboiled rice and very small amounts of pulses, fish, and vegetables, too highly laced with chillies and other potent currystuffs

Lectures on nutrition with special reference to local conditions were given to the medical officers, and with the establishment of a division of nutrition in the Medical Department lectures were given to all sanitary assistants and health nurses Stress was laid on the need for more variety in the diets of the labouring classes and an increase in the consumption of pulses, vegetables (especially green leaves) and fruits, and above all on the need for more milk for children Public lectures were given and posters displayed A pamphlet detailing the faults of labourers' diets and the methods of improving these was circulated to every estate superintendent in Ceylon The subject was taken up in the State Council and large sums of money were voted for a midday meal in schools attended by the more indigent children There was little doubt that the country was becoming alive to the importance of nutrition, and this was reflected by a great increase of leafy vegetables and other foodstuffs in the urban and rural markets of Ceylon

About two-thirds of the rice and much of the dried fish and pulses consumed in Ceylon are imported The production of money crops in preference to food crops may lead to greater prosperity in times of peace but gives rise to a serious hazard in war Since the outbreak of war the efforts to increase the internal production of foodstuffs have been redoubled and the government has spent much money in bringing this about Large surveys were carried out in the latter part of 1938 and the beginning of 1939, and again in 1941 and 1942, the results are compared with those found in 1933 in table I

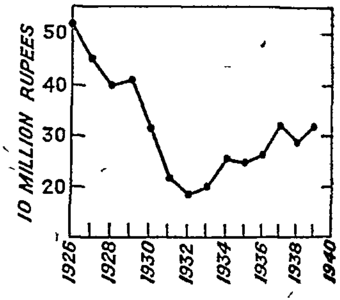
TABLE I—INCIDENCE OF CLINICAL SIGNS

Year	Children examined	Phrynoderma	Sore mouth	Bitot's spots
		Cases and per cent		
1933–34	3792	1101 (29 0)	314 (8 3)	
1938–39	5184	205 (4 0)	676 (13 4)	91 (1 8)
1941	3420	18 (0 5)	246 (7 2)	30 (0 9)
1942	3823	11 (0 3)	78 (2 0)	30 (0 8)

We have carried out parts of the surveys independently since 1934 and the results were consistent

The economic position in Ceylon must be considered in reference to this astonishing decrease in two signs of malnutrition The years 1925 to 1927 were boom years and the years 1928 and 1929, though there was a little falling off, were prosperous, but in 1930 there were signs of a slump and in 1931–33 Ceylon was suffering with rest of the world from a severe economic d The figure shows this well The principal exports tea, rubber and coconuts, and these, having reached total value of 509 million rupees in 1926, fell to a value 173 million rupees in 1932 The exports of a cc cannot fall in value to 35% of the previous total w all classes of the population being affected in one or another

Imports fell more or less pari passu with the exp but the labouring classes are mainly concerned with imports of foodstuffs It is necessary to consider the in the amounts of foodstuffs which were imported and not their value, because the latter fell during the slump. In 1929 the amounts of rice and dried fish imported into Ceylon were 10 62 and 0 339 million cwt and these figures fell to an average of 9 63 and 0 307 during the years 1931 to 1933 Amounts gradually rose, and in the last prewar year (1938) had reached 11 13 and 0 380 million cwt The fall in the amounts of the imports of foodstuffs had been more than 10% when allowance is made for the growth of the population, with the return of better times these imports increased by about 15% over the slump years



Exports from Ceylon, 1926-39

The value of foodstuffs fell considerably more than the rate of wages Rice averaged 27½ rupee cents per measure for the first 5 years (1926–30), and from 1932 to 1938 it has averaged just under 16 rupee cents The price of dhal averaged 21 rupee cents during 1926–30, and afterwards was steady at 13 cents to 1938, and there were similar declines in the values of all other foodstuffs The rate of wages fell from 10 to 20%, but there was an even greater fall in the value of foodstuffs, being for the more widely used comestibles such as rice, dhal and fish 30–50% These falls are shown in table II

TABLE II—PRICES OF PRINCIPAL FOODSTUFFS AND WAGES

Year	Rice cents per measure	Dhal cents per measure	Dried fish cents per pound	Wages * cents per day
1926–30	27½	21	29	52
1931	21	13	30	52
1932–38	16	13	19	45

* Wages vary in different districts

DISCUSSION

Phrynoderma and sore mouth have been found to be valuable indices of the prevalence of malnutrition among the school-children in Ceylon The considerable fall in recent years in the prevalence of these signs has followed activities by the Medical Department to make people mindful of nutrition, a midday meal to the more indigent children, efforts by the Agricultural Department to encourage a far greater production of foodstuffs within the country, and the appearance of increased amounts of more approved types of vegetables in the market Equally, however, the fall has followed improved economic conditions, and, as the first surveys were made just after the depression, the prevalence of signs of malnutrition then found was probably due to the depression

It is impossible to decide how much of the improvement in nutrition of children has been due to direct action by various departments and how much has followed improved economic conditions, but it seems likely that economic improvement has played the greater part This does not imply that the medical efforts are not of great importance

The war has come nearer to Ceylon, and strict rationing has been introduced The state of nutrition of the labouring classes will be watched by repeated inspections of school-children for phrynoderma, sore mouth and

---

1 Nicholls, L *Ind med Gaz* 1933, 68, 681, 1934 69, 241

r signs Signs of dietary deficiency which have been found valuable in nutritional surveys in the tropics will probably also be useful in assessing the state of nutrition of the people of the distressed countries of Europe

GENERAL MEDICAL COUNCIL

WINTER SESSION, NOV 24–28, 1942

(Continued from p 708)

The Premedical Examination

Dr R J **Brocklehurst** presented a draft memo from the subcommittee appointed to prepare evidence for the departmental committee of the Board of Education, presided over by Sir Cyril Norwood The first question asked had been "What are the defects in the present school curriculum from the point of view of equipment for the medical profession?" Replies from licensing and other bodies had emphasised the poor standard of English of entrants to medical schools, most of them had stressed the undesirableness of premature specialisation in the premedical subjects when at school It was suggested that the reason for this was the desire to take the 1st MB from school, and to get scholarships in its subjects The proposal made was that the general education of the future medical students should differ in no way from that of their fellows, they should receive a broad education, including the general principles of physical and biological science Attention should also be called to the dearth of scholarships for medical students, which made competition keener

The second question was on the preclinical studies, and whether the 1st MB should be taken from school or later The replies showed a preponderance in favour of taking this examination and its course from a medical school, either wholly or after preliminary studies at school The committee realised that some schools were better equipped than others to provide this course, and that it would not be fair to exclude the possibility of taking the examination from school, provided there was an assurance that the general education had reached a sufficiently high level before specialisation began It was, however, preferable that at least a part of the 1st MB course should be taken at a medical school This would ensure uniformity, it was not the custom of the council to insist on uniformity in matters of this kind, but those who supported this view felt that if pupils came from a large number of different schools there was no guarantee that the standard attained would be substantially the same More important as a reason was that the teaching of 1st MB subjects should have a definite medical trend, in schools future medical students were in a minority and the teachers were not in touch with medical needs In a medical school the teachers of physics, chemistry and biology were in close touch with teachers of the professional subjects

Sir **Farquhar Buzzard** thought that one of the chief causes of early specialisation was the scholarship and the competition between schools He urged that scholarships should be awarded for merit, and should bear no relation to the future career of the student The choice of medicine could be made after the award In no other way would the right kind of medical student be selected

The **President** pointed out that most of the educational scholarships available throughout the country were earmarked for other subjects, and very few were available to medical students

Time pressing, the report was accepted as a draft of evidence to be given by representatives of the council, subject to verbal amendment on the lines suggested in the discussion

The Pharmacopœia

Dr **David Campbell**, chairman of the Pharmacopœia Committee, said that in the last few days it had been possible to get a promise of enough paper to publish some copies of the BP, and he hoped they would be available in 1943 A sixth addendum was likely to be soon needed Research in the BP laboratory had included work on sulphonamide ointments, standards for kaolin administration, and a method of assessing particle size. The multiplicity of names for the same substance had caused difficulty to medical men and pharmacists, and the BP Commission had published lists of approved names and a memo indicating the lines upon which names would be selected in the future

Further Charges against Medical Practitioners

IMPROPER CERTIFICATION NOT PROVED

In the case of *Michael Murphy*, MC, registered as of 2, Undercliffe Lane, Bradford, MB *Glasg* (1913), the charge was that he issued two certificates, on Dec 22 and Dec 29, 1941, stating that Mr Wilkinson, a constable in the City of London Police War Reserve, was suffering from gastro-enteritis and unable to follow his occupation, that he did not make any or any proper professional inquiries before writing the certificates, and in fact Mr Wilkinson acted as a chorister at St Paul's Cathedral on ten occasions between Dec 23 and Jan 4 The complainants were the City of London Police

Respondent was accompanied by Mr Oswald Hempson, solicitor who said that his client had no memory at all of this case It was quite impossible for a doctor to control the activities of his patients or to check a statement about diarrhœa The patient's duties involved an 8-hour stretch of duty which would be impossible for one suffering from enteritis Mr Hempson protested that a fuller inquiry into the facts of the case ought to have been made by the police and the council before submitting his client to the ignominy, inconvenience and expense of answering a charge He read a statutory declaration from Mr Wilkinson, affirming that he had suffered from diarrhœa at the time and that he had not told the doctor (who was a locum tenens in the practice) that he was a chorister He was fit to go to half an hour's choir-practice after spending the morning in bed, but not to do police duties He had subsequently been diagnosed as subacute appendicitis He had been dismissed from the police force for attending choir-practice while under medical certificate, and was now on night work which made it impossible for him to attend before the council

The council did not find the charges proved

ERASURE IN RESPONDENT'S ABSENCE

In the case of *William Lyle Paterson*, MC, registered as of 140, W Granton Road, Edinburgh, LRCPE (1916), the charge was that he issued a certificate on April 23 1942, stating that the condition of Mrs Henderson, wife of L/Bdr Henderson, was such that her husband should if possible be stationed near home, that he wrote to the military authorities on the same day confirming this certificate, saying, "Mrs Henderson is in a rather pitiful state of nerves mostly due to air-raids She is not, in my opinion, capable of looking after her children I most strongly recommend that her husband be stationed near at home", that he had not seen or examined Mrs Henderson for at least a year before April 23, 1942, and did not examine her before writing the certificate and letter A further charge was that when, on Oct 7, 1942, Dr Paterson visited Andrew Munro of Edinburgh in his professional capacity he was so far under the influence of drink as to be incapable of properly carrying out his professional duties towards him

Respondent was not present, nor was he represented Mr Winterbotham called his managing clerk, Mr Jones, who described how he had gone to Edinburgh to see the doctor and try to persuade him to attend, or give a proper answer to the charges Dr Paterson had said he could not afford to attend or to instruct a legal representative He admitted giving the certificate, saying that he had been asked by Henderson to keep an eye on his wife and to give a certificate if asked He had seen her in the street and twice at her house, and had formed his opinion of her He had shown her the certificate, and had been paid 2*s* 6*d* for the visit and 1*s* 6*d* for the certificate His records had been lost in a recent removal

Mr Winterbotham read a statutory declaration from Mrs Henderson, stating that, though Dr Paterson had formerly attended her, she had not seen him for over a year, and had never seen the certificate There had been no talk of her going to hospital in April of this year, though there had been earlier

In respect of the second charge, Dr Paterson wrote denying it completely and asking why no complaint in respect of it had been made to him He was not, he said, a heavy drinker, but drank only mild ale Mr Winterbotham said that the relatives of Andrew Monro declared that the doctor was drunk and dazed and did not know if the patient's leg was broken or not Monro's sister had sent for an ambulance after the doctor left and the patient had gone to hospital, but returned home the same night Sergeant Norman Gordon of the Edinburgh City Police testified that he had received a report on this case at 4 45 PM and had called to see the doctor about 5 10 PM There was nobody in, but he had traced the doctor to a public-house nearby and had come to the conclusion that he was then drunk , he was unsteady, his voice thick and his coat stained Witness had not smelt his breath The doctor denied ever having been to the Monro's house, but witness had later collected from the house a prescription for powders and ointment that the doctor had left there A statutory declaration from a constable supported the sergeant's evidence Mr Jones, recalled, said that the doctor had no recollection of this incident When witness had called at 1 45 (the surgery hours being 2–3) he had found a notice on the door " Back in half an hour " He also had traced the doctor to a public-house He was sober, but in a very degenerate state—dirty, unshaven, without collar or tie The surgery was very untidy The doctor looked " soaked " and was vague and " doped " He said he had cared for nothing since the death of his wife two years ago and the news recently that his son of 15 was missing, presumed drowned

The council found the charges proved, and the Registrar was directed to erase from the Medical Register the name of William Lyle Paterson

Five names were, after deliberation in camera, restored to the Medical Register *George Holman*, *Joseph Stenson Hooker*, *Benjamin David Lang*, *Andrew Thornton* and *John Mackay Young*

MEDICINE AND THE LAW

Inquest dispels Criticism of Hospital

NEITHER for the first time nor for the last a coroner's inquest has performed the useful function of ventilating the complaints of relatives against the treatment of the deceased in hospital Criticism was offered by the widow and brother The widow said that her husband was transferred to the Radcliffe Infirmary from the Hospital for Diseases of the Heart at Maids Morton She telephoned to the infirmary, asking if she could see the patient on the following Monday She was told that she could, but, when she arrived, she found that an operation had been performed without notice to herself and that her husband was dead The brother complained that the hospital authorities, knowing that the widow was on her way, should have awaited her arrival before operating , that the condition of the patient's heart made operation inadvisable , and that the patient was not in a fit state to sign the form agreeing to the operation In view of these complaints the coroner adjourned his inquiry so as to be able to obtain the fullest information , he furnished the relatives with copies of the medical evidence so that it could be considered by them in consultation with the family doctor Medical witnesses explained that the patient was admitted suffering from retention of urine He was treated for this condition and tests were made An anæsthetic was thought advisable Except that the patient suffered from a bad heart, there was no reason to fear danger Dr. Oliver Lloyd, assistant pathologist, stated that, although there was evidence that the patient would almost certainly have died in the near future, it was probable that the anæsthetisation slightly accelerated death The operation was necessary for his immediate relief , there was no indication of any want of due care or skill , death was due to acute pharyngitis, bronchopneumonia and congestion of the heart

When the inquest was resumed after the adjournment, there was further medical evidence that the anæsthetic was justified as the only chance of prolonging life Dr F G Hobson, honorary physician at the infirmary, said that he found the deceased was not a good subject for a general anæsthetic owing to the cardiac condition , he so reported, but there were cases when the risk had to be taken The relatives withdrew their criticism, the widow saying that she now knew that it was not so much an operation in the true sense of the word as an examination The brother said they now thought that the action at the infirmary was right in the circumstances The jury, finding a verdict in accordance with the medical evidence, exonerated the medical staff and exp satisfaction with the care taken Thus once agai coroner's inquest justifies itself Those who still d its abolition would have to invent something similar for its replacement

In England Now

A Running Commentary by Peripatetic Correspond

CAIRO at the moment is one of the most ama cities in the world It is packed to overflowing the most extraordinary medley of people, and th only about 100 miles from the front line life goe as though the war did not exist Indeed, but for swarms of troops in the streets and the 'planes overh it would be quite possible to forget the war for an or two As the place is one of the holiest of Mu cities it has not been bombed, presumably becaus as well not to offend the whole of the Muslim w without getting some advantage out of it The be its mosques rival those of Stamboul and the med quarter of the city delighted me , imagine a dense work of narrow winding streets, each one given up special craft and called after it, filled with men squat in the front of their open shops hard at it The in the Street of the Coppersmiths is deafening , dirt, flies, people everywhere I like my squalor t alive

One thing I had not expected, because I'd n thought about it, and that was traces of the Napole occupation, but there are many , cannon balls bu in the wall of Hassan's mosque, the fort built on Mokattam Hills, and better still, Shepheard's built on site of the house he first lived in which he took the A fearsome place Shepheard's, packed with rese which caused the Germans much apprehension du the advance on Alexandria, so they said on their wire whereas the defences of Egypt gave them no anx whatever ! You can realise how painful is the lot civilian living among these reserves One day I waiting for a lift when a major dashed up , with bo head, hat in hand, I silently motioned him in f " Go ahead " he shouted cheerily and as we shot up bellowed " speak English ? " It was clear that meant well, he wanted to give the poor dog a leg I looked at him for some seconds with the defac interest of an entomologist looking at a new specie louse and then I said gently, " Sir, every comp gleaming fibre of me is English except 50% which Irish, and I speak the language with elegance, viva and precision " The major, who was quite mottled this time, spluttered, " My dear chap so e to make mistakes nowadays chaps at sea Nordic features beards Irish blood r self ! " We parted friends, but I left Shephea within the hour and plunged into the Suburra of Ca where I felt much more at my ease

After some days in Cairo I went up the river to Luxor and Karnak Until you have seen the Nile can't realise how it *is* Egypt We grow up on a s of " It flows through old hushed Egypt and its sa Like some grave mighty thought threading a drea picture of it, and leave it at that, but it's only when y have followed the river for some hundreds of miles a watched the Arabian escarpment to the east, the Liby to the west, with glimpses of desert beyond on bo sides, that you understand how the 16 million Egypti exist It is strangely beautiful country , the ri was falling, but there was still much water about in t irrigation channels and every now and then a great la dotted with clusters of mudbrick houses surround by date palms Every possible square inch of the riv basin is cultivated and the country was green with you corn and millet Flocks of egrets, ibis and bee eate and camels doing all sorts of work everywhere (nas supercilious beasts , I hate them)

Luxor and Karnak are too overwhelming for a sho visit Unfortunately it wasn't " the season " (not th seasons of that sort still exist in Egypt) so the pla was deserted My dragoman, a dear one-eyed Ara Moustafa Khalil, used to start the day at 8 AM a we went round in a battered old arabieh drawn b two horses which were just skin and bone By noo the shade temperature was 98–99° F but dry heat, and everyone made for what shade there was In the Valley of the Kings, which is on the edge of the Libyan Desert and is itself desert, it was impossible to do anything after noon What fighting must be like in such conditions I shudder to think. Hieroglyphs are much lovelier to look at than I had thought they would be In the finest tombs their colour and outline are incredibly well preserved, and as I had expected some of them closely resemble their Chinese counterparts

An exhausting train-journey took me back to Cairo the day after Ramadan had ended The carriage was packed and everyone was friendly and willing to write Arabic, which pleased me and taught me the alphabet The number of one-eyed people in Egypt must be a record for any country, I began to think half of them had had trachoma The dust is very trying to us, but *doesn't seem to* affect them in the least The number of pock-marked faces in adults is also strikingly high, but presumably they are vaccinating better now for the young are unscathed

I was tired of ships and the sea so I flew on from Cairo Flying is much too good to be true, you peer down at this magnificent panorama which is unrolled beneath you, you have a vivid picture in your head of a coast-line, and yet *you're furious when the expected bump appears* and is in fact Mt Carmel I must fly more, it still seems much too unreal to me For following a campaign you cannot do better than fly I sweated through the desert with the French to El Arish, I stormed Jaffa and massacred everyone in sight I gloated over the fruit of Nablus and I was held at Acre by Sidney Smith I was so excited by Acre that I shouted “ There's Acre ” and was promptly crushed by a general sitting next to me Then the spike of Cyprus loomed up on the horizon, pale, pale yellow, the island seemed to leap up at us, and ten minutes later I landed completely deaf The doctor and a sanitary inspector called Homer met me ! “ Was Zeno really born here ? ” I said, and they rocked with laughter

Twenty-five miles by road up to Nicosia through arid desolate looking country, into the Kyrenian range far away to our north Cypresses and olives again, no crops yet, though we grow much of our own barley Nicosia I reached as dusk was falling, a little walled city in the middle of a plain It looked very lovely with its minarets outlined against the fading lights Cyprus seems to be full of walled cities and superbly preserved medieval castles Think of an emergency hospital in one of the finest castles in Europe—vaulted rooms with stone slabbed floors and walls many feet thick I don't know much about medicine here yet, but I have seen a little schistosomiasis and leishmaniasis and Cooley's anæmia

* * *

Before the war I went as surgeon on a cadet ship to the Antipodes The skylights of the boys' washing place were just outside my cabin and their voices and the sound of splashing waters came clamouring up to me In this ablutionary parliament what I admired most, apart from the rounded beauty of the oaths was the downrightness of the judgments “ Young Watson ” was “ an utter squirt,” “ a septic blister, and ”—never or—“ a dirty piece of toe fug,” or the Mate was “ the fore end, the after end, the bight of ”, apparently they had been reading about dysentery All this condimented with the usual body-fluid adjective and the onomatopœic participle, rather in the same way as the Greeks used *μεν* and *δε* In war, which in many other ways too is a return to adolescence, we class people as either black or white, drawing from the pent-up wisdom of the ages which taught that those who are not with us must be deemed against us, for a neutral in one's rear might be lethal That is why the Darlan business has rankled in the public mind Most of us can still hear the Prime Minister's voice lashing his name like a bullock whip Whatever the logic of the matter, I doubt whether any leaders can afford to ignore the instincts of their people

* * *

By an extraordinary coincidence I have exchanged a view, from my hut, of Mt Hecla in Iceland for that of Mt Hecla in the Outer Hebrides Hecla is Norse for hood, and in Iceland refers to the cloud-cap Before I came home I had yet another trip into the interior—by car from Reykjavik to visit Gullfoss and Geysir At that time Geysir was erupting punctually at 6 PM every day, so we arranged to visit Gullfoss, in a neighbouring valley, first, and reach Geysir in time for its display of a column of boiling water 200 ft high Gullfoss is a magnificent double waterfall in an almost right-angled bend in the glacier-fed Hvita (White River). One can stand opposite the falls at such a height that the surface of the river above the falls is a little lower than one s eyes That part of the river is in open country with low banks, and the water seems to be rushing straight at one But it suddenly falls over a high ledge running diagonally across the river and seethes and rages over tumbled rocks until it meets another, very deep, cliff running across the river on the opposite diagonal to the first Here the whole river plunges into a dark chasm, whose bottom cannot be seen, and an immense cloud of spray is thrown up to produce a glorious rainbow in sunshine Below the falls the river runs in a deep and narrow gorge When we reached Geysir we found that a party had arrived about 4 PM, and produced artificially a premature eruption by casting 150 lb of common household soap (no coupons required) into the monster's maw So we had to content ourselves with throwing two bars of soap *into a smaller edition, called Smith, which soon began to* boil and bubble, becoming troubled like the pool of Siloam, and finally shot up a column of hot water about 8 ft high Besides these two there are scores of other hot-springs close by, and new ones open up, while old ones close down A famous one, called Strokhur, is now dead and looks like an underground railway tunnel diving vertically There is also a hotel, with gymnasium, hot swimming-pool and glasshouses warmed by hot-springs We drove thence to Thingvellir, past roadside pools mantled with thousands of minute golden water-buttercups and past a horrific lava-field and imported reindeer It was one of those days on which the sun did not shine boldly but filtered through light cloud, allowing the colour tones of Icelandic landscape to appear at their best The roads were a bright deep red, being gritted with baked lava The fields were tawny and various shades of green The lower slopes of the mountains were covered with grey, green or golden mosses The far-away mountain tops stood out deep purple or dark blue, slashed here and there by pure white glaciers Nowhere have I seen such marvellous colours in landscape Nevertheless give me the trees and woods of England, where the scenery is warm and friendly, not naked and hostile

* * *

Just as the 9 o'clock news began I was summoned by telephone to see the young wife of Eves, our idiotic grocer, who was reported to be terribly bad with hæmorrhage I leapt upon my trusty bicycle and arrived to find a very healthy-looking young woman with a pulse-rate of 70 who was having a rather profuse period No, she hadn't missed any, but when she was 16 she lost a lot and the doctor had kept her in bed for three months “ But that was hæmorrhage, doctor This isn't hæmorrhage, is it ? ” “ *Of course,* it is,” I explained “ Hæmorrhage only means bleeding If you cut your finger you get hæmorrhage ” “ Yes, but this isn't from the womb ” “ Yes, of course it's from the womb I'll give you an injection for it ” “ Oh, no, I won't have an injection, thank you ” “ Why not ? ” “ Well, I've never had an injection before ” There didn't seem to be any answer to that one so I tried another tack “ Why did you send for me ? ” I asked “ Oh, I just wanted to be reassured that it wasn't hæmorrhage ” I insisted on the injection which *she* insisted made her arm feel numb Throughout the performance her husband, imbecile and adoring, held both her hands “ You'd better have a baby,” I said, “ that would stop all this nonsense ” “ Oh, doctor,” she giggled, “ you're putting ideas into my head ! ” “ Impossible,” I muttered as I swept out

---

Certified causes of death in Denmark for the first quarter of 1942 were Infant disease 566, meningitis 10, scarlet fever 14, whooping cough 28, diphtheria 17, measles 10, poliomyelitis 3, encephalitis 7, tuberculosis 347, cancer 1579, cardiac and vascular disease 2714, chronic alcoholism 14, violence 312 and suicide 133

Parliament

ON THE FLOOR OF THE HOUSE

MEDICUS M.P

Mr Bevin, introducing the new National Service Bill, spoke of the gravity of the man-power situation and the necessity of full military training before the age of 19 when young men may be sent overseas either in units or as reinforcements To get the preliminaries of call-up and medical examination finished before the eighteenth birthday an earlier call-up, after examination at $17\frac{8}{12}$, is needed

Many members expressed disquiet and the debate turned almost wholly on educational and allied matters and not on the bill itself There will be sweeping changes in university life Medical, dental and some classes of scientific and technical students will continue their studies, but for the most part all arts courses will go, although there will be women, unfit younger men and older men still able to carry on The bill also affects older men to some extent There is no guarantee that men over 37 will not be called up if they are needed for special jobs But the modern army demands youth Even senior administrative officers are looked at askance as they approach the fifties and in the infantry, commando and other active units people may be heard being seriously perturbed over "old men" of 31 Britain gearing up for still greater offensive action needs a physical machine of the highest standard of fitness

Another piece of legislation just passed is an amendment of the legislation dealing with workmen's compensation The anomaly of the dust disease of the lungs which is caused by something other than silica has been removed All forms of pneumoconiosis will in future come under the Workmen's Compensation Act in so far as they are within the purview of the report of the medical inquiry published earlier this year Mr Grenfell, former minister of mines, welcomed the proposals but thought we had not yet come to the end of the road And in this he is right not only for miners and quarrymen but also for others working in great amounts of dust The special fund created to enable men who have left the industry, and are yet affected by pneumoconiosis, to claim compensation is a valuable extension of social insurance

Other anomalies of workmen's compensation are also remedied in this bill but when Mr Clement Davies said that the Workmen's Compensation Act was obsolete and out of date as compared with those of other countries he was coming near to the truth But the atmosphere of the debate was as it were charged with knowledge of the Beveridge report which puts workmen's compensation into a new perspective as part of an all-embracing social security scheme When the Beveridge scheme does come up for discussion in January or February the workmen's compensation part of it will be important

Another debate promised for the New Year is on medical relief for Europe on the cessation of hostilities The Leader of the House was asked about this at question time and is known to be willing for a debate to take place if the priority demands of other business allow Mr Dalton, president of the Board of Trade, has taken this subject under his wing and a great deal of work has been going on behind the scenes

FROM THE PRESS GALLERY

Debate on Venereal Disease

In the House of Lords on Dec 8 Lord **Winster** opened a debate on the increasing incidence of venereal diseases in this country which is causing widespread concern among members of both houses Although the increase, he said, was not so great as during the last war, the position was serious and urgent During 1941 7300 new infections of syphilis among civilians were treated at clinics Experience showed that there were eight cases of gonorrhœa for one of syphilis, which would give 60,000 cases in that year, a total of upwards of 70,000 new infections in 1941 These figures showed that during the war syphilis had increased by 50% among civilians, and adding the Services the increase was about 70% But so great was the secrecy surrounding these diseases that this might well be an under-estimation Many of the young Service people from overseas from countries where notification of these diseases compulsory Lord Winster felt that we had a duty them to do something more than issue a regulation the limited scope of 33B Medical knowledge adequate, but continuous and early treatment must assured Lord Winster admitted that the Ministry Health had watched the situation carefully, and treatment facilities in the big towns were now rea satisfactory, but he contrasted our rather f publicity with Scandinavia's realistic and suc propaganda The British Council for Social H felt that there were still gaps in the treatment which ought to be filled before compulsion was r to In the meantime regulation 33B was a step in right direction, but it could only operate when mischief existed in an aggravated form, and it only on treatment and cure We heard much in these days about freedoms, but he did not think these freedoms should include freedom to spread disease among innocent people and children

The **Archbishop of York** approached the problem from the religious rather than the medical point of view, but as he pointed out there need be no inconsistency between the two The Churches would support a bold and enlightened policy of education provided that prevention and avoidance of promiscuity was urged as the best safeguard of all There should be more treatment clinics and local authorities should be encouraged to employ more women police He had doubts about the practical working of regulation 33B, and he questioned whether it was possible to enforce compulsory treatment in our crowded country While there was any chance of voluntary action succeeding he was against compulsion, but if the diseases continued to increase it would be the clear duty of the Government *to consider compulsory notification for the civilian population*

Viscount **Dawson of Penn** said the increases were chiefly in the ports , in seven ports comparing 1939 and 1941 there was a rise from 942 to 1909 Among civilians there had been a steady increase of treatments among women—45 9% in syphilis and 29 3% in gonorrhœa Thus we were not dealing with the same problem as our forefathers even in the last war The women open to contract these diseases belonged to more classes than they used to do The prostitute class, who gained their livelihood by promiscuity, was decreasing The so-called amateurs were most dangerous because they were likely to give disease where it was least expected But there was an increasing number of venereal infections among girls of good repute, who would no doubt later become mothers If good treatment was available he was sure both women and men would take advantage of it We had precise knowledge both of the cause and of the treatment of syphilis and gonorrhœa Both started as local diseases, and this gave a good chance of catching them up, but if neglected they tended to become constitutional During the last war there was an outcry against a proposal to set up preventive ablution centres because of the old principle "you must suffer for your own deeds" The problem was solved with a characteristically English evasion and the centres were renamed "early treatment clinics" Lord Dawson was convinced that fair and considerate attention given to a man or woman's body never had anything but good effect on that person's mind, and he could not see how this illness could logically be treated except under the public health acts in the same way as other infectious diseases Since 1936 health authorities had power to take care of people if they were unable to take care of themselves If a person was verminous or suffering from scabies that person could be taken for treatment to a public institution Likewise an infectious patient could be removed from a factory, then why should not the same system be applied to venereal disease? There were two difficulties Up to now venereal diseases had not been notifiable, and he agreed that if notification was insisted upon people would be more frightened and anxious lest they should be discovered But treatment was different There was a hard core of irresponsibles that must be dealt with In his judgment 33B was a right and wise regulation from which a further step could be taken if necessary Lord Dawson spoke ly on the need to preserve secrecy That was one his reasons for hesitating to support compulsory ation Since secrecy was promised some years in connexion with venereal disease there had been he ght, three occasions on which secrecy had been thrust aside in a Court of Justice There was the Guildford case, where a man was asked to produce the secret books of a clinic If only a medical man would refuse to violate secrecy in these cases it would bring the whole business to an end In his view it was worth while to consider soberly the general question of medical privilege involved Lord Dawson declared in favour of the establishment of more clinics, but reminded their lordships of the grave depletion of the medical profession at the present time He was confident that the best that could be done was being done

Lord **Atkin** thought that regulation 33B was moderate and modest in form He was prepared to go further A professional prostitute found soliciting, who was infected with VD, ought to be compulsorily treated It ought to be made an offence for anybody who had reason to believe that he was suffering from VD not to submit himself to treatment Once a patient had been to a doctor or a clinic it should be easy to secure continuity of treatment by law Lord Atkin considered that medical privilege was a national necessity

The **Bishop of Norwich** in a maiden speech said that he understood that in England outside of London there were 160 venereal disease treatment centres before the war Today there were 175, an increase of only 15

Lord **Mapley** admitted that education in prevention was a difficult subject but suggested it is always better to put up a fence at the top of a precipice rather than provide an ambulance at the bottom

THE GOVERNMENT'S POLICY

Lord **Snell** said the official policy in relation to venereal disease was effectively to control it and if possible, to destroy it It was based on the principles laid down by the Royal Commission of 1913–16 voluntary attendance for treatment, free treatment available for everyone, free laboratory facilities for diagnosis for all practitioners. prohibition of treatment by unqualified persons, education of the public At present there were 249 clinics in Great Britain where free and confidential treatment was given, 18 new clinics had been opened since the war began 5 were now being prepared and would shortly be opened and a new scheme had been started for rural areas providing free treatment under practitioners with special qualifications There were [illegible] such special practitioners serving 74 areas in 11 different counties Special attention was also being given to the Merchant Service in ports The Ministry of Health took the view that the lower rate of incidence of VD in Sweden, where there was compulsory notification might not be the result of compulsion Sweden had a small population scattered mostly over rural areas with a highly developed sense of communal responsibility and of health consciousness The Ministry of Health was doubtful whether the Swedish experience would be repealed in our own country, Regulation 33B therefore left unchanged the voluntary basis of treatment The regulations had been carefully framed to secure equality of treatment for both men and women The whole question was surrounded by immense difficulties and there was a real need for a new and saner outlook in regard to it He would be afraid to trust himself to speak about the injury done by self-righteous Pharisees The psychology of both the sufferer and the community must be altered As Lord Dawson had said, VD was now responsive to treatment and the health authorities had had the whole-hearted cooperation of the medical profession

QUESTION TIME

Clean Milk Regulations

Mr R **Purbrick** asked the Minister of Health whether he would set out in detail the steps taken by his department in connexion with the production and distribution of cow's milk in a clean and healthy condition and state the various regulations made by his department for this purpose —Mr **Brown** replied The hygienic quality of milk is the subject of various provisions of the Food and Drugs Act, 1938, and of orders and regulations made under, or kept in operation by virtue of, the act These are mainly the Milk and Dairies Orders, 1926–38, and the Milk (Special Designations) Regulations, 1936–42 They are executed and enforced by local authorities The following are the principal relevant provisions —

Registration —No person may carry on the trade of cowkeeper or dairyman or use any farm or other premises as a dairy unless he and the premises are registered with the local authority A local authority may, in the case of persons applying to be registered or registered as retail purveyors of milk, refuse to register or cancel the registration if they are satisfied that the public health is, or is likely to be, endangered by any act or default of the person concerned A person aggrieved by any such decision may appeal to a court of summary jurisdiction

Conditions and methods of production —The Milk and Dairies Order 1926 contains a series of provisions with regard to cleanliness and methods of production, &c For example, certain requirements are laid down for the lighting ventilation and cleansing of cowsheds and buildings used for keeping milk, and for methods of milking Requirements are also laid down for cooling and for preventing the contamination of milk and for the cleansing of all churns, vessels or other utensils with which milk may be brought into contact

Conveyance distribution &c —Special provisions are laid down with regard to cleanliness and avoidence of contamination of milk in connexion with premises used for the sale of milk and in connexion with its conveyance and distribution

Infected milk —A supply of milk may be temporarily stopped if the medical officer of health has evidence that infectious disease has been caused by it or that the milk has been infected with such disease It is further an offence to sell for human consumption or use in the manufacture of products for sale for human consumption the milk of a cow which has given tuberculous milk or is suffering from certain specified animal diseases

Milk (Special Designations) Regulations —These regulations establish three grades of milk for which the special designations are tuberculin tested accredited and pasteurised It is unlawful to sell milk under these designations except in accordance with a licence Licences are granted in the case of producers by county and county borough councils Licences for dealers bottlers and pasteurising establishments are granted by borough, urban and rural district councils An appeal lies to the Minister against the refusal suspension or revocation of a licence by a local authority Tuberculin-tested milk is the milk of cows which pass a tuberculin test and a periodical clinical veterinary examination The milk must also comply with a prescribed test for cleanliness and keeping quality Accredited milk is the milk of cows which pass a periodical clinical veterinary examination and is subject to the same cleanliness test as is tuberculin tested milk Pasteurised milk is milk which is treated in accordance with one of two prescribed processes and it must also comply with a bacteriological test

Replying further to Mr **Purbrick**, Mr **Hudson** said that the administration of regulations as to the production of cow s milk in a clean, healthy condition was a matter for the Minister of Health but the Ministry of Agriculture was now administering a scheme under which milk should be tested at the point of first delivery as to its keeping quality The scheme was devised to ensure that sour milk should be kept off the liquid-milk market, and particularly that sour milk should not be bulked with clean milk and thus contaminate considerable quantities on the way to the consumer In the case of all samples of milk found by the test to be unfit for the liquid-milk market, notification was made to the county war agricultural executive committees so that the producers concerned could be visited and advised on how their method might be improved This scheme did not replace any existing legislation with regard to milk.

Shortage of Pasteurisation Workers

Mr **Arthur Hollins** asked the Minister of Labour whether his attention had been called to the report of the Committee on Tuberculosis in War time, in which attention was called to the serious depletion of skilled workers in the pasteurisation processing depots, and whether he was prepared to implement the proposals that specially skilled workers in these depots should be placed on the list of reserved occupations and that workers in this category who had already been called up should be returned to their posts —Mr **Ernest Bevin** replied My attention has been called to this report but I am not aware of any excessive depletion in the numbers of skilled workers engaged in milk pasteurisation. I consult the Minister of Food before calling up workers from this industry As regards release from the Forces, it would only be in cases of clearly proved necessity that I should feel able to recommend such action to the Secretary of State for War, in view of the requirements of man power for the Forces Dr **Russell Thomas** Does the Minister not think that the time has arrived to consult the Minister of Agriculture and the Minister of Food in order to secure the production of clean fresh milk instead of constantly subjecting milk to these artificial processes ? No further reply was given.

Extension of Clyde Valley Medical Service

Mr F W **Pethick-Lawrence** asked the Secretary of State for Scotland whether he had extended the area of the experiment in diagnosis and treatment of workers initiated in the

Clyde Valley, and if he would give the areas which the scheme now covered —Mr T JOHNSTON replied The supplementary medical service which has operated in the Clyde Valley since January last has now been extended to cover workers of all ages in the industrial areas of Scotland —Mr PETHICK-LAWRENCE Has the concurrence of the medical profession been obtained, and what is the approximate number of workers affected ? Mr JOHNSTON I have the entire concurrence of the medical practitioners I cannot give the precise number of workers covered by the extended operations of this act, but the first experiment covered 44% of the insured workers Dr E SUMMERSKILL Does this extension include dependants ? Mr JOHNSTON It deals only with workers, but it includes a housewife if she is a war worker

Mr H MCNEIL Is the Minister satisfied that there are sufficient beds to meet all kinds of cases referred for hospital treatment under this scheme ? Mr JOHNSTON Absolutely

Post-vaccinal Deaths in Scotland

Mr S P VIANT asked the Minister how many deaths had occurred during the recent smallpox outbreaks from vaccination and with vaccination as a contributory cause, respectively —Mr JOHNSTON replied According to the information at present available there have been 9 deaths in Scotland following vaccination during the recent outbreaks of smallpox, when about a million vaccinations were performed Seven of these were registered as due to encephalitis (2 in Glasgow, 3 in Edinburgh and 2 in Fife), 1 in Glasgow due to erythema and 1 in Lanarkshire due to toxæmia In addition there was 1 death in Glasgow due to measles, vaccination being stated to be a contributory cause

---

Letters to the Editor

LABORATORY TECHNICIANS OF THE FUTURE

SIR,—It would be unfortunate if your annotation of Nov 28 (p 649) should give the impression that the Association of Scientific Workers (AScW) has completed the formulation of its policy to improve the status and education of technicians, or is committed to some of the proposals criticised in your article A memo on this subject is at present being considered by a joint subcommittee of the science education, medical sciences and technicians committees of the AScW When a final report has been prepared and approved it will be sent for criticism and suggestions as to appropriate action to other interested bodies, such as the Institute of Medical Laboratory Technology (when established), the Association of Clinical Pathologists, and so on Although the AScW hopes that improvement in the status and education of technicians can be inaugurated in the near future and is working towards that end, it should not be assumed that the statements mentioned in your annotation represent its considered policy

DOUGLAS MCCLEAN,
Chairman of Medical Sciences Committee

Association of Scientific Workers,
High Holborn, WC1

SIR,—Your annotation on laboratory technicians appears to me to discover difficulties where none need exist The supply and training of laboratory assistants have been solved at this hospital and the routine adopted may be of interest to other hospitals The laboratory is under the charge of a part-time pathologist and is run by a full-time technician who now has the diploma of the PBLAA When it was found necessary to expand the staff a lad of 16 of matriculation standard was engaged as an apprentice under a three-year agreement The hospital undertook to supply instruction and make him competent as a technician, paying him 10*s*, £1 and 30*s* a week for the three years, he on his part undertook to attend technical college evening school and to sit for the two parts of the diploma in three and five years At the end of three years he passed the first part and was given a further agreement at £2 a week, rising by two annual increments to £3 a week at the age of 21 An additional apprentice was engaged

Such a system supplies a continuous series of recruits at little cost and yet making the employment worth while, with its prospect of entering what is becoming a remunerative profession At the same time insistence on the seniors carrying out teaching quickens their interest and leads to better work It appears to me unnecessary to insist on training at only a few cent "offering considerable facilities for teaching" T PBLAA already has an effective routine for the dir tion of training, for examination and qualification its members

General Hospital, Halifax H I DEITCH

EASY CHILDBIRTH

SIR,—The review of Dr Dick Read's *Revelation Childbirth* in the *Lancet* of Nov 28 prompts me to p down my experiences during the birth of my first ba two months ago Up to the fourth month of m pregnancy I was terrified of labour, having seen what thought to be unbearable suffering while doing m midwifery cases (I am a final-year student) Then read Dr Dick Read's chapter on relaxation in F Browne's *Antenatal and Postnatal Care* (1942, p 7 His argument appeared reasonable, and from th moment I made up my mind to have a painless a normal labour

Labour started at 3 30 AM I noticed that the pa were merely uncomfortable while lying down whereas pa was very real when walking about, because then I w unable to relax properly When I got into bed at the hospi I read an ear, nose and throat book much to the amuseme of everybody Sister came to see how I was getting on eve hour or so I was having fairly frequent pains at the tim, but she thought I was telling stories At 2 PM the registrar arrived to have a look at me Sister was sure I was "not doing anything," or how could I be reading about otitis media ? I told him I had read the article on relaxation in Browne and was trying to act accordingly He smiled indulgently and later told Sister that in that case one did not really know how far on I was, but still he did not think much would happen for many hours At 3 PM the ward maid asked why I had come in if I was not in labour At 4 PM I was moved into the labour ward I had previously asked for the 'Minnitt' but after two attempts gave it up as unnecessary The end of the first stage was the only really uncomfortable time At 5 PM the HS told me I need not be brave and should scream as much as I liked, they would give me a whiff of chloroform when the head was being born He thought me mad when I refused because I wanted to hear the first cry During the end of the first stage and throughout the second stage I found two things extremely important first, though I knew what was happening and was not frightened, it was terrifying to be left alone in the room, secondly, it was important that there should be somebody's hand to hold while pushing The second stage lasted 50 minutes As long as I pushed as hard as I could during pains and relaxed completely between them it was not painful at all, only if I did not push hard for just a moment was it painful I certainly did not find the crowning of the head "a moment of extreme agony for the mother" The feeling of relief afterwards was indescribable

The staff, and particularly the midwives, were impressed by the fact that a normal labour of 15 hours duration could be so painless "Relaxation" was a topic of conversation in the hospital for the next few days A friend of mine who was having her first infant about the same time had similar experiences both as regards painlessness and the incredulity of the midwife

To sum up most doctors and midwives regard labour as necessarily very painful, but, judging from my own case, relaxation during the first stage and hard pushing during the second make labour almost painless except for the last few pains of the first stage Anæsthesia or even analgesia is not necessary in a normal labour It should be a rule that a woman in labour should never be left alone

ELENA ZADIK

MERCURIAL DIURETICS

SIR,—In your annotation of Nov. 28 (p 651) you point out that the number of recorded fatalities is astonishingly low considering the wide use of mercurial diuretics Among more than 5000 injections of mersalyl, 'Novurit,' 'Neptal' and 'Esidrone,' given or watched by myself, I remember only few untoward and no fatal reactions Of the two types of toxic reaction—that due to the mercury and that due to the diuresis—the latter is much rarer than the former When these drugs were first used there was much speculation about the risk of cardiac asthma and dehydrational shock from over urdening the left ventricle and sudden fluid mobilisa-ion, I have never seen such effects Dehydrational sychosis occasionally occurs, as does renal colic from shifting calculi The toxic effects are less uncommon and I would like to add to the four main causes mentioned in your article a fifth, possibly more common than any other—namely, the repetition of an injection after one or more have been given without diuretic effect The reasons of failure are various and immaterial to the outcome The cause of the intoxication is accumulation of the drug from retention in the absence of diuresis In desperate cases this complication cannot always be avoided, but its possibility should be borne in mind

Febrile reactions, even after correctly applied injections, may occur in cases of chronic infection, and the mercurials should as a rule not be given for tuberculous or carcinomatous effusion, or for polyserositis In a case of syphilitic aortitis under my care fever, with a rigor, followed each injection of novurit without any other untoward symptoms and an abundant diuresis resulted each time Prolonged treatment with mercurial diuretics may produce emaciation, probably from acidosis and dehydration, especially in non-cardiac cases Experience suggests that injections should not be given more often than every fourth day in chronic cases

Stratford on Avon Emergency Hospital MAX WINTERNITZ

INEFFECTIVE PESSARIES

SIR,—Within the last few weeks I have noticed an increase in the number of patients who have started an undesired pregnancy in spite of using quinine pessaries I am told that these are widely advertised, that " the Army " has complete confidence in them, and that " the Medical Officer " recommended them as reliable It is surely agreed among the profession that safety can only be assured by the use of both an occlusive pessary and a spermicidal paste or tablet together This knowledge should be used to prevent the distress and danger which is following the public's misplaced confidenc in medicated pessaries

Hove, Sussex LILIAS M JEFFRIES

Obituary

FRANK CECIL MAYALL BAMFORD

MB GLASG, SURGEON COMMANDER, RN

Surgeon Commander Bamford, who was killed in action during April, qualified at Glasgow University in 1926 The last war had found him as a youngster in Berlin, where he suffered the trials of internment On his return he matriculated at Glasgow and joined the University OTC, but the war ended before he was called for active service and he returned to his medical studies After holding a house-appointment at the Western Infirmary, Glasgow, in 1928 he entered the Royal Navy with which he had family associations His first appointment was to the Kai Tak aerodrome, Hong-Kong, and from there he was posted to HMS *Herald*, then on a survey commission off the Borneo coast In April, 1933, he was promoted to the rank of surgeon lieut-commander, and after a period in the naval dockyard at Chatham he served on the hospital ship *Maine* in the Eastern and Western Mediterranean until 1938 Promotion to surgeon commander came in the spring of 1939 and at the outbreak of war he was at the RN barracks at Chatham In June, 1940, he joined HMS *Dorsetshire* and saw service in Eastern waters as well as the rounding up of the German pocket battleship *Bismarck* Bamford had travelled a good deal in Europe, where he had many family ties He was an ideal companion and a friend who recalls several holidays spent wandering with him about the Continent writes " Under Bamford's somewhat shy and retiring disposition there lay a generous nature which showed itself in kindness and consideration to those around him, particularly to those less favoured by fortune He had a lively imagination, a profound sense of humour and a warm sympathy " His captain's words at the time of his death sum up his character Seldom have I met a man with more consideration for others and less for himself

In June, 1941 Bamford married Beatrice, younger daughter of the late Sir John Train, of Rutherglen Lanarkshire

RUSSELL JOHN HOWARD

CBE, MB LOND, FRCS

Mr Russell Howard, consulting surgeon to the London Hospital, who died at Oving, Bucks, on Dec 2, was one of those men that create the atmosphere of their hospital and represent it afterwards in the minds of their students Born in 1875 he was educated at King's College School and graduated MB with first-class honours from the London in 1899 Four years later he was awarded the gold medal when he became MS and in the same year he also obtained his FRCS His whole life was bound up with his hospital and the terse entry in the medical directory—surgeon, lecturer in surgery and house-surgeon to the London Hospital—proudly sums up his career When the time came for him to retire he felt that a vital part of him had been lost and it was with delight that he received the call to go back to teach for what were to be the last months of his life He had evolved a technique that effectively instructed the majority and his out patient clinic and ward round were attended by people of every race and colour, while his *Practice of Surgery*, first published in 1914, shows the simplicity and reasonableness of a great teacher

Wherever two or three from the London are gathered together the talk eventually turns to Russell John's forcible sayings and sound advice, and one of his flock writes A large frame, small hands and feet (of which he was pardonably vain), a pair of eyes alternately penetrating and merry, a crisp, cockney voice and a brilliant smile were some of Russell John's presenting characteristics Energy, vitality, humour, and an acute awareness of the things going on around him were others, he certainly didn't miss much Above all things, perhaps, he hated intellectual dishonesty, mental slovenliness, woolliness and indecision, hence the blackboard in his operating theatre on which first the dresser, then the house-surgeon and lastly " the master " himself (as some of us called him) had to chalk up a diagnosis of each case before operation Hence also the following dialogue, so often-repeated almost word for word either in OP's or at the bedside " What is wong (he couldn't roll his r s) with this patient ? " " Well, sir, it might be——" " I didn't ask you what it might be I want to know what it *is* " " I don't know, sir " " Of course you don't know But, Lordy me, you can have an opinion I used to be wrong ten times out of ten Now I'm only wrong seven times out of ten I'm improving and so will you if you stick to it ! " His " rags " at 9 o'clock on Saturday mornings —an unearthly hour for students, many of whom were living or digging an hour's journey from the hospital—were always packed to the roof with lambs only too keen to be verbally slaughtered in a merciless cross-examination, for they knew that the last quarter of an hour would be devoted to a succinct and masterly summary of the subject in hand His obiter dicta would make a book, and he had a genius for the reductio ad absurdum Thus, of the causes of acute intestinal obstruction " Let's start at the beginning—Imperforate anus ? H'm, rare I should say in a man aged 55 " Of nutrient enemata. " So you'd give him coffee per rectum, would you ? Would you put sugar and milk in it ? " Then turning to the patient, " D'you take sugar and milk ? " Of the occult blood test " If it's positive, all you know is that the patient is bleeding somewhere between his teeth and his anus, always provided that he hasn't got hold of a bit of meat and eaten it behind your back " Ex-house-surgeons and other privileged persons will recall exhausting week-ends, often after " full duty," of carpentry——but also the rewarding liqueurs—at his country house Most of all they will be grateful for the stark sense he taught them which has proved a sure basis of approach to every clinical problem that confronts them Of his loyalty and complete lack of jealousy it would be impertinent to speak

Notes and News

TOBACCO SMOKING AND NICOTINE

LENNOX M JOHNSTON, M B GLASG

ON the assumption that smoking tobacco is essentially a means of administering nicotine, just as smoking opium is a means of administering morphine, nicotine was given hypodermically to 35 volunteers in known doses with a view to comparing its effects, and particularly its psychic effects, with those of tobacco smoking, 7 received single doses but the others doses ranging in number from 2 to 35 Nicotine gr 1/50 given hypodermically to a non-smoker has a subtle psychic action difficult to describe "Swimminess," "muzziness," and "light-headedness" were the usual descriptions The action is specific and is readily distinguished from that of cocaine or codeine Whereas smokers almost invariably thought the sensation pleasant and, given an adequate dose, were disinclined for a smoke for some time thereafter, non-smokers usually termed it "queer" The sensation is usually perceived in about 5 min and lasts about 15 min There is some smarting at the site of injection and, a little later, pain may shoot proximally or distally along the limb Nicotine, gr 1/40, usually gives rise to toxic symptoms in a non-smoker, but gr 1/10 can be given to heavy inhalers or pipe smokers an hour after a smoke without toxic symptoms supervening A considerable tolerance to nicotine is therefore acquired as a result of smoking Toxic symptoms consist of excessive "swimminess" (unlike vertigo), rapid and forcible cardiac action, nausea, vomiting, and syncope

Although the percentage of nicotine in tobacco varies from 0 5% to 5%[1] it was found that as a rule the subjective sensation induced by one deep inhalation of cigarette smoke was closely simulated by the intravenous injection of gr 1/500–1/750 of nicotine This observation tended to confirm a previous one—namely, that the cumulative psychic effect of a cigarette inhaled (approximately 12 inhalations) closely resembled that of gr 1/50 of nicotine hypodermically Nicotine action is perceived in about 15 sec both on the inhalation of tobacco smoke and on intravenous injection of nicotine and may last for 1 or 2 minutes

In pure solution and well diluted, nicotine may be given orally In 5 oz of water gr 1/15 tastes of tobacco but is not particularly disagreeable, it induces an effective psychic action in about 15 minutes Stronger solutions tend to bite the throat Rough comparison suggests that when an average pipe or cigar is smoked fully gr 1/10 of nicotine is administered orally I gave myself 80 hypodermic doses of nicotine at the rate of 3 or 4 a day with some smoking, after this course I preferred a hypodermic injection of gr 1/50 of nicotine to inhaling a cigarette, and feelings of deprivation were experienced when the drug was discontinued Nicotine was given orally in doses of gr 1/15 three times a day to an old-standing case of neurosis, without the patient's knowledge She declared it was stronger and "steadied" her more than phenobarbital (gr 1) although it was less hypnotic She resented its withdrawal after some 80 doses

Cigarette inhalers perceive comparatively little of the "swimmy" sensation of nicotine, unless with the first few inhalations in the morning, and there is no doubt that much of the satisfaction of smoking lies in the appeasement of craving

DISCUSSION

It seems probable theoretically, that satisfaction is caused by the stimulation of sensory cells in the brain and that craving is the subjective manifestation of the depression which follows, for this depression the specific cure is further stimulation There is, however, a limit to the capacity of cells to respond to stimulation If therefore smoking is indulged in beyond this point there is no satisfaction It is clear, moreover, that the heavier the smoking the stronger the subsequent craving and the tendency therefore for heavier smoking to continue, which constitutes a vicious circle The strength of an addiction is measured by the difficulty in giving up a drug and it is difficult indeed for the inhaler or pipe smoker of many years standing to give up smo manently Strength of addiction is reinforced by formation and by mass suggestion from other Craving operates largely unconsciously and addicts usually unaware of their disturbance of judgment, many smokers will allege in all seriousness that t is due to damp, draughts dust, fumes, infection, "catarrh," or gas in the last war They will take manner of useless medicaments while rejecting and resenting the suggestion that smoking might be ible, that thought is so unwelcome that it is into the unconscious mind Even if this overcome it does not follow that appropriate action be taken Much oftener concern about the will be repressed, the symptoms now being a philosophically, while smoking continues It is therefore, that the statements of smokers on the of smoking on their health may legitimately be s Few addicts wish so strongly to give up their drug they are willing to overcome the inevitable feelings deprivation, but their health improves signally if drug is forcibly withheld Improvement in the particularly of cigarette inhalers, has been observed when they have given up smoking Some allege that their health has not improved, but the possibility that they are finding the struggle difficult, and unconsciously preparing an alibi for their eventual relapse, must be borne in mind Confirmed smokers who develop phthisis, peptic ulcer, bronchitis, or even tobacco amblyopia will rarely give up smoking except when their condition is grave, and even then usually only for short periods This non-cooperation in rational therapeutics arises from the craving for tobacco

SUMMARY

Nicotine was given hypodermically, in doses ranging from gr 1/50 to gr 1/10, to 35 volunteers, some being smokers and others non-smokers

Symptoms induced by the injections were described as "swimminess" or "muzziness"; large doses caused toxic symptoms in addition, including rapid and forcible cardiac action, vomiting and syncope Smokers could tolerate considerably larger doses than non-smokers

Intravenous injections of gr 1/500–1/700 induced sensations simulating those induced by inhalation of cigarette smoke Nicotine given orally—gr 1/15 in 5 oz of water—also had a psychic action

After a course of 80 injections of nicotine gr 1/50, an injection was preferred to a cigarette

Smokers show the same attitude to tobacco as addicts to their drug, and their judgment is therefore biased in giving an opinion of its effect on them, yet abstinence is generally followed by improved health

In conditions which would benefit by giving up smoking (phthisis, peptic ulcer, tobacco amblyopia) the confirmed smoker often will not abstain

CLYDESIDE SCHEME EXTENDED

THE Secretary of State for Scotland has announced that this scheme is being extended to cover all industrial workers north of the Tweed (see p 739) On Nov 27, a letter to insurance practitioners explained how diagnostic, consultant, hospital and convalescent facilities have now been opened to all insured workers in Scotland through the RMO service and the EMS Hospital Scheme They are no longer restricted to the young people of Clydeside Mr Johnston suggests a preference for workers with vague symptoms of fatigue or debility, and in mining areas for boys or young men who have recently entered the industry and show signs of unfavourable reaction to the work A report will be sent to his doctor after the patient's first examination and again on his discharge from hospital

BRITISH PROVIDENT ASSOCIATION

THE association has had a successful year and is able to offer an additional benefit to subscribers of three years' standing In future their benefit for hospital and nursing home service is to be raised from £5 a week to £7 7s Last year over £12,000 was distributed in benefits During the year subscribers were sent a questionnaire dealing with the position of provident schemes in the future medical services of the country and the executive council and the medical advisory board consider that their replies show that many peopl moderate means think the facilities for medical and tional treatment should be improved by the on of more accommodation at a reasonable charge by easing the financial burden of serious illness y subscribers also thought that the development of dent schemes providing free choice of doctor and tution should form an essential part of any improved ce

[1] Extra Pharmacopœia, Martindale 1941 vol I, p 867

MILK IN HOLIDAYS

As the Christmas holidays parents of school-children faced with the problem of how to supply them with milk which was a substantial addition to the school t. At state-aided day schools milk may be consumed the children in holidays or at week-ends provided children meet in an approved place to drink it y cannot have it at home Under the B of E inistrative memo no 410 (10 viii 42) the same ilities were extended to private schools as were eady available for the others and sanction was given r the bourgeois to drink milk provided they went to e same place as the proletariat Milk is thus put on e same footing as beer except that there is no saloon lk bar The boy home from boarding-school should ng with him a temporary ration document, obtained the school from the food office which will entitle m to all rationed and controlled foods, including 3½ ints of milk a week In theory he can obtain additional milk by presenting himself twice daily at the place pointed for elementary-school children, which will ually be the elementary school itself In practice the boarding-school boy will not get his "milk in schools" during the holidays Probably the difficulty of switching distribution from the school centre to the individual consumer would be insurmountable But another time it might be well to authorise the issue of an extra tin of dried milk to be brought home by the child from school

NUTRITION OF SANATORIUM PATIENTS

THE Minister of Health regrets that the "limitation of supplies and the necessities of others" do not allow an extra ration of eggs for the tuberculous (*Lancet* Dec 12, p 714) They do however get an extra allowance of milk Dr Lissant Cox, central tuberculosis officer for Lancashire, has made detailed investigations at two of the county sanatoriums into the gain or loss of weight of patients In the first six months of 1939 discharged patients had gained on an average 10 6 lb During 1941 the average gain was 5 2 lb, and for the first six months of 1942 5 3 lb So although their gain is less than before the war sanatorium patients are increasing their weight at a time when the rest of the population is, sometimes with advantage, losing weight The medical supts of the Lancs institutions, according to Dr Cox's interim report for 1941, consider that their patients are not suffering in health from rationing and that there is no evidence to justify asking Lord Woolton for a little extra for them

ALTERNATIVE KEY TO THE NEW AGE?

SOCIAL Credit failed in Alberta, where it was tried Mr C Marshall Hattersley in a pamphlet (*Now—or Never?* Swinton, Yorks SCCC 6*d*) proposing its immediate application here and suggesting possible postwar developments, states its principles Price-fixing, subsidy, purchase tax and rationing, he points out, are accepted in war-time, must they be thrown overboard when peace returns, and will slumps poverty unemployment and a new war complete the cycle? The Social Credit answer to the dilemma is set out here, though not very clearly It is also referred to by Dr A T Westlake (*The Social Credit National Health Service* London the Social Credit Party 3*d*) who defines the party's principle as "costless credit creation and cancellation on the basis of production and consumption recorded by national accountancy" The results, however, are to be a perfecting of national health achieved through going on much the same as usual only better Thus the general practitioner will be "a man of wide culture and possessed of imagination, sympathy and intuition, and a fertile philosophy of life", and he will live partly by a National Dividend in the form of free rations of food, clothing, fuel, shelter and petrol, and partly by credit vouchers for goods, and a graded salary The voluntary hospitals will be left to govern themselves as usual but their financial worries would be at an end it would all be done through a central health department, yet the administration would be decentralised, new schemes would be financed and new hospitals built by a process of crediting and cancelling sums in the books of the National Accounts Department It gives the impression of a brilliantly lighted scene without the least vestige of shadow

---

University of Cambridge

On Dec 5 the following degrees were conferred

MD—L J Bacon and R A Jones
MB BChir—T P Pattinson (by proxy)

University of London

Mr G A R Kon, D Sc, has been appointed as the first occupant of the university chair of chemistry at the Royal Cancer Hospital (Free), which was instituted just before the outbreak of war Dr Kon has been a member of the staff of the Imperial College of Science and Technology since 1925 and the title of reader in organic chemistry was conferred on him by the senate in 1935

Royal College of Surgeons of England

At a meeting of the council of the college held on Dec 10, with Sir Alfred Webb Johnson, the president, in the chair, diplomas of fellowship were granted to the following

R A Plachaud LM & S Ceylon, N F Kirkman, MD Manc, S C Mehta, LRCP Robert Roaf, BM Oxfd, J P Bentley MB Lond, B N Brooke, MB Camb, Walter Thompson MB Leeds D K Sambrook MB Lond, J P Childs BM Oxfd, H A Haxton, MB St And, and D K Lennox, MB Glasg

A diploma of membership was granted to G H V Clarke, and diplomas in anæsthetics were granted jointly with the Royal College of Physicians to the following

E H Ainslie Evelyn J Atkins, L B Bourne Albert Christie P J De Vescovi James Elliott G A Hart J A G Horton, Brenda G Hutchinson, I R Jones H G Kahlenberg Isabelle G Little Florence M McClelland Margaret McClelland T F Miles, Dorothy S Price, F N Price Shila G Ransom Alice C Rose, J B Scarr, Thomas Sim A D H Simpson Dorothy Spence Sales R J Stout C G Townsend, J T Worsfold and Jean R Young

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on Dec 7 with Mr James H MacDonald, the president, in the chair, the following were admitted to the Fellowship

John Black, MB, Glasgow; Charles Borg, MD Richmond G G Browning MB Glasgow A J V Cameron MB, Clydebank G M Currie MB Kilmarnock Aloysius Dunn, MB, Glasgow and H B Young MB Glasgow

American Ophthalmological Congress

The second meeting of the Pan American Congress of Ophthalmology will meet in Montevideo, Uruguay, from Nov 4 to 7, 1943 The executive secretaries are Dr Conrad Berens, 477, First Avenue, New York, and Dr M E Alvaro, Consolacao 1151, Sao Paulo, Brazil

Czechoslovakian Unit in London

At the request of the Czechoslovak government 60 beds at Hammersmith Hospital were opened on Dec 1 for the use of Czechoslovakian Service and civilian patients

Edinburgh Child Health Centre Opened

On Nov 30 new premises for the Edward Clark chair of child life and health at Edinburgh University were formally opened by the Secretary of State for Scotland Sir Thomas Holland, vice chancellor, who presided, gave an account of the foundation of the chair and the pioneer work of Dr John Thomson, he thanked the directors of the Royal Edinburgh Hospital for Sick Children for the facilities for study and teaching that had been and were being provided Prof Charles McNeil recounted the development of the health side of the chair, the aim, he said, was to set up a department of child health, based upon the clinical material in the new-born nurseries of the maternity pavilion of the Royal Infirmary and of the infants returning to the welfare clinic in the pavilion Their immediate problem was that of infant and neonatal mortality The new premises would be a training-school for doctors and nurses concerned in the care of children, and a centre of study and investigation of all problems bearing on child health The new department was already linked with the obstetrical staff of the pavilion It now desired cooperation with the child welfare and school medical services of Edinburgh Corporation, and with the general practitioners of the city Lord Provost Darling said the corporation fully appreciated the importance of child life and would be glad to coöperate with the university in the promotion of child health Mr Johnston, declaring the centre open, said the high infant death rate in Scotland was lamentable and a matter of grave national concern he had appointed a committee to investigate its causes and to suggest remedies, and the Department of Health would be glad to give assistance to the joint contribution of city and university to the national problem

Medical Supply of Radon

Radon having largely replaced radium element as a therapeutic agent under war conditions, the National Radium Commission and the Medical Research Council have made themselves jointly responsible for its production at convenient centres Since radon treatment carries with it the same risks as radium treatment, radon will now be supplied only to hospitals which have been approved by the Radium Commission It will not be supplied direct to individual clinicians Approval postulates a properly equipped radiotherapeutic department, with a radiotherapist and a physicist as part of the staff, and an organised follow-up of patients treated by radiotherapy

An Anti-Tuberculosis League for Ireland

On Nov 19 a meeting of the medical and veterinary professions was held at the Royal College of Physicians of Ireland under the chairmanship of Dr R J Rowlette, PRCPI, to discuss the establishment of a national anti-tuberculosis league The large attendance included representatives from Northern Ireland, headed by the chief tuberculosis officer for Belfast, and the proposal to form the league was unanimously approved It was decided to summon a meeting open to the public as well as members of the two professions early in the new year, when the league will be formally inaugurated and officers and committees appointed The new league hopes to educate the public in tuberculosis matters, stimulate research, collect trustworthy statistics, and press for adequate hospital and sanatorium accommodation

London Fog

During the fog of Nov 11–12, between 6 PM and midnight, 96 accident calls and 21 general calls—three times the usual number—were dealt with by the London ambulance service Auxiliary ambulances, normally reserved for air raid casualties, were brought into use and many of the crews acted as guides One ambulance, for instance, progressed along a main thoroughfare convoyed by nine men and women with torches—a trip of 1¾ miles which took 1 hr 40 min Besides accident casualties, maternity patients, midwives, infectious patients, and stranded wayfarers, were fed, tended, cheered, and where possible helped on their way

LCC Pathological Demonstration

On Dec 2 the London County Council Pathological Service gave a series of lectures and demonstrations at the Group Laboratory, Lambeth Hospital, to pathologists and consultants of the Royal Canadian Army Medical Corps and the United States Army Medical Corps, 16 Canadians and 9 Americans were present They included Colonel J A Macfarlane, consulting surgeon, and Colonel L C Montgomery, consulting physician, and Lieut-Colonel M H Brown, assistant director of hygiene, Canadian Forces With the American pathologists was Major Ralph Muckenfuss now in charge of the US General Medical Laboratory "A" The visitors were welcomed by Dr Andrew Topping, deputy medical officer of health, and in the morning a series of short papers were read by Major J E McCartney, Dr Robert Cruickshank, Dr W W Kay and Dr R F L Hewlett The work of the council's hospital service, with 35,000 beds for acute and chronic sick and 30,000 beds for mental diseases, and of the council's pathological service was explained The latter comprises 28 pathologists and assistant pathologists, 105 laboratory technicians, and 72 others (clerical, domestic, drivers and stablemen) The pathological staff for the mental hospitals is not included in these figures

At lunch the visitors were joined by Mr E C H Salmon, clerk of the LCC, and Dr W Allen Daley, the MOH, both of whom addressed the gathering In the afternoon the council pathologists and their staffs gave a series of demonstrations showing the work of the LCC pathological service, including culture media, leptospiral and salmonella infections, liver-function tests, blast and crush injuries, malignant cells in sputum, sternal puncture, estimation of sulphonamides, neisseria and hæmophilus infections, typing of streptococci, diagnosis of intestinal infections and use of desoxycholate medium. diphtheria diagnosis and antistreptolysin titration

Infectious Disease in England and Wales

WEEK ENDED DEC 5

Notifications—The following cases of infectious were notified during the week smallpox, 0, fever, 2900, whooping-cough, 1195, diphtheria, 1011 paratyphoid, 5, typhoid, 4, measles (excluding ella), 11,205, pneumonia (primary or influenzal), 890 puerperal pyrexia, 145, cerebrospinal fever, 73, myelitis, 11, polio-encephalitis, 0, encephalitis argica, 3, dysentery, 191 ophthalmia ne 73 No case of cholera, plague or typhus fever notified during the week

Deaths—In 126 great towns there were 2 (0) from enteric fevers, 3 (0) from scarlet fever, 15 (1) from measles 8 (0) from whooping-cough, 22 (2) from diphtheria, 58 (8) from diarrhœa and enteritis under years, and 33 (6) from influenza The figures in parentheses are those for London itself

Birmingham reported 6 deaths from diarrhœa, Manchester no other great town more than 3

The number of stillbirths notified during the week was 221 (corresponding to a rate of 33 per thousand total births), including 21 in London

By Dec 11 the total number of deaths from smallpo reported from Edinburgh was 6

For some months past there have been many cases poliomyelitis in various districts of Ireland, but recen reports give hope that the epidemic is dying out Th disease had the highest incidence in some of the wester counties, notably Clare and Roscommon, but it was no limited to any area From July 1 to Nov 7, 137 case were reported (37 in the city of Dublin with 34 deaths For the four weeks prior to Nov 7 the numbers reporte were 28, 17, 18 and 22 In the week ended Nov 2 only 5 cases were reported

The fact that goods made of raw materials in shor supply owing to war conditions are advertised in thi paper should not be taken as an indication that they a necessarily available for export

Appointments

CROOKS, FREDERICK, MCH BELF, FRCSE medical referee for th county court districts of Newark and Nottingham (circuit 18)

THOMAS, E W, MB GLASG, FRCSE, FRFP & S RSO at the municipa general hospital, Burnley

WARD MARY E E, MB LOND psychiatrist to Berks child guidanc clinics

Births, Marriages and Deaths

BIRTHS

HOPKYNS—On Nov 30, at Colchester, the wife of Surgeon Lieu tenant J C W Hopkyns RNVR—a son

MALLINSON—On Dec 8, at Sittingbourne, the wife of Dr F M Mallinson—a son

MATHISON—On Dec 11, at Darwen, the wife of Surgeon Lieutenan Alex Mathison, RNVR—a daughter

MILLING—On Nov 20, at Woking, the wife of Dr P F Milling— son

PATRICK—On Dec 3, at Amesbury, the wife of Captain H L Patrick RAMC—a daughter

PENROSE—On Dec 4, at Banbury, the wife of Dr T H Penrose—a son

SCADDING—On Nov 30, in London, the wife of Lieutenant F H Scadding RAMC—a daughter

VAILE—On Dec 5, at Addlestone, the wife of Dr John Vaile of Chertsey—twin sons

WOLSTENHOLME—On Dec 8, at Whitby the wife of Major G E W Wolstenholme, RAMC—a daughter

MARRIAGES

LANDELLS—NEVILLE SMITH On Dec 3, John Wingrave Landells B CHIR, captain RAMC, to Norah Neville Smith

RANKIN—WAINWRIGHT—On Dec 8, at Wembley, Alan Clement Raleigh Rankin, MB, major RAMC, to Joan Wainwright

THOMPSON—HULL—On Dec 10, in London, Vernon C Thompson FRCS, to Jean Frances Hull

DEATHS

CRAWFORD—On Dec 9, at Mount Park Road, Ealing, Dirom Grey Crawford MB EDIN lieut colonel IMS retd, aged 85

CUFFE—On Dec 4, Alexander Cuffe, MD DURH, FRCSI, of Vange, Essex aged 79

MINCH—On Nov 8, in India, John Berchmans Minch, MB NUI lieut colonel RAMC

MITCHELL—On Dec 10, Charles Robert Paterson Mitchell, MD EDIN, MOH of Malvern

RITCHIE—On Dec 6 in London, Alexander Lumsden Ritchie, MB ABERD of Cavendish Suffolk

SWEETNAM—On Dec 6, Stephen Westrope Sweetnam, MRCS, major RAMC, aged 73

TETANUS IN THE MIDDLE EAST
EFFECTS OF ACTIVE IMMUNISATION

Middle East Force

THIS report records the incidence of tetanus during the first 2 years of war in the Middle East, and attempts to assess the part played by active and passive immunisation in the prevention of this disease. Passive immunisation was fully tested in the war of 1914–18, and proved its worth by reducing the incidence of tetanus to under 1 case per 1000 wounded, but the present war is the first occasion on which active immunisation has been submitted to a practical trial.

PRINCIPLES IN TETANUS PREVENTION

Tetanus results from the action of the toxin of *Clostridium tetani* on the motor nerve-cells of the central nervous system. The organism is an anaerobic saprophyte found in the contents of the large intestine of some animals and in soil with which excrement from these is mixed. It forms highly resistant spores. In wounds with dead tissue or blood-clot in their depths, in areas of necrosis produced by foreign bodies, and in regions devitalised by an impoverished blood-supply, implanted spores germinate and multiply. Toxin produced by the vegetative forms finds its way into the body of the host and exercises its specific action on the motor nerve-cells. Since the bacillus lives in dead and not in living tissue, it is not directly subject to the action of the normal phagocytic processes.

Development of tetanus may be avoided by two distinct but complementary measures.

Surgical Treatment.—The potential focus of infection must be extirpated by removal of all dead tissue, blood-clot and foreign bodies from the wound. This helps to prevent gas gangrene as well as tetanus; but surgery alone will not prevent tetanus in every case.

Immunisation.—Any toxin formed before surgery can be carried out, or emanating from small infected pockets or inaccessible portions of dead tissue, must be neutralised by active and passive immunisation.

Active immunity is produced by inoculation with tetanus toxoid, formolised toxoid being used in the British Army. Two injections of 1 c cm. are given at an interval of 6 weeks and a third 6 months or more later. After the first inoculation no antitoxin appears in the circulation but sensitisation, believed to be of the reticulo-endothelial system, develops over about 6 weeks. When the second inoculation is given after this interval, the toxoid stimulates the sensitised reticulo-endothelial system and produces an outpouring of antitoxin into the circulation. In most subjects this reaches a level ranging from 0.1 to 1 unit per c.cm. of serum after an interval of 10–12 days, and thereafter slowly declines. The sensitivity of the reticulo-endothelial system is maintained and apparently enhanced after the second inoculation, so that the third, given 6 months later, is followed by an antitoxin titre which normally rises to from 2 to 10 units per c cm. of serum, and may reach an even higher level.

In an actively immunised subject suffering from a tetanus infected wound the toxin may be regarded as neutralised in two phases. In the early stages the circulating antitoxin inactivates the first quantities of toxin coming from the wound. Meantime the " shadow-factory " in the reticulo-endothelial system is stimulated, and in due course quantities of antitoxin are released into the circulation, ready to reinforce the action of what pre-existing antitoxin remains.

The interval between stimulation of the reticulo-endothelial system and the production of antitoxin has thus an important bearing on the problem of active immunisation. In 1938 an experiment to determine this point was carried out and gave the figures shown in table I. The 5 subjects were some of the RAMC personnel on whom the original experiments in immunisation at the Royal Army Medical College were made[1]; they had been inoculated with varying doses of different preparations.

TABLE I—PRODUCTION OF TETANUS ANTITOXIN IN PREVIOUSLY IMMUNISED SUBJECTS, AFTER A DOSE OF 1 C CM OF TETANUS TOXOID

Recorded in USA units of antitoxin per c cm. of serum

—	Date in 1938	Subjects				
		A	B	C	D	E
Initial antitoxin titre	Sept 9	0.23	0.0065	0.0125	0.05	0.5
Tetanus toxoid 1 c cm. given on Sept 12, subsequent antitoxin titre	13 (1)	0.23	0.0065	0.0125	0.05	0.5
	14 (2)	0.23	0.0065	0.0125	0.05	0.5
	" 15 (3)	0.25	0.010	0.0125	0.055	0.5
	17 (5)	0.85	0.035	0.07	0.55	0.55
	19 (7)	11.00	0.80	2.00	3.50	1.65
	22 (10)	16.00	2.00	3.50	4.50	3.09
	" 26 (14)	16.50	2.00	3.30	4.20	2.70
	Oct 11 (30)	14.00	1.60	3.00	4.00	1.89

Figures in parentheses = number of days after inoculation

It will be noted that antitoxin production begins about the 5th day, and reaches its peak somewhere between the 10th and 14th days. From these data, it has been concluded that in general active immunisation may be expected to afford protection against tetanus in all wounded men who receive adequate surgical treatment. There are, however, possibilities for which provision must be made:

1. The subject may not react to inoculation with toxoid. There is little direct evidence of this, but judging from other processes of immunisation occasional non-reactors are to be expected.

2. Although a subject is immunised, his circulating antitoxin may be small in quantity. There is thus a period of about a week when the barrier of protection is low, and liable to break down.

3. Antitoxin production may be less active in a badly wounded and shocked subject than it is in a normal healthy person.

Passive immunisation consists in introducing into the body a known quantity of preformed antitoxin. This neutralises toxin with which it comes in contact, and consequently becomes exhausted in proportion to the amount of toxin present. If not used up in this way it is slowly destroyed or excreted, so that the quantity remaining a fortnight after inoculation is too small to be of practical value. Repeated inoculations at weekly intervals are necessary to maintain a satisfactory antitoxin level. Antitoxin has no antibacterial properties, and acts solely by rendering toxin innocuous.

ROUTINE PROPHYLAXIS

The following procedures, based on these principles, are now adopted as a routine in the Army.

Each man shortly after enlistment is inoculated with two doses of 1 c cm. of tetanus toxoid at an interval of 6 weeks. After a further interval of at least 6 months a third dose of 1 c cm. is given. Inoculation is on a voluntary basis, but as tetanus toxoid causes little or no reaction (except very rare anaphylactic reactions) it is seldom refused. The percentage inoculated with two doses is over 95% in most units, but up to date a much smaller percentage has received the more recently introduced third dose.

As soon as possible after an injury is inflicted, each wounded man is given a dose of 3000 international units of tetanus antitoxin (ATS). This is intended to cover any gaps in the protection afforded by active immunisation. Unfortunately in the rush of battle conditions this inoculation is occasionally omitted. Should the patient never have been actively immunised, he is given further doses of ATS at weekly intervals.

EXPOSURE TO INFECTION

Little is to be gleaned about the incidence of tetanus from the medical experiences of the BEF in France during 1939–40. There were few casualties until the end of that campaign, and it must be assumed that many of the more severely wounded, about whom nothing is known, were left behind. Bensted[2] gives such information as is available. It was estimated that about 90% of the BEF were inoculated with two doses of tetanus toxoid. In all, 8 cases of tetanus were reported among the unprotected 10% No tetanus developed in the 90% who were actively immunised

In the Middle East it has been possible to obtain records of most of the cases arising, and to study the relationship of the incidence to active and passive immunisation The chances of acquiring tetanus in the Middle East are not comparable to those in France and Flanders The sandy and arid soil of the desert is unsuited for the propagation of anaerobes, though quantities of the desiccated droppings of donkeys, ponies and camels are to be found scattered on the sand near the main tracks An attempt has been made by the examination of samples of soil, and by making cultures from wounds other than those in cases in which tetanus develops, to assess the risk of acquiring tetanus infection in the Middle East

TABLE II—SOIL SAMPLES FROM WHICH TETANUS BACILLI WERE CULTURED

—	Locality	Serological type
1	Dust blown in by sand storm, near Daba	III
2	Agricultural land, Barrani	V
3	Italian Camp 4 km west of Barrani	III
4	Tobruk-Benghazi road, 129 km west of Tobruk	VII
5	Appolonia	II
6	Cultivated land, 10 km west of Barce	I
7	*Barce, hospital* grounds	V
8	Benghazi, roadside	V

Soil samples taken from 91 different spots between Daba and Benghazi (including the Quattara Depression) have been examined for tetanus spores, with positive results in 8 cases (8 8%) In the samples taken between Daba and Tobruk, where the country is mainly desert, tetanus was found only 3 times in 60 samples In the 31 samples taken from the more fertile land west of Tobruk, it was found in 5 Table II shows the locations from which the positive samples were taken, and the serological type of organism recovered All these strains of *Cl tetani* isolated from soil proved to be toxigenic

Despite the relative rarity of tetanus bacilli in soil samples, they are by no means uncommon in wounds A series of 214 wound cultures received from different hospitals has been examined for terminal-spored anaerobes These cultures were taken from wounds of a severe type in which anaerobes were either known or suspected to be present, so that the series is a selected and not a representative one In 63 of these cases gas gangrene was present or supervened An analysis of the terminal-spored anaerobes found in these wounds is given in table III It will be seen that *Cl tetani* was found in 18 (8 4%)

In one hospital, from January, 1941, to July, 1942, wound swabs from a total of 494 cases were examined One or more species of clostridium were found in 66, including 20 terminal-spored anaerobes Of these, 2 were *Cl tetani* (one type III, one type V) The commonness of terminal-spored bacilli in wounds is worthy of note The laboratory often receives from the ward a swab accompanied by a request for an immediate report on the presence of *Cl tetani*, and the surgeon is apt to be aggrieved when told that it will be some days before a definite reply can be given Table III makes the reason obvious it is not possible to give an opinion of any value on morphological appearances alone The laboratory can afford no timely positive assistance in the diagnosis of tetanus, although it may ultimately provide confirmatory evidence Early diagnosis must be based on clinical signs and symptoms

In the period under review, 18 cases of clinical tetanus have been reported in the MEF These include 1 case which was notified from Malta, but it is not known if any other cases have developed there The principal data relating to incidence, prophylaxis, antitoxin therapy, and progress are shown in table IV

United Kingdom, Australian, New Zealand, and Indian troops have been inoculated with tetanus toxoid, but this measure was not adopted for South African troops until comparatively recently German troops were not immunised in the early stages of the campaign when these cases developed, and it is not known whether their practice has since changed Italian troops may or may not have been immunised Captured Italian medical stores included large quantities of a typhoid-paratyphoid vaccine in which tetanus toxoid, later proved to be potent, was embodied, on the other hand the inoculation state of Italian troops was found to be low

In the British and Dominion Forces receiving routine inoculation a consecutive series of casualties included 4 cases of tetanus (2 in Maoris and 2 in Indians, 1 of whom had not been inoculated), and the incidence of the disease was 0 13 per 1000 wounded Among the South Africans during the same period the incidence was 1 6 per 1000 wounded There were 3 cases among an unknown but relatively small number of wounded Germans, 3 in Italians whose inoculation history is uncertain, and 1 in an Eritrean Thus whereas the incidence of tetanus among the actively immunised troops was almost negligible, the number of cases reported in unprotected South African, German and Italian wounded was relatively high Though the total number of cases is small the evidence in favour of active immunisation appears to be fairly definite

TETANUS IN IMMUNISED SUBJECTS

Of the 18 cases of tetanus reported, 5 were in men who had been actively immunised, 4 with two doses, and 1 with three doses One case, in which only a single dose had been given, is included in the non-immunised series. None of these 5 cases received the stipulated dose of 3000 units of ATS as a prophylactic measure after being wounded Of these 5, 2—one a Maori, the other an Indian—recovered

CASE 5 —This Maori received tetanus toxoid on March 11 and April 3, 1940 Wounded in Crete, May 21, 1941 Bullet through left forearm No injury of bone No ATS administered Trismus and neck-rigidity appeared on June 3, 13 days after wounding Not seriously ill No generalised spasms Given 40,000 units ATS intramuscularly and the same intrathecally on June 3 Same dosage repeated on June 4 Gradually improved and recovered *Cl tetani*, type VII, recovered from wound *Chemotherapy* no record

CASE 15 —Indian Only hearsay evidence of this case Said to have developed tetanus after a gunshot wound, and to have recovered Was not reported as tetanus, and when information came to light no further details could be given.

TABLE III—TERMINAL SPORED ANAEROBES FOUND IN CULTURES FROM 214 WAR WOUNDS IN CASES WHICH DID NOT DEVELOP CLINICAL TETANUS

—	A	B	—	A	B
Cl tetani type I	2	1	*Cl cochlearium*	6	3
,, ,, ,, III	3	1	*Cl hastiforme*	2	1
,, ,, ,, IV	1		*Cl capitovale*	4	2
,, ,, ,, V	3	2	*Cl tertium*	20	13
,, ,, ,, VI	1		*Cl sphenoides*	3	2
,, ,, ,, VII	1	3	*Cl tetanomorphum*		1
Cl putrificum	9	8	Unidentified	1	

A=gas gangrene (63 cases) 52 strains of terminal spored anaerobes were isolated

B=wounds not complicated by gas gangrene (151 cases) 65 contained anaerobic bacilli, 37 were terminal spored anaerobes

Of the 5 actively immunised cases 3 were fatal Case 7, the first of these, has been reported in detail by Major R J McGill, the following is an extract of his notes

CASE 7 —Indian Tetanus toxoid, April 25 and June 7, 1941 Not a battle casualty No prophylactic antitoxin administered About Oct 21, while stationed on the Red Sea littoral, cut his hand Dec 2, stiffness of dorsal thoracic muscles and back of neck, 42 days after wounding Dec 4, admitted to hospital Had completely healed wound on left thenar eminence and one on palmar surface of left middle finger, each about $\frac{3}{4}$ in long Moderate risus sardonicus and trismus, the jaws opening $\frac{1}{2}$ in Much stiffness of the back and neck Abdominal muscles rigid, but moved with respiration Paroxysms of opisthotonus regularly every ½ min, lasting about 5 sec, accompanied by clenching of the jaws and spasm of the thoracic and abdominal muscles Limbs unaffected Dec 5, spasms only once a minute Dec 6, spasms every 2 min, much less severe Dec 7, died suddenly

Treatment about 30,000 units ATS before admission to hospital and 80,000 units daily while in hospital

TABLE IV—FINDINGS IN 18 CASES OF TETANUS IN THE MEF

* Not a battle casualty D = death R = recovery pw = prisoner of war

Autopsy left heart comparatively empty, right heart engorged, rupture of one pulmonary cusp, passive congestion of viscera No culture obtained *Chemotherapy* none

This case presents several peculiar features (*a*) The only lesions to which the infection could be attributed were two small, superficial, and completely healed wounds of the hand Unfortunately no cultures or sections were made (*b*) The interval between wounding and the onset of symptoms was 6 weeks, and he died in 5 days (*c*) The symptoms were unusual short spasms lasting about 5 sec at regular intervals of ½ min to begin with, later of about 2 min (*d*) While the tetanic condition was improving, death resulted apparently from the rupture of a pulmonary cusp, a most exceptional and inexplicable event

The possibility of some alternative diagnosis has been carefully considered Rabies can be excluded by the symptomatology and the remaining condition to be considered seems to be some form of poisoning Prof J A. Gunn considers that in spite of the atypical features, tetanus remains the most probable diagnosis in this case Accepting it as one of true tetanus, and the wounds described as the seat of infection, then the focus from which the toxin was evolved was a small one (compare cases 17 and 18) and, as the wounds were healed, the interval between the elaboration of the toxin and the appearance of symptoms must have been considerable According to the patient's documents, he was inoculated with two doses of tetanus toxoid some 6 months before the onset of his illness Had this inoculation resulted in sensitisation of the reticulo-endothelial system, the stimulus afforded by the tetanus toxin elaborated in the wound would, in normal conditions, have led to the production of antitoxin from the 5th day onwards, which, by the time symptoms developed, would have reached a high level (see table I) In cases where toxin production is massive (cases 17 and 18) it is easy to conceive that antitoxin production may be inadequate to neutralise it but in this case there is nothing to suggest excessive toxin formation If inoculation was carried out as recorded—and there is no reason to doubt it—it seems reasonable to conclude that this is one of the rare instances in which the subject has *not* responded to immunisation

CASE 17—A gunner at Malta Tetanus toxoid 1 c cm. Aug 23 and Oct 8, 1940 On June 23, 1942, large wound soft tissues of heel plus comminuted fracture both bones of leg at junction of lower and middle thirds Wounds excised, sutured, put up in plaster No ATS given June 28, 5 days after wounding difficulty in swallowing, trismus, later, neck rigidity *June 29*, stiffness and retraction more pronounced Plaster removed soft tissues necrotic, foul pus in wound, and at site of fracture amputation through fracture Developed respiratory spasm, condition rapidly deteriorated, died

Treatment with ATS June 28, 80,000 units intramuscularly, in two doses June 29, 40,000 units intramuscularly, 200,000 units intravenously *Chemotherapy* no record No culture taken

CASE 18—New Zealander, Maori Tetanus toxoid Jan 12 and Feb 26, 1941, and April 13, 1942 July 14, reported sick, with temperature Later wounded by shrapnel in left arm No ATS given Evacuated via casualty-clearing station to a general hospital Temperature at one stage 103° F July 18, operated on Large foreign body removed from arm Wound dressed with sulphonamide vaseline July 19, given 8 g sulphonamide July 20, transferred to another hospital. Wounds looked clean, arm in sling, noisy and excited July 21, again noisy and irritable Left arm swollen and painful, condition suggestive of cellulitis Wounds explored with sinus forceps, no frank pus July 22, attempted to hit anyone who came near him Foments applied to left arm July 23, more excited, got out of bed and tried to hit another patient Complained of pain in chest Slight twitching of the arm noticed T 102° F July 24, mild tonic spasms began which increased during day At 7 PM temperature had risen to 107° Died at 7 45

Treatment ATS on July 24 at 4 30 PM, 60,000 units partly intravenously partly intramuscularly, at 6 PM 90,000 units intramuscularly

Autopsy left forearm and arm greatly swollen, two large wounds on posterolateral aspect of left arm with superficial healing; spiral fracture of middle third of humerus, and all deep muscles showed extensive necrosis, almost colliquative, no actual pus or gas present, liver and kidneys showed toxic changes Portions of muscle from the upper and lower ends of triceps, and the deep surface of the trapezius, and a portion of bone marrow from the humerus all yielded a growth of *Cl tetani*, type III. Other anaerobes were present, but have not yet been identified

Cases 17 and 18, apparent failures of active immunisation, fall into a different category from case 7 Both have in common the presence of a mass of necrotic tissue, in which there was ample opportunity for the tetanus bacillus to flourish freely and to produce large quantities of toxin In neither was there evidence of an active pyogenic process to draw attention to the fact that the wound required immediate surgical intervention In case 17 primary suture was carried out and progress was normal until tetanic symptoms appeared Removal of the plaster showed the presence of necrosis of the soft tissues with foul pus In case 18 the peculiar mental reactions of the patient made adequate examination difficult Even so, exploration of the wound with sinus forceps failed to reveal frank pus on July 21 and at autopsy on July 24, though the arm was found to be much swollen with extensive *necrosis* of all the deep muscles, there was neither pus nor gas In both cases then, conditions were ideal for the massive production of tetanus toxin, and *it is reasonable to* assume that it was manufactured on a scale which far outpaced the antitoxin production of the patient's reticulo-endothelial system

The interval which elapsed between wounding and the appearance of symptoms in these two cases is significant Case 17 had two doses of toxoid 20 months before he was wounded If his reaction was normal, he probably had an average but not a large amount of free antitoxin in his circulation, and a shadow-factory ready to come into production when stimulated However, the facilities for toxin production in the wound were such that sufficient was elaborated not only to overcome the barrier of the free antitoxin, but to result in the onset of symptoms on the 5th day with a fatal termination 36 hours later (i e before his defence mechanism could come into action) Case 18 received two doses of tetanus toxoid at the beginning of 1941, and a third dose in April, 1942, 3 months before he was wounded It is therefore to be expected that the level of his circulating antitoxin would be high, and that the response of his defence mechanism would be good There can be little doubt that such was the case Despite the fact that tetanus infection was widespread throughout the left upper arm and shoulder, so that toxin production must have been on a very extensive scale, symptoms did not appear until the 9th day The most probable explanation is that the antitoxin barrier was so high that for a time it sufficed to stem even this exceptionally intense invasion Ultimately, however, a stage was reached when toxin dominated and symptoms ensued

TETANUS IN NON-IMMUNISED SUBJECTS

Of the 18 cases, 13 were in the non-immunised series Of these 13, one received a single dose of 1 c cm of tetanus toxoid 3½ months before he was wounded, 3 others were Italian prisoners and 1 an Eritrean prisoner, regarding whose inoculation history nothing is known, 6 cases were fatal, so that the mortality rate was less than 50%

Information about the interval which elapsed between wounding and the appearance of symptoms is lacking in 2 of the fatal cases The average for the remaining 4 is 16 days, 3 of these received prophylactic ATS, 1 did not; the interval in the last was 17 days In the 7 non-fatal cases, the average interval was 14 9 days None of these seems to have received any prophylactic ATS, though it was possibly given without being recorded The numbers are too small to be significant, but the general tendency towards a long incubation period is interesting It cannot be attributed to antitoxin treatment, but may in some way be related to effective surgical treatment resulting in the removal of all but the most trivial foci of infection

CASE 1—Italian prisoner History of active immunisation unknown Date of wounding unknown Small wound 1 5 cm in diameter above right knee No muscle involvement No record of prophylactic ATS Jan 13, 1941, onset of generalised tetanic spasms which quickly became violent, died 5½ hours after onset

Treatment ATS 50,000 units intramuscularly *Cl tetani*, type v, cultured from wound *Chemotherapy* no record

CASE 2—Italian prisoner History of active immunisation unknown Jan 3, 1941, shrapnel wounds of outer aspect of left thigh, involving muscle Dressed with sulphapyridine and eusol No record of prophylactic ATS Jan 15, stiffness of jaw, neck and back, 12 days after wounding Jan 19, generalised spasm Jan 21, last generalised spasm Recovered

Treatment with ATS received 117,000 units, including Jan. 18, 40,000 units intramuscularly, 4000 units intrathecally, Jan 19, 15,000 units, Jan 26, 20,000 units, Feb 3, 20,000 units, all intramuscularly *Cl tetani*, type III, isolated from wound *Chemotherapy* only as noted

CASE 3—Italian prisoner No record of this case, other than a culture with a serial number, and a statement that the patient had died with the symptoms of tetanus Attempts to obtain further information unavailing *Cl tetani*, type I, grown from culture

CASE 4—Eritrean prisoner No definite history of immunisation, unlikely Wounded in right thigh. mitted hospital 28 days later with healing ulcer 6 cm and small sinus going down to muscle Had flexion defo and was manipulated under an anæsthetic, 3 days developed stiffness of jaw and had a mild convulsion ATS (dose not stated) and recovered without further toms Organisms morphologically resembling *Cl* cultured from sinus No other details available *Chemotherapy* no record

CASE 6—German prisoner Not actively immunised. Wounded probably June 16, 1941 Given ATS 3000 units. Admitted base hospital June 21 with infected foul smelling sucking wound over right shoulder Slow progress July 9, tonic spasms of left thigh muscles 23 days after wounding July 10, worse, with severe clonic spasm of great severity lasting 2–3 sec Attributed to salt loss and treated accordingly July 11, much the same July 14, still cramps, left knee now completely flexed Aug 1, leg less flexed, now could be extended almost completely Possibility of symptoms being due to upper motor neuron lesions considered. Aug 10, general condition much improved Aug 30, further operation on thorax Large foreign body removed from posterior wall Sept 6, return of cramp like pains in legs Thigh muscles in spasms Pain behind angles of jaw Sept 8, definite trismus, 90,000 units ATS given (route not specified) Sept 9, died *Cl tetani*, type v, recovered from wound *Chemotherapy* sulphapyridine 1 g three times daily from June 27 for an unspecified period

CASE 8—South African Not actively immunised Wounded Nov 23, 1941 Multiple gunshot wounds, thigh and genitalia No prophylactic ATS Trismus appeared Dec 8, 15 days after wounding Progressed until Dec 15, masseters, neck muscles, back muscles and rectus abdominis all spastic No tetanic convulsions Improvement started Dec 17 Recovered

Treatment with ATS received a total of 400,000 units, including Dec 11, 3000 units subcutaneously and 40,000 units intramuscularly, Dec 12, 200,000 units intravenously, Dec 14, 20,000 units intramuscularly *Cl. tetani*, type v, isolated from culture *Chemotherapy* sulphanilamide 4 g on Nov 24, 1 g on Nov 30 and Dec. 1 Sulphapyridine 1 g on Dec 10

CASE 9—German prisoner Not actively immunised Wounded buttock Nov 24, 3000 units ATS given on Nov 26 Symptoms appeared Dec 10, after interval of 16 days Trismus going on to generalised spasm, 50,000 units ATS given on Dec 10 Died Dec 11 No culture taken *Chemotherapy* no record

CASE 10—German prisoner Not actively immunised Wounded Nov 29 in right leg half-way between knee and ankle *No record of prophylactic ATS* Nov 31, leg amputated Dec 16, symptoms of tetanus appeared, after interval of 17 days, 60,000 units ATS given Dec 20, died *Cl tetani*, type v, isolated from culture *Chemotherapy* no record

CASE 11—Indian Not actively immunised Dec 6, 1941, bomb wound right ankle No ATS given Dec 13, foot amputated Dec 18, trismus developed, 12 days after wounding ATS 117,000 units given Dec 24, symptoms passed off No culture taken *Chemotherapy* no record

CASE 12—South African Not actively immunised. Dec 12, 1941, gunshot wound of buttock with moderate laceration of muscle Dec 13, superficial *excision* Dec 19 (a week after wounding), ATS 3000 units Dec 20, slight spasms of affected limbs, 8 days after wounding Dec 22, wide excision and drainage Gradually developed generalised spasms and opisthotonus Dec 23, died

Treatment with ATS Dec 21, 80,000 units intramuscularly and intravenously, Dec 22, 80,000 units intravenously, Dec 23, 80,000 units intravenously No culture taken *Chemotherapy* sulphonamide powder locally

CASE 13—South African Not actively immunised Nov 27, 1941, wounded in right wrist, shoulder and both legs No record of prophylactic ATS Dec 24, developed stiffness of ankle and recurring spasm of leg muscles *Dec 28*, typical tetanic spasm lasting 3½ min, with risus sardonicus and opisthotonus Two further shorter spasms Local spasms gradually disappeared Recovered

Treatment with ATS Dec 28, 60,000 units, intravenously, Dec. 29, 200,000 units intravenously. *Cl tetani*, type VII. isolated in culture *Chemotherapy* no record

CASE 14 —South African Not actively immunised Jan. 18, 1942, gunshot wound inner side left thigh No prophylactic ATS Jan 18 and 26 surgical intervention Feb 14, 27 days after wounding, onset of tetanic spasms, which became generalised

Treatment Feb 15 and 18, 200,000 units ATS intravenously on each day Total amount given, 600,000 units Steady progress to recovery No material submitted for culture *Chemotherapy* prophylactic sulphonamide "by mouth and powder into the wound" No further details

CASE 16 —South African Tetanus toxoid, 1 c cm March 11, 1942 June 28, bomb wound left calf, much destruction of muscle No record of prophylactic ATS July 1, after debridement wound treated with sulphanilamide powder July 6, 8 days after wounding, developed recurring spasms of calf every 15–20 min, trismus, and risus sardonicus Opisthotonus and violent spasms of back after ATS Wound curetted and again treated with sulphanilamide powder Tetanic spasms continued but became less severe, all symptoms finally disappearing on July 15

Treatment with ATS July 6, 15,000 units intrathecally, 15,000 units intramuscularly, and 12,000 units intravenously, later 60,000 units intravenously, and tetanus toxoid 1 c cm July 7–16, 420 000 units ATS intravenously *Chemotherapy* local treatment as above From July 7, course of sulphapyridine given, exact dosage not recorded *Cl tetani*, toxigenic strain, grown from wound This appears to be a new type

In case 16 symptoms developed within 8 days of wounding Since a single dose of toxoid produced no circulating antitoxin, the dose given can have had no influence in preventing the onset of the disease There is nothing to be gained by giving tetanus toxoid to a patient in whom symptoms of tetanus have already appeared, the toxin from the wound should already have provided the stimulus

As far as these cases are concerned, the effect of chemotherapy as a prophylactic measure can be dismissed in a sentence In none of them is there any record that the standard course of treatment, or in fact any adequate quantity of the sulphonamide drugs, has been given; so that no conclusions for or against their use can be drawn

DISCUSSION

The evidence presented in this report indicates the value of active immunisation against tetanus, but the fact that 5 cases developed in inoculated men shows that this measure has its limitations A study of these 5 cases brings out two possible causes of failure The first—lack of response to immunisation—may possibly be overcome by the third dose of toxoid which is now being given In addition to this, the more lightly infected cases are likely to receive adequate passive protection from the single dose of antitoxin which is recommended The second cause of failure—massive and fulminating infection—introduces another factor In cases 17 and 18 immunisation may or may not have been successful, but in both there is evidence to suggest that the focus of infection was so extensive that toxin was formed rapidly and in sufficient quantity to outpace the antitoxin production of the defence mechanism It seems probable, particularly in case 18, that the outcome would have been the same irrespective of the state of immunity of the patient

The lesson to be drawn from these 2 cases is clear The protection afforded by active immunisation has its "ceiling" It appears capable of inactivating toxin from a wound which has received adequate surgical attention and from which the bulk of necrotic tissue has been removed It is *not* capable of neutralising the massive quantities of toxin formed in extensive areas of necrotic tissue Careful surgical treatment with removal of all dead tissue is therefore an important factor in preventing the onset of tetanus This is a point which is liable to be overlooked from the theoretical standpoint, though in practice it has not been neglected, since it forms part of the routine treatment of all wounds as a preventive against the more common condition, gas gangrene

Case 17 shows that the closed plaster technique is not without its dangers in the exceptional case In this patient the presence of a mass of necrotic tissue was unsuspected until symptoms supervened, when it was too late for him to benefit from its removal This report relates to a country in which the risk of tetanus is relatively low It still remains to be seen if active immunisation is capable of combating the heavy infections likely to be incurred in such places as France or Flanders

SUMMARY

The chances of becoming infected with tetanus in the Middle East, and particularly in the Western Desert, are much less than those in France and Flanders Nevertheless, they are greater than might be expected, as can be seen from the presence of tetanus spores in soil samples, and tetanus bacilli in wounds

In the first two years of war in the Middle East 18 cases of tetanus were reported

The distribution of cases among inoculated and uninoculated troops affords evidence of the value of active immunisation Nevertheless 5 cases, 3 of them fatal, developed in inoculated men The protection afforded by active immunisation therefore has its limitations

In one of these fatal cases, there seems to have been little or no response to immunisation with two doses of toxoid This emphasises the necessity for giving a third dose of toxoid, and for heightening the barrier by giving a dose of antitoxin after the man is wounded

In the other 2 fatal inoculated cases failure can be attributed to overwhelming infection resulting from the presence of masses of necrotic tissue in the wound This indicates that the immunity afforded by inoculation with tetanus toxoid has its "ceiling," and that adequate surgery is an essential complementary part of the preventive treatment of tetanus

We wish to thank the various surgeons and pathologists in the Middle East Force who have supplied data, and provided cultures from the wounds, and Mr A T Glenny of the Wellcome Physiological Research Laboratories who carried out the titrations in the experiments recorded in table I

LONG INCUBATION PERIOD OF SYPHILIS AND AN ELUSIVE PRIMARY SORE

MARY MICHAEL-SHAW, M B LOND
DIRECTOR, V D DEPARTMENT ROYAL FREE HOSPITAL
MEDICAL OFFICER, V D DEPARTMENT, MOTHERS' HOSPITAL

THE following two cases seem worth reporting now when many contacts of patients proved to be suffering from venereal disease are presenting themselves for examination

CASE 1 —A married woman, aged 24, came for examination on Jan 29, 1942, having heard from her husband that he was in a military hospital suffering from early primary syphilis (the latter fact was confirmed) Intercourse had taken place 6 days previously and the husband had worn a sheath. The only clinical finding was that glands were palpable in the groins, but the patient was of the thin type in whom these glands can not uncommonly be felt Wassermann and Kahn tests were negative as were smears and cultures from urethra and cervix for gonococci The patient was asked to return in 4 weeks' time or before if she noticed anything wrong

She came back on Feb 26 Again there was no clinical evidence of infection and Wassermann and Kahn tests were again negative Similar advice was given and the patient returned on April 1, and again on April 23, with the same negative results By the time the Wassermann of the 23rd was reported on she had been under observation for nearly 13 weeks, and in view of this and the history of her husband having worn a sheath she was discharged

Three weeks later, on May 20, she returned complaining of "spots" on the vulva Two small sores were found on the left labium majus, unfortunately no scraping was taken but Wassermann and Kahn tests were returned positive and these were repeated after an initial arsenic injection and again were positive There had been no exposure to infection since marital intercourse on Jan 23, the patient was coöperative and intelligent, she had originally been informed as to early signs Even if these sores appeared directly after her last examination one must conclude that the incubation period was some 90–110 days

CASE 2 —A married woman, aged 28, came for examination on Aug 8, 1942, because her husband had been admitted to a military hospital on Aug 4 with early primary syphilis The of the wound with sinus forceps failed to reveal frank pus on July 21, and at autopsy on July 24, though the arm was found to be much swollen with extensive necrosis of all the deep muscles, there was neither pus nor gas In both cases, then, conditions were ideal for the massive production of tetanus toxin, and it is reasonable to assume that it was manufactured on a scale which far outpaced the antitoxin production of the patient's reticulo-endothelial system

The interval which elapsed between wounding and the appearance of symptoms in these two cases is significant. Case 17 had two doses of toxoid 20 months before he was wounded If his reaction was normal, he probably had an average but not a large amount of free antitoxin in his circulation, and a shadow-factory ready to come into production when stimulated However, the facilities for toxin production in the wound were such that sufficient was elaborated not only to overcome the barrier of the free antitoxin, but to result in the onset of symptoms on the 5th day with a fatal termination 36 hours later (i e before his defence mechanism could come into action) Case 18 received two doses of tetanus toxoid at the beginning of 1941, and a third dose in April, 1942, 3 months before he was wounded It is therefore to be expected that the level of his circulating antitoxin would be high, and that the response of his defence mechanism would be good There can be little doubt that such was the case Despite the fact that tetanus infection was widespread throughout the left upper arm and shoulder, so that toxin production must have been on a very extensive scale, symptoms did not appear until the 9th day The most probable explanation is that the antitoxin barrier was so high that for a time it sufficed to stem even this exceptionally intense invasion Ultimately, however, a stage was reached when toxin dominated and symptoms ensued

TETANUS IN NON-IMMUNISED SUBJECTS

Of the 18 cases, 13 were in the non-immunised series Of these 13, one received a single dose of 1 c cm of tetanus toxoid 3½ months before he was wounded, 3 others were Italian prisoners and 1 an Eritrean prisoner, regarding whose inoculation history nothing is known, 6 cases were fatal, so that the mortality rate was less than 50%

Information about the interval which elapsed between wounding and the appearance of symptoms is lacking in 2 of the fatal cases The average for the remaining 4 is 16 days, 3 of these received prophylactic ATS, 1 did not, the interval in the last was 17 days In the 7 non-fatal cases, the average interval was 14 9 days None of these seems to have received any prophylactic ATS, though it was possibly given without being recorded The numbers are too small to be significant, but the general tendency towards a long incubation period is interesting It cannot be attributed to antitoxin treatment, but may in some way be related to effective surgical treatment resulting in the removal of all but the most trivial foci of infection

CASE 1 —Italian prisoner History of active immunisation unknown Date of wounding unknown Small wound 1 5 cm in diameter above right knee No muscle involvement No record of prophylactic ATS Jan 13, 1941, onset of generalised tetanic spasms which quickly became violent, died 5½ hours after onset

Treatment ATS 50,000 units intramuscularly *Cl tetani,* type v, cultured from wound *Chemotherapy* no record

CASE 2 —Italian prisoner History of active immunisation unknown Jan 3, 1941, shrapnel wounds of outer aspect of left thigh, involving muscle Dressed with sulphapyridine and eusol *No record of prophylactic ATS* Jan 15, stiffness of jaw, neck and back, 12 days after wounding Jan 19, generalised spasm Jan 21, last generalised spasm Recovered

Treatment with ATS received 117,000 units, including Jan. 18, 40,000 units intramuscularly, 4000 units intrathecally, Jan 19, 15,000 units, Jan 26, 20,000 units, Feb 3, 20,000 units, all intramuscularly *Cl tetani,* type III, isolated from wound *Chemotherapy* only as noted

CASE 3 —Italian prisoner No record of this case, other than a culture with a serial number, and a statement that the patient had died with the symptoms of tetanus Attempts to obtain further information unavailing *Cl tetani,* type I, grown from culture

CASE 4 —Eritrean prisoner No definite history of ac immunisation, unlikely Wounded in right thigh Ad mitted hospital 28 days later with healing ulcer 6 cm acro and small sinus going down to muscle Had flexion deform and was manipulated under an anæsthetic, 3 days lat developed stiffness of jaw and had a mild convulsion Give ATS (dose not stated) and recovered without further symp toms Organisms morphologically resembling *Cl tetan* cultured from sinus No other details available *Chemo therapy* no record

CASE 6 —German prisoner Not actively immunise Wounded probably June 16, 1941 Given ATS 3000 unit Admitted base hospital June 21 with infected foul smellin sucking wound over right shoulder Slow progress July tonic spasms of left thigh muscles 23 days after woundin July 10, worse, with severe clonic spasm of great severit lasting 2–3 sec *Attributed to salt loss and treated* accord ingly July 11, much the same July 14, still cramps, le knee now completely flexed Aug 1, leg less flexed, no could be extended almost completely Possibility of symp toms being due to upper motor neuron lesions considere Aug 10, general condition much improved Aug 30, furthe operation on thorax Large foreign body removed fro posterior wall Sept 6, return of cramp like pains in leg Thigh muscles in spasms Pain behind angles of jaw Sept definite trismus, 90,000 units ATS given (route not specified Sept 9, died *Cl tetani,* type v, recovered from woun *Chemotherapy* sulphapyridine 1 g three times daily fro June 27 for an unspecified period

CASE 8 —South African Not actively immunised Wounded Nov 23, 1941 Multiple gunshot wounds, thigh and genitalia No prophylactic ATS Trismus appeared Dec 8, 15 days after wounding Progressed until Dec 15, masseters, neck muscles, back muscles and rectus abdominis all spastic No tetanic convulsions Improvement started Dec 17 Recovered

Treatment with ATS received a total of 400,000 units, including Dec 11, 3000 units subcutaneously and 40,000 units intramuscularly, Dec 12, 200,000 units intravenously, Dec 14, 20,000 units intramuscularly *Cl tetani,* type v, isolated from culture *Chemotherapy* sulphanilamide 4 g on Nov 24, 1 g on Nov 30 and Dec 1 Sulphapyridine 1 g on Dec 10

CASE 9 —German prisoner Not actively immunised Wounded buttock Nov 24, 3000 units ATS given on Nov. 26 Symptoms appeared Dec 10, after interval of 16 days Trismus going on to generalised spasm, 50,000 units ATS given on Dec 10 Died Dec 11 No culture taken *Chemotherapy no record*

CASE 10 —German prisoner Not actively immunised Wounded Nov 29 in right leg half way between knee and ankle No record of prophylactic ATS Nov 31, leg amputated Dec 16, symptoms of tetanus appeared, after interval of 17 days, 60,000 units ATS given Dec 20, died *Cl tetani,* type v, isolated from culture *Chemotherapy* no record

CASE 11 —Indian Not actively immunised Dec 6, 1941, bomb wound right ankle No ATS given Dec 13, foot amputated Dec 18, trismus developed, 12 days after wounding ATS 117,000 units given Dec 24, symptoms passed off No culture taken *Chemotherapy* no record

CASE 12 —South African Not actively immunised Dec 12, 1941, gunshot wound of buttock with moderate laceration of muscle Dec 13, superficial excision Dec 19 (a week after wounding), ATS 3000 units Dec 20, slight spasms of affected limbs, 8 days after wounding Dec 22, wide excision and drainage Gradually developed generalised spasms and opisthotonus Dec 23, died

Treatment with ATS Dec 21, 80,000 units intramuscularly and intravenously, Dec 22, 80,000 units intravenously, Dec 23, 80,000 units intravenously No culture taken *Chemotherapy* sulphonamide powder locally

CASE 13 —South African Not actively immunised Nov 27, 1941, wounded in right wrist, shoulder and both legs No record of prophylactic ATS Dec 24, developed stiffness of ankle and recurring spasm of leg muscles Dec 28, typical tetanic spasm lasting 3½ min, with risus sardonicus and opisthotonus Two further shorter spasms Local spasms gradually disappeared Recovered

Treatment with ATS Dec 28, 60,000 units, intravenously, Dec 29, 200,000 units intravenously *Cl tetani,* type VII, isolated in culture *Chemotherapy* no record is compared directly with that of 40 mg of sulphanilamide applied locally an hour after infection, as in expt 3, table III, it will be seen that proflavine is much more active than sulphanilamide in preventing the development of *Cl welchii* infection Expt 4, table III, compares the action of proflavine and sulphathiazole at 1½ hours after infection and again shows the superiority of proflavine In the latter experiment combined treatment with full doses of proflavine and sulphathiazole appears to be of less value than treatment with either drug alone

Penicillin —A sample of penicillin was kindly supplied by Dr C G Pope of the Wellcome Physiological Research Laboratories This preparation, PN183, consists of a solution of the barium salt and contains 170 Oxford units per c cm The dose employed in mice was 0 2 c cm, equivalent to 34 Oxford units This dose was sufficient to save all the mice in three experiments (table I) Expt 2, table III, shows that penicillin is also of great value in preventing death from *Cl welchii* when it is administered after a delay of an hour, and is also of some value in delaying death when it is administered 3 and 6 hours after infection The superiority of penicillin to proflavine in local treatment is shown in expt 5, table III, where the effect of immediate and delayed administration of the two drugs is directly compared From these results it appears that penicillin is of greater value than proflavine or the sulphonamides in preventing the development of *Cl welchii* infection

Gramicidin —A sample of tyrothricin, the preparation used in these experiments, was supplied to us by the Medical Research Council through the courtesy of Sir Henry Dale It is a water insoluble, alcohol soluble, fraction of the bactericidal substance originally prepared by Dubos (1939) from a soil bacterium It contains both gramicidin, active against gram-positive bacteria, and tyrocidine, which is also active against gram-negative organisms (Hotchkiss and Dubos 1940) In our hands this preparation inhibits the growth cultures of *Cl welchii*, *Cl septique* and *Cl œdematiens* in a concentration of 1 0 µg per c cm and has occasionally prevented the growth of *Cl welchii* in a concentration of 0 1 µg per c cm

The action of tyrothricin on the development of *Cl welchii* in mice was tested by injecting a suspension in saline, immediately after infection The results were discouraging in that most of the treated mice died within 24 hours and none survived to the third day even with doses of 2 µg It appears therefore that although tyrothricin has a powerful bacteriostatic action on *Cl welchii* in vitro it is not likely to give commensurate results clinically in its present form

TABLE II—COMPARATIVE EFFECTS ON *Cl welchii* INFECTION IN MICE OF ZINC PEROXIDE AND SULPHANILAMIDE, HYPEROL AND ZINC OXIDE, AND OF PROFLAVINE AND SULPHANILAMIDE, ADMINISTERED LOCALLY AT THE TIME OF INFECTION

Expt	Drug	Mice	Mice dying on day			Survived 3 days	Av no of days survived
			1	2	3		
1	Zinc peroxide 20 mg	12	1	3	0	8	2 3
	Sulphanilamide 40 mg	12	0	2	2	8	2 5
2	Zinc peroxide 10 mg	12	2	2	0	8	2 2
	Hyperol 100 mg	12	6	1	0	5	1 3
3	Zinc peroxide 20 mg	6	3	3		0	0 5
	Zinc oxide 20 mg	6	3	3		0	0 5
4	Proflavine 0 5 mg	12	0	1	0	11	2 8
	Sulphanilamide 40 mg	12	3	0	1	8	2 2

In each experiment a control group of untreated mice, equal in number to the treated groups, all died within 24 hours

TABLE III—EFFECT ON *Cl welchii* INFECTION IN MICE OF DELAYED LOCAL ADMINISTRATION OF PROFLAVINE AND PENICILLIN AND COMPARATIVE EFFECTS OF DELAY ON PREVENTIVE ACTION OF PROFLAVINE, SULPHANILAMIDE, SULPHATHIAZOLE AND ZINC PEROXIDE, AND OF PROFLAVINE AND PENICILLIN

Expt	*Drug*	Treatment given after hours	Mice	Mice dying on day			Survived 3 days	Av no of days survived
				1	2	3		
1	Proflavine, 1·0 mg	0	6	2	0	0	4	2 0
		1	6	2	0	1	3	1 8

		2	12	1	0	0	11	2 8

In each experiment a control group of untreated mice, equal in number to the treated groups, all died within 24 hours

DISCUSSION

In trying to assess the true preventive and therapeutic values of the remedies reported on here an endeavour has been made to produce an experimental infection comparable to the natural infection Human gas gangrene develops when limb muscles have been severely lacerated and simultaneously contaminated with soil bacteria In the natural disease the clostridia are in the resting (sporing) stage and thus when the wound is infected there can be none of their own bacterial aggressin (toxin) present The inciting agent was shown by Bullock (Gye) and Cramer (1919) in the last war to be in all probability the calcium ion They showed that pathogenic clostridia washed free of all toxin were no longer capable of inciting an infection but could do so if a small amount of calcium chloride was injected along with them

We have therefore induced our experimental infection in mice with toxin-free clostridia, using calcium chloride as the aggressin, the infective dose being so standardised that about 100 lethal (infecting) doses were used as the test inoculum This dose produces at first a purely local infection which in the course of 3 or 4 hours becomes generalised as shown by the presence of clostridia in the blood Thus we have a local and general infection on which the remedies can be tested, and these present different problems

Experimental work on the action of zinc peroxide on *Cl welchii* infection has given somewhat conflicting results Reed and Orr (1942) found that in *Cl welchii* infection in guineapigs the local application of zinc peroxide was a powerful prophylactic and that it was only slightly less effective than sulphathiazole in an established infection On the other hand, Bliss, Long and Smith (1941) found that zinc peroxide administered locally had no effect on *Cl welchii* infection in mice but was effective against infections with *Cl septique*, *Cl œdematiens* and *Cl tetani* Our results show that zinc peroxide is an effective prophylactic against *Cl welchii* infection, but is without action once the organisms get into the tissues This result would be expected if zinc peroxide acted through its oxygenating action, which can have a considerable effect as has been shown in our experiments with hyperol, because this would be more effective on unprotected bacteria than on bacteria protected from oxidative changes by the tissue fluids The tissues may also act as a deterrent if, as Garrod (1940) has suggested and we have shown here, the zinc ion plays a large part in its antibacterial action

Hawking (1941) has shown that proflavine will prevent infection of wounds in guineapigs by anaerobes subsequently inserted On reopening such wounds on the third day he found fairly healthy tissues and only small numbers of bacilli He however decided that the usefulness of proflavine was limited in view of the mediocre results obtained with acridine compounds in patient had douched that morning and there were no clinical findings except for palpable glands in the groin. All pathological tests were negative for gonorrhœa and syphilis and the patient returned in 5 days to hear these results and for further examination. She was then found to have a thin frothy discharge due to *Trichomonas vaginalis*; smears, cultures, Wassermann and Kahn were again negative. Antiseptics were withheld and only palliative treatment for the trichomonas infection advised. Further examinations and blood tests were carried out Aug. 20 and Sept. 10; *no clinical* evidence of syphilis was found and Wassermann and Kahn tests were again negative.

The patient returned on Oct. 15. Externally there was no *sign of infection*, and a speculum was passed to examine vagina and cervix. After swabbing the cervix was clear and uninflamed but a minute cream coloured spot at one edge of the speculum was seen. The first thought was that a wisp of cotton-wool had been left behind after swabbing, but on slightly withdrawing the Ferguson speculum the "wisp" became one corner of a somewhat triangular ulcer high on the lateral wall of the left fornix. The speculum was removed but digital examination only with difficulty detected the ulcer and a satisfactory view was only obtained by using a bivalve speculum. Clinically the ulcer was syphilitic; a scraping showed *Spirochæta pallida* and blood tests were returned positive.

These two cases illustrate the ease with which early syphilis can go undetected even when being searched for. In the first the difficulty arose from the long incubation period coupled with the minor fact of a sheath having been used during intercourse; in the second from the unusual position of the primary sore in the lateral fornix.

ZINC PEROXIDE, PROFLAVINE AND PENICILLIN IN EXPERIMENTAL CL. WELCHII INFECTIONS

JAMES McINTOSH
M.D., LL.D. ABERD
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON

F. R. SELBIE
M.D. ABERD
ASSISTANT PATHOLOGIST AT THE BLAND SUTTON INSTITUTE

(From the laboratory at the Bland Sutton Institute of Pathology, Middlesex Hospital, and the Central Pathology Laboratory, EMS, Sector V)

EVEN with the most up-to-date treatment (surgery, serum therapy and chemotherapy) gas gangrene remains a serious complication of battle and air-raid wounds on account of its high fatality (30%–50%). The rapidity with which the disease can develop in torn and lacerated muscles makes preventive treatment difficult, and this is particularly the case with *Clostridium welchii*, the commonest cause of gas gangrene in Western Europe. We are now trying to find out the most suitable chemotherapeutic and specific treatment immediately after wounding. We have already shown that the sulphonamides are of value in preventing the development of gas gangrene in mice when administered locally in large quantities and soon after infection (McIntosh and Selbie 1941). Several publications, notably those of Hawking (1941) and Reed and Orr (1941) have supported our findings. Other further studies include investigations on the action of zinc peroxide, proflavine, penicillin and gramicidin on *Cl. welchii* infection.

MATERIAL AND METHODS

The strain of *Cl. welchii* and the methods used were the same as in our previous experiments except that bacterial suspensions for infection were prepared from 18-hour anaerobic cultures in 4% Difco proteose-peptone in distilled water. With this medium it was possible to obtain highly virulent cultures with much greater regularity than with Robinson's meat broth. Throughout the experiments we found that the intramuscular injection in the right thigh of 0.1 c.cm. of a washed suspension containing 2000 or 4000 million *Cl. welchii* and 0.1 c.cm. of 5% calcium chloride was sufficient to kill all untreated mice within 24 hours. This dose has usually been equivalent to at least 100 lethal doses and is therefore a severe test of preventive and therapeutic measures. It will become evident, however, that there were considerable variations in the severity of the infection, in that there was a variable response treatment with the same drug. The substances to tested for their prophylactic or therapeutic effect injected into the right thigh at the site of immediately after or at varying intervals after

EXPERIMENTAL RESULTS

The results are presented in a series of tables in which the mortality for only 3 days is considered since mice surviving that time usually survive indefinitely. The average number of days survived, shown in each table, is obtained by dividing the total number of whole days survived in each group of mice by the number of mice in the group. The sum of a number of experiments with sulphanilamide, done during the same period, is included in table I for comparison.

TABLE I—EFFECT ON *Cl. welchii* INFECTION IN MICE OF SULPHANILAMIDE, ZINC PEROXIDE, PROFLAVINE, AND PENICILLIN, ADMINISTERED LOCALLY AT TIME OF INFECTION

Drug	No. of expts	Mice	Mice dying on day			Survived 3 days and %	Av. no. of days survived
			1	2	3		
Sulphanilamide 40 mg.	7	60	11	13	5	31 (52)	1.9
Zinc peroxide 20 mg.	4	36	7	7	4	18 (50)	1.9
Proflavine 0.5 mg.	6	48	7	3	1	37 (77)	2.4
Penicillin 34 units	3	24	0	0	0	24 (100)	3.0

A control group of untreated mice in each experiment all died within 24 hours.

Zinc peroxide.—The preparation used in these experiments contains about 20% zinc peroxide. It will be seen from table I that 20 mg. of zinc peroxide is as effective as 40 mg. of sulphanilamide when administered locally at the time of infection. This result is confirmed by expt. 1, table II, where the two drugs are compared directly. In expts. 2 and 3, table II, the prophylactic action of zinc peroxide is compared with 'Hyperol' (Richter), a solid preparation of hydrogen peroxide and urea yielding 35% hydrogen peroxide by weight, and with zinc oxide. These experiments show that 10 mg. of zinc peroxide is of more value than 100 mg. of hyperol and that zinc oxide is as effective as zinc peroxide. It seems therefore that, although the oxygenating chemicals may be of some value in preventing the development of *Cl. welchii* infection, the zinc ion probably plays a large part in the bacteriostatic action of zinc peroxide. Tests for the effect of delay on the local application of zinc peroxide and hyperol show that an hour's delay in administration totally annuls their preventive effect, as is shown for zinc peroxide in expt. 3, table III. It can be concluded that although zinc peroxide has a powerful bacteriostatic action on *Cl. welchii* it is unable to exert this action once the organisms have invaded the tissues.

Proflavine.—The usual dose of proflavine used was 0.1 c.cm. of a 0.5% solution in distilled water, equivalent to 0.5 mg. of the drug. This dose is ⅙ of the LD 50 dose as determined by Rubbo, Albert and Maxwell (1942) and is probably less than half the maximum tolerated dose. It will be seen from table I, which summarises a number of experiments, that 0.5 mg. of proflavine is of greater value than 40 mg. of sulphanilamide in preventing the development of *Cl. welchii* infection when it is applied locally at the time of infection. The superiority of proflavine to sulphanilamide in this respect is borne out by expt. 4 in table II, where their prophylactic action is compared directly. A further test is required to determine whether proflavine, like the sulphonamides, can exert its bacteriostatic action on *Cl. welchii* which have invaded the tissues. Such a test is shown in expt. 1, table III; when the local administration of proflavine is delayed for an hour its preventive value is only slightly diminished, but after 3 or more hours, when the organisms have invaded the blood-stream, treatment with proflavine is apparently of little or no value. These results are similar to those previously obtained with sulphanilamide (McIntosh and Selbie 1941), except that in delayed treatment the preventive action of proflavine is greater than that of sulphanilamide. When the effect of 0.5 mg. of proflavine ill also be an economic problem for other hospitals and it seems likely that, at a moderate estimate, several onths must elapse before the psychotic population can e catered for

The following scheme was carried out on the male ulation—about 1100 patients—in this hospital n May, 1941, onwards the erythrocyte sedimentation- of every patient in the hospital and of every new ission was measured, excluding those already ill with own active organic disease Those with sedimenta- s of over 14 mm per hour were radiographed les other active organic disease was found to account or creased rate Those with sedimentation-rates 7 and 14 mm per hour were tested a few weeks in if the rate had risen to 14 mm per hour, or over were also radiographed Altogether 384 X-ray graphs were taken, but in this number were luded some examined a second time for follow-up rposes

It has long been recognised that the sedimentation-rate s not per se a diagnostic method—that in fact it is erely an index of active organic disease More import- nt still, active tuberculosis has been known to exist in he presence of a normal sedimentation-rate, as Trail entions The real question is, how often this anomaly s found. We suggest that it is rare In 16 months xperience of this method, in the course of which many housands of sedimentation-rates have been performed, e have not yet found a case of active pulmonary tuber-ulosis having a sedimentation-rate within normal limits

Of those radiographed 90 showed appearances of ctive disease, and 26 were considered to be suspicious— total of 116 cases These cases have been observed ver a year The average loss of weight per person rom June, 1938, to June, 1941 (when the disease was diag-osed), for the 116 cases was 14½ lb, to the nearest ½ lb his may be compared with an average loss of weight in 82 ambulant non-tuberculosis patients of 8¼ lb over he same period During the investigation 54 of the 116 atients had pyrexia of varying degree, and in 17 ubercle bacilli were found in the sputum, fæces, or leural fluid The fact that the bacillus was found in uch a small number of cases was partly due to the early tage or low activity of the disease in many cases, but lso to lack of cooperation from patients in providing putum The deteriorated type of schizophrenic who eemed most prone to this disease, coughs but little and wallows his sputum Bacteriological investigations ust therefore be made on the fæces, by culture on Lowenstein-Jensen medium

With a few exceptions our patients were treated in bed or a time, the aim being to bring the sedimentation-rate ack to normal limits On the whole this method was airly successful (see table)

SEDIMENTATION-RATES BEFORE AND AFTER TREATMENT

Sedimentation rates mm. p h.	Number of cases		Sedimentation rates mm p h	Number of cases	
	At times of diagnosis	At end of review		At times of diagnosis	At end of review
100+	1	0	40–	10	6
90–	0	0	30–	21	6
80–	2	1	20–	31	22
70–	5	3	14–	30	17
60–	6	1	5–	3	46
50–	6	2	1–	0	11

Of the 116 cases, 40 still remain in bed, 70 are ambulant and 6 have died of pulmonary tuberculosis The average gain in weight during treatment has been 6¼ lb The results of examination of sedimentation-rates for 1942 (excluding the 7–13 mm p h reports which are not yet complete) have exceeded expectation The total number of high sedimentation-rates has been lower, and after excluding other causes only 52 patients were found to require radiological examination Of these 14 were considered by the radiologists to show signs of active disease, and 9 to be suspicious, a total of 23—almost half those radiographed

The method entails much less labour than might be thought, blood being taken and sedimentation tubes filled in the ward All patients in bed are weighed weekly, and sedimentation-rates of all cases are estimated monthly In this way activity in an ambulant case is readily detected—a point of great importance we think, since many of these cases are stuporous and inaccessible The sedimentation-rate of all patients is again being investigated at the beginning of the second year

Technique—A 2 c cm Record syringe with a small-bore needle is filled to the min 8 mark with 3 8% sodium citrate, and blood is drawn up to the min 40 mark The contents are mixed in the syringe, ejected into a centrifuge tube, drawn up 5 times in a Westergren 200 mm tube and placed in the rack Readings (taken at bottom of clear fluid level) are taken at the end of the first and second hours, and the SR calculated according to the formula

$$\frac{A+\frac{B}{2}}{2} \quad \text{where } A = \text{first hour reading and } B = \text{second hour reading}$$

The sodium citrate when issued in bulk was prone to develop moulds, and we are indebted to Mr R H Henriksen,[3] then pharmacist at this hospital, who found, after a number of experiments, that phenylmercuric nitrate did not affect the sedimentation-rate It preserves the citrate solution when added in 0 002% dilution

As the MRC report clearly shows this is not essentially a war-time problem of the mental hospitals, adverse conditions must already have been present during peace A disproportionate number of our patients were found in the "wet and dirty" ward of the hospital Here we find the deteriorated psychotic, doubly incontinent, mute and inaccessible patients, uncooperative in the extreme We suggest that it is this type of ward which is the nidus of tuberculosis (and dysentery) in mental hospitals, and that unless objective examinations are often carried out on these patients, they will disseminate their disease before they are discovered

In peace-time we may find our method not ideal, but at present we suggest it as an efficient stop-gap

We wish to thank Dr W Allen Daley, medical officer of health to the LCC, and Dr W A Caldwell, medical superintendent of this hospital, for permission to publish these results, and the LCC Central Pathological Laboratory, and the radiological staff of an EMS hospital for their help

SEVERE deficiency of vitamin A has long been known to result, in animals and man, in keratinisation of the conjunctiva and sometimes also of the cornea Severe deficiency of riboflavin in rats was shown by Bessey and Wolbach (1939) to lead to corneal vascularisation American workers have recently suggested that mild deficiency of either of these dietary factors results in slight conjunctival or corneal changes which can be detected by examination with the slit-lamp Kruse (1941) describes a continuous series of abnormalities of the conjunctiva which he believes express stages of severity of deficiency of vitamin A Beginning with the normal eye, in which both the superficial and the deep layers of the conjunctiva are smooth and transparent, he describes a gradual diminution in light transmission, the conjunctiva becomes wrinkled, the deep and then the superficial layer becomes translucent and later opaque, and eventually discrete raised keratinised patches —Bitot spots—are seen, mild lacrimation and photophobia are observed during the examination

With regard to deficiency of riboflavin, Sydenstricker and his co-workers find an increased limbal vascularisation (Sydenstricker et al 1940, Kruse et al 1940) According to their description, in the earliest stages there is an engorgement of the limbic plexus and an increase in the number of capillary loops, which extend to the corneoscleral junction Later, the cornea itself is invaded by capillary "streamers" running centripetally, in the

the last war, presumably through their inability to reach bacteria situated inside the tissues But we have shown that proflavine is not only more active than sulphanilamide in preventing the development of *Cl welchii* infection in mice but that it is at least as active as sulphanilamide and sulphathiazole in an infection that has already developed Proflavine has also the advantages of being bacteriostatic to a wide range of organisms and of having a low toxicity to tissue, as Garrod (1940) has emphasised Although Jacoby, Medawar and Willmer (1941) found that proflavine is toxic to fibroblasts in tissue culture, Russell and Falconer (1941) and Manifold (1941) have shown that neutral solutions of proflavine are less toxic than sulphonamides to brain tissue The recent experience of Mitchell and Buttle (1942) has also shown that large quantities of proflavine can be inserted in wounds with good results In the doses we have used we have seen no injurious effects in mice In clinical practice, however, large doses of proflavine should be neutralised immediately before application because much of the irritant effects of this drug are due to its high acidity Much of the criticism that has been directed against the use of the acridine drugs in wound infections has been based on previous experience with acriflavine which is much more toxic than proflavine and should not therefore discourage further trials of proflavine in wound therapy As Garrod (1940) has pointed out, proflavine is also much more easily prepared and of more regular composition than acriflavine, which is a mixture of compounds, so that proflavine is the drug of choice at the moment We have experiments in hand on the effects of the new acridines described by Albert and others (1938) and Rubbo, Albert and Maxwell (1942) in clostridial infections

The therapeutic action of penicillin on *Cl septique* infection in mice was investigated by Chain and others (1940) In an infection which killed all untreated mice within 24 hours they were able to save all mice receiving repeated injections of penicillin In our experiments the injection in the infected site of a single dose within 2 hours of infection was sufficient to save a high proportion of mice subjected to a severe infection Compared with proflavine and the sulphonamides it appears to be the most powerful of the therapeutic substances that we have yet tested experimentally against this type of infection It is also noteworthy that, judging by the statement of Florey and Jennings (1942) that 20 mg of therapeutic penicillin containing 40–50 units per mg caused serious embarrassment but not death in a mouse, the effective dose in our experiments is only about a 20th to a 30th of the toxic dose The great therapeutic power and the low toxicity of penicillin seem to warrant extensive clinical trial when enough of this substance becomes available

Gramicidin, another naturally occurring antibacterial substance, provides a striking contrast to penicillin In spite of its great activity in vitro against *Cl welchii* it has proved in our hands to be of little value against *Cl welchii* infection in mice It has also the great disadvantage of being highly toxic

The various substances that we have tested fall into two distinct groups In the first are the oxidising chemicals, zinc peroxide and hyperol, which appear to possess only an antiseptic action, because when their application to the infected site is delayed they fail to exercise preventive action In the second group are the sulphonamides, proflavine and penicillin, which can be given after an hour's delay and still prevent infection to a large extent The latter may be said to have selective chemotherapeutic action in that they can reach and exert their bacteriostatic effects on organisms that have invaded the tissues When the infection becomes generalised the curative action of the local application of these substances is much reduced and with the exception of proflavine and penicillin is ineffective

SUMMARY

The local application of zinc peroxide is apparently of no value in preventing the development of *Cl welchii* infection in mice when the organisms have invaded the tissues

Proflavine is of greater value than sulphanilamide and is at least as good as sulphathiazole in the local prophylaxis and treatment of *Cl welchii* infection in and its use therefore as a wound dressing should further explored

Penicillin, injected at the site of infection hours of infection, is a powerful prophylactic *Cl welchii* infection in mice and is superior to and the sulphonamides in this respect

CONTROL OF PULMONARY TUBERCULOSIS IN MENTAL HOSPITALS

W P BERRINGTON

WEST PARK HOSPITAL, EPSOM

THE report of the Medical Research Council's committee on tuberculosis in war-time[1] and Trail's comprehensive study[2] have dealt adequately with tuberculosis in the general population The committee have also investigated the present situation in mental hospitals, but as far as we are aware no figures based on research in these hospitals exist We present here the results of such research on a small community of male psychotics, and suggest a method for the control of tuberculosis in this type of community—a method owing its inception entirely to the economic exigencies of the moment

In May, 1941, it became obvious that the mortality-rate from pulmonary tubercle, particularly in the male population of this hospital, was rapidly increasing Looking up our records, we find that deaths from this disease from 1932 to 1941 were as follows

1932	*1933*	*1934*	*1935*	*1936*	*1937*	*1938*	*1939*	*1940*	*1941*
7	7	9	5	6	8	10	11	15	27

During these years the male population of the hospital remained stationary at about 1100

In the MRC report we find that mental hospitals have had, at least since 1910, the reputation of eclipsing the mortality-rate in the general population Thus in peace-time the rate was 9 or 10 times that of the general population and rose to more than twice its peace-time rate in 1918 Now, the rate has again risen steeply, to a greater extent in the males than in females Measures advocated for early diagnosis—chiefly mass miniature radiography—are now well known and have already, to some extent, been put into practice among the general public This method, to some extent and in due course, will doubtless be put into operation in mental hospitals The questions we must ask are to what extent, and in what period of time ?

It now seems certain that X-ray facilities will be made available to all mental hospitals, but not apparently in the form of mass miniature radiography To quote from the report—" the Committee therefore recommends that efforts should be made, so far as possible, to take periodical chest radiographs of all residents, whether they have symptoms or not, in order to discover and treat early cases Many hospitals already have X-ray apparatus suitable to this purpose " In other words some hospitals will still be committed to taking full sized X-ray photographs In our own case we viewed the expense of this programme in 1100 patients (or, including females, over 2000) with dismay, and we think that this

B and G = Boys and girls

In addition to these changes in the epithelium, we have noted 17 children in whom a thickening or cystic change is present in the deeper layers of the conjunctiva This was usually observed near the plica semilunaris and it was apparently not associated with either sex or age

SLIT-LAMP MICROSCOPY AS A MEANS OF DETECTING DIETARY DEFICIENCY

Corneal vascularity—By taking, as we have done, actual invasion of the cornea as the criterion of abnormality, we may have failed to include some cases of mild ariboflavinosis Some of the children with a high degree of vascularity confined to the limbus were probably instances of this sort But only a therapeutic test would prove this and this we have not done Invasion of the cornea itself by capillaries from the limbus is more likely to be of definite dietary origin, and by considering only children showing this we think we are dealing with cases of real deficiency

Conjunctival findings—The rôle of vitamin A in the production of the conjunctival changes is obscure It is agreed that severe deficiency of vitamin A leads to keratinisation of the conjunctival epithelium a condition variously referred to as xerophthalmia, keratinisation or xerosis conjunctivæ There is usually generalised or localised opacity of the conjunctiva due to metaplasia of the epithelium The localised lesions when severe, consist of dry raised chalky-white "foam-like" plaques; these constitute the "Bitot spots" The epithelial changes may extend to the cornea, and if severe enough may lead to the dryness and ulceration referred to as keratomalacia

Kruse maintains that, in examining a number of individuals with the slit-lamp, he can grade them in a continuous series ranging from those with perfectly normal, transparent conjunctivæ to those having characteristic Bitot spots As intermediate grades, he recognises first a translucency then an opacity in one or more zones, and he claims that the changes represent various stages in the development of xerophthalmia due to deficiency of vitamin A. In other words, according to Kruse, examination of the eye by the slit-lamp may be used for the detection of early signs of deficiency of this vitamin. In fact, Wiehl and Kruse (1941) in the survey already mentioned definitely class subjects with these conjunctival findings as showing avitaminosis A Several considerations however indicate that the relationship between these lesions and vitamin A is by no means so definite We have already pointed out that changes induced in deficiency of vitamin A are known to affect the conjunctival epithelium, but the changes reported by Kruse, unlike those we describe, are in the subepithelial layers of the conjunctiva While the present report was being prepared, a paper has appeared by Berliner (1942) which strongly criticises the conclusions of Kruse for this and other reasons Berliner's chief arguments are as follows

1 The majority of the "spots" described by Kruse are almost certainly pingueculæ, in which the changes in the conjunctiva are not in the epithelium, where deficiency of vitamin A shows itself, but in the subepithelial layer

2 Most of the subjects with positive slit lamp findings have normal levels of vitamin A in the blood

3 The changes are more common in the higher age-groups

Berliner considers that most of the changes are normal presenile or senile alterations and are not prexerosis, xerosis or Bitot spots due to deficiency of vitamin A None of our children had conjunctival opacities as described by Kruse but we have seen just such opacities in adults, our experience leads us to conclusions similar to those of Berliner On the other hand, certain of Berliner's arguments are not so devastating as at first appears The level of vitamin A in the blood at least in adults, is not a sufficient criterion of vitamin-A nutrition, poor dark-adaptation which can be cured by the vitamin often coexists with quite high levels of vitamin A in the blood (S Yudkin 1941) Moreover, the fact that the conjunctival findings are more frequent in older subjects does not necessarily mean that they are normal findings due solely to age, it is possible that they are due to prolonged mild deficiency of the vitamin, so that they would naturally be more often seen in the higher age-groups It is clear that the question of the relationship between the conjunctival changes of Kruse and vitamin-A *deficiency must still be regarded as open*

Probably the most serious objection to Kruse's view is the fact that the changes he describes are in the subepithelial layers of the conjunctiva For this reason we feel that any early signs of vitamin-A deficiency will more likely be shown in studies such as ours which are concerned with epithelial findings, although at this stage we certainly do not claim that any one of the findings we describe is in fact an index of deficiency of vitamin A Further work is clearly necessary We are now examining the effect of prolonged vitamin therapy on these children and this may help to demonstrate whether vitamin A plays a part in the production of the epithelial changes

The opacities in the subepithelial layers of the conjunctiva which the American workers have described were not seen by us in children, but the epithelial findings in children which are reported here can also be distinguished in adults Moreover the epithelial findings in adults are in no way correlated with the presence or absence of opacity in the deeper layers We therefore suggest that, if other workers would also record their observations in the epithelium as well as in the deeper layers of the conjunctiva, it would probably help to hasten the elucidation of the cause of these changes

DISTRIBUTION OF FINDINGS IN DIFFERENT SCHOOLS

Corneal vascularisation—As we have said, the degree of vascularity which we have taken as abnormal is almost certainly due to riboflavin deficiency There are two possible reasons why more of the older children show this deficiency The first is that all the children have been subjected to a similar mild deficiency and the older children have consequently had a longer time in which to develop the signs Alternatively, it may be that the distribution of milk in schools, which has increased greatly in recent years, has meant that the younger children have had a more liberal supply of milk and hence of riboflavin than the older ones

Conjunctival epithelium—The interpretation of the differences between the schools in respect to the number of children showing positive epithelial findings is less more advanced stages these may anastomose and form arcades from which further streamers arise. Symptoms of lacrimation and photophobia are more noticeable than with the keratinisation; other changes due to ariboflavinosis, such as cheilosis and glossitis, are frequently present.

The only survey so far reported in which these slit-lamp examinations have been made is one by Wiehl and Kruse (1941) in New York. They examined some 500 high-school pupils of a low income level, 300 high-school pupils of a high income level and 140 adults employed by the WPA. The students were between 12 and 20 years of age, the adults between 17 and 65. Conjunctival changes (referred to by them as "avitaminosis A") was found in nearly 90% of the poorer children and nearly 100% of the workers (the conjunctivæ of the better class children were not examined). Corneal vascularisation was found in 2% of the wealthier children, 75% of the poorer children and about 40% of the workers.

During a nutritional survey of 1100 Cambridge schoolchildren carried out in January and February, 1942, 496 of the older children were examined by slit-lamp microscopy. We record our results at the present early stage not because we have discovered the cause of the findings we describe, nor even because we are able to define what is normal and what abnormal, but because the use of the slit-lamp for nutritional surveys is very recent and a description of the common types of findings may help in the adoption of a uniform classification and nomenclature.

The children examined were from three elementary schools—two junior and one senior school. Junior school A was in a poor district of the town; junior school B and the senior school were situated close together in a fairly well-to-do part of the town. The children examined at the junior schools were between 8 and 10 years of age; those in the senior school were all 11 years old. About equal numbers of boys and girls were examined.

RESULTS

Corneal vascularity.—Our observations in regard to the increased vascularity at the limbus, ascribed to early ariboflavinosis, resembled the changes described by the American workers. We have, however, classed as positive findings only those degrees of vascularity in which there is actual invasion of the clear cornea. In children showing these changes the limbic plexus showed congestion and proliferation, and capillary streamers arising from it extended centripetally beyond the corneoscleral junction. This invasion when present was always seen round the entire margin of the corneoscleral junction and there was never any appreciable difference in degree of vascularity between the right and the left eye. By taking as abnormal only those eyes in which blood-vessels invade the clear cornea we have adopted a somewhat severer criterion of abnormality than Sydenstricker and his co-workers. These observers class, as an earlier stage of abnormality, a proliferation and engorgement of the limbic plexus; invasion of the cornea, in their view, is a later stage of the same pathological process. Thus, by our taking as abnormal only the latter findings, it is likely that we have included only cases of true ariboflavinosis. This is supported by the observation (J. H. K.) that changes similar in type and extent may be seen in adults, and riboflavin in these cases induces obliteration of the capillaries, while there was no sign of any other possible cause for vascularisation. Altogether, 19 children were found with corneal vascularity (see table). The proportion was significantly higher in the older children—1·5% of the children at the junior schools compared with 8% of those at the senior school. The difference in incidence between boys and girls was not significant.[1]

Conjunctival epithelium.—Kruse's description of the changes in the superficial and the deep layers of the conjunctiva refers to adults and adolescents and we have seen in adults also conditions closely resembling those Kruse described. In the children, on the other hand, the conjunctiva was altogether more transparent and it was impossible to follow the classification adopted by Kruse (see discussion). Moreover, we felt it of greater importance to concentrate on the epithelial changes rather than those of the subconjunctival tissue, since it is in the epithelium that vitamin-A deficiency is known to show itself. For these reasons, we have adopt different classification for our findings. Five have been differentiated, as follows:

Group 1.—Smooth, transparent conjunctival epithel

Group 2.—Transparent epithelium with wrinkling, usually located midway between the limbus an caruncle or external canthus, or nearer to the limbus wrinkles form networks of various shapes, but those n the limbus are often arranged concentrically to it. Ther no opacities or thickening of the subconjunctival tissue

Group 3.—The wrinkling is more pronounced. Here there, mostly on the top of the wrinkles, are seen fine p reflecting the light, which do not disappear when viewed different angles. No opacities in the conjunctiva are vis

Group 4.—The points of reflection seen in grade 3 appe have aggregated, forming small islands with a definite opacity. At the edges of these opaque islands are seen p of reflected light resembling those in group 3. The opac are of various shapes, most often round or oval. They are dead-white or milky colour and are not raised above surrounding tissue.

Group 5.—The opaque areas are larger than in group 4 without points of reflection at their edges.

Let us say at once that the differences between groups are very slight and it may be thought that we making an unnecessarily fine division. Yet experienced no difficulty in distinguishing the gr in most of the children, and at this early stage knowledge concerning these changes we think it better to err on the side of over-differentiation rather than class together slightly different findings which may eventually be shown to be due to quite different causes.

We have intentionally referred in our classification to groups rather than grades since we do not at present stress the claim that they represent a continuous series of increasing amount of change. It is however likely that in fact they represent such a series. First, although it is usually not difficult to determine into which group a child should be placed, it is possible to range the children, beginning with some in group 1 and ending with some in group 5, in such a way that the differences between successive children are very slight indeed. Secondly, the distribution of the children among the five groups suggests that the groups represent grades of change in a continuous series. Thirdly, in all but 30 of the 496 children examined, the two eyes showed findings characteristic of the same group. Of the 30 in which this did not obtain, the difference in 22 was only of one group and in the remaining 8 of two troups.

Our findings are summarised in the table. After statistical analysis[1] the facts which emerge are these. Considering the boys and girls together, there is no difference between the two junior schools, but children from each of the junior schools show fewer positive findings (i.e., groups 2–5) than those in the senior school. Boys show fewest positive findings in junior school B, more in junior school A, and most in the senior school; among the girls there is no such difference between the schools. In junior school A and in the senior school, a smaller proportion of the boys than of the girls are in group 1, but this sex difference does not show itself in junior school B.

We do not know the ultimate cause of the conditions we have described and it is possible that many factors are involved, but our results suggest that three of the factors which play a part in producing these conditions are age, sex and economic status. Between the ages of 8 and 11 years, it seems, age and economic status affect the conjunctivæ of boys but not of girls. By the age of 11, the conjunctival changes in children of a good economic status are seen more frequently in boys than in girls, although at the age of 8 this difference does not exist. In children of a lower economic status the difference between boys and girls shows itself at age 8

---

[1] The comparison between two sets of children—i.e., boys with girls or one school with another—has been made by comparing the proportions with positive findings in the two cases. A difference between two sets of children is taken as significant if the difference in these proportions is greater than twice its standard error—i.e., the difference would arise by chance once in twenty times or less often. For example, to test the significance of the difference in conjunctival findings in junior school A with those in the senior school we have compared the proportions 74/149 and 116/191. Analysis shows that the difference in these proportions is 2·1 its standard error and hence is significant.

TETANUS IN WAR-TIME

TETANUS, like gas gangrene, requires a particular set of circumstances for its occurrence It needs, firstly, a manured soil, for the causal organism and its resistant spores live in and are shed from the intestine of many animals Thus, *Clostridium tetani* was found in 27% of 193 samples of soil from the European battle zones in the 1914–18 war[1], it was present in 57 out of 79 samples from the cultivated fields of England, but not at all from the "wilds of Scotland"[2], and now, in our opening pages, BOYD and MACLENNAN admit recovering it from only 8 8% of 91 samples collected between Daba and Benghazi during the present campaign in the Middle East The second requirement is a wound which will encourage germination of the spore and toxin-production by the tetanus bacillus Such are usually deep penetrating wounds with much necrosis of tissue or the presence of foreign bodies, and the rarity of tetanus after civilian accidents in peace-time is probably related more to the nature of the injury than to the absence of the infecting organism Occasionally, however, tetanus develops after apparently trivial and surface wounds Sepsis, and particularly the toxins of other anaerobes, also facilitates the onset of tetanus The third requisite is the bringing together of the infective material (soil or soiled clothing or other foreign body) and the necrotic tissue plus a time-interval to allow germination and toxin-production These three conditions are frequently fulfilled in war-wounds, whether suffered on the battlefield or in the bombed town, and prophylactic measures against tetanus therefore become of prime importance in war-time

Tetanus has apparently been uncommon among air-raid casualties in this country There are two possible explanations (1) Most cases are quickly dealt with surgically, and surgical removal of necrotic tissue or foreign body still plays an essential part in the prophylaxis of tetanus as of gas gangrene, (2) tetanus antitoxin was given prophylactically to most of the air raid casualties Yet cases of tetanus have occurred in spite of a prophylactic dose of antitoxin, e g, RADLEY SMITH[3] reported 7 cases of tetanus with 3 deaths among civilian casualties during a two-year period in one London sector 6 of them had been given one prophylactic dose of tetanus antitoxin During the same period, SMITH saw no case of tetanus among a much larger series of Service casualties, many of them evacuated from Dunkirk Indeed, BENSTED[4] records only 8 cases of tetanus after the episode on the Western Front, all of them in soldiers not actively immunised As large-scale active immunisation has not been practised among the civil population, and as one dose of prophylactic antitoxin may not protect against tetanus, the instructions regarding the use of tetanus antitoxin for air-raid casualties have been amended (E M S Gen/33 and E M S I 351) so that every injured person, however trivial the wound, is to be given an initial dose of 3000 units of antitoxin when first seen at F A P or hospital, with two further weekly injections if the individual has not been actively immunised If the injury is severe, the doses should be increased two or threefold

Active immunisation with tetanus toxoid is now a routine procedure in the Services, and, though a voluntary measure, the rarity of reactions means that some 95% of recruits accept it Two doses of toxoid at an interval of 6 or more weeks produce an antitoxin response above the 0 01 unit per c cm which is regarded as the basal immunity level, but in a proportion of cases the titre falls below this level after some months[5] A third dose of toxoid is therefore given 6–12 months after the primary inoculation, and this third dose "boosts" the antitoxin content to remarkably high levels (2–50 units per c cm) although the response may not occur until after 5 days[6] Because of this lag-period and because a few individuals may fail to respond at all, it is a regulation in the British Forces that every man shall be given a prophylactic dose of tetanus antitoxin at the time of wounding These precautions are not always carried out, and even when they are, tetanus may rarely supervene as BOYD and MACLENNAN have shown in their Middle East series of 18 cases, 5 of them among immunised troops, giving an incidence of 0 13 per 1000 wounded, and 13 among non-immunised men, giving an estimated incidence of 1 6 per 1000 That the risk of contracting tetanus was not inconsiderable is suggested by the finding of 18 toxigenic strains of *Cl tetani* in 214 wounds of a severe type Incidentally, it was perhaps more than a happy chance that a bacteriological expert on the plectridia (the terminal-sporing anaerobes) was available to differentiate the wheat from the chaff, for plectridia are commonly found in war-wounds, and their isolation and identification is no mean task

Interest in this series of cases attaches principally to the occurrence of tetanus in men who had been actively immunised In one patient, who recovered, there was only hearsay evidence about the infection The other non-fatal case was a Maori who had been given two doses of toxoid a year previously and who developed a mild tetanus 13 days after a bullet-wound of the forearm Of the three fatal cases, the first, an Indian, developed signs of tetanus 6 weeks after a cut in his hand, and he died 5 days later with a ruptured pulmonic cusp The development of tetanus in this case can only be explained on the ground that the patient was non-immunisable The other two cases fall into a different category In both there was extensive necrosis of tissue, without much frank sepsis, so that the tetanus bacillus was left undisturbed to manufacture its potent toxin In the one, who had been immunised 20 months previously, symptoms developed in 5 days and the patient died 36 hours later In the other, who had been given a boosting dose of toxoid three months earlier, the onset was delayed until the 9th day, but the large amount of toxin apparently swamped what should have been a more than adequate immunity More radical surgery at the time of wounding would have probably saved both lives In neither case was prophylactic antitoxin given, which raises the question "Would prophylactic antitoxin have prevented the onset of tetanus?" Opinion is still divided about the advisability of giving easy, since, unlike the corneal vascularity, we have not been able to decide on their cause, nor even to define limits of normality All we can say is that, if in two schools there is a significantly different distribution of the children among the five groups of epithelial findings, the factors concerned in their production must be present to a different extent in these schools. We can then state definitely that, whatever the causes of the positive findings in the epithelium which we here describe, they exist to a greater extent in the poor class junior school than in the better class junior school Our results indicate that the epithelial findings are associated with age, economic status and sex, being commoner in the poorer class school compared with the better class school, in boys rather than girls, and in older rather than younger children But until further data are available it would be speculative to do more than record these differences

CORRELATION OF SLIT-LAMP FINDINGS WITH OTHER FACTORS

The examination of the eyes of these children by slit-lamp was part of a more exhaustive survey. Among other tests carried out were clinical examination, especially for signs of dietary deficiency, examination of the fundus oculi and measurement of visual acuity, examination of the teeth, measurements of height and weight, estimation of hæmoglobin, estimation of grip with a hand dynamometer, measurement of intelligence and of educational attainment A record is also being kept by the teachers of general behaviour and performance in schools and of absences and illnesses These results are now being analysed with a view to determining possible correlations between the various measurements We can already say that the slit-lamp findings, both conjunctival and limbal, are not correlated with height and weight (or Tuxford's height-weight index), hæmoglobin, dark-adaptation, intelligence or educational attainment

SUMMARY

An examination with the slit-lamp microscope has been made of the eyes of 496 elementary-school children in Cambridge, aged between 8 and 11 years

Corneal vascularisation, taken as an actual invasion of the clear cornea with vessels from the limbus, and said to be indicative of deficiency of riboflavin, has been found in about 4% of the children The proportion was significantly higher in older than in younger children

The importance of examining the epithelial layer of the conjunctiva is stressed Reasons are given for supposing that this is more likely to show changes due to dietary deficiency, especially deficiency of vitamin A, than examination of the subepithelial tissues according to the method of Kruse and his co-workers Opacities in these subepithelial tissues have not been observed in the children examined by us

Our observations have led us to classify the various findings in the epithelium into 5 groups The first contains those children whose conjunctival epithelium is perfectly smooth and transparent, while the other groups contain those showing varying degrees of wrinkling and opacity It is suggested tentatively that these represent 5 grades of increasing severity of change

The factors which appear to affect the production of these epithelial changes are age, economic status and sex Thus, children with smooth transparent conjunctival epithelium (group 1) are less common at the higher ages, in the poorer school, and amongst boys rather than girls It must be emphasised however that we do not know the cause of these epithelial changes, in particular, we do not claim at this stage that they are due to deficiency of vitamin A

We wish to record our gratitude to the teachers of the Cambridge schools, without whose cooperation this work would have been impossible

Reviews of Books

Annual Review of Physiology

(Vol IV) Editors J M Luck, V E Hall Stanfo University, California American Physiological Society and Annual Reviews Inc Pp 709 $5

An article in an annual review may range from a thinly disguised card-index to a mature and critical appreciation of new conceptions The former is too technical for anyone but the expert, and of little interest to him because he knows all about it already, nevertheless, it is a useful record, and changing authorship makes such surveys stimulating The present volume has used them to advantage, but also contains a high proportion of the more mature type of article General physiology is as usual well represented (permeability, effects of neutron rays, genetics, development, growth) and distinguished workers have contributed to the six articles bearing on neurology, electrophysiology and physiological psychology Subjects often neglected, such as water metabolism, the skin, applied physiology and drug addiction are clearly handled, and metabolism is well represented Reproduction, the kidney, the digestive system and the blood each receive a section, and there are two chapters on the circulation The wide perspective embraced by Peters and Shannon in their respective fields of water metabolism and the kidney, Ruch's tabloid explanatory method of dealing with the technical field of reflex action, and Long's careful arrangement of material on endocrines and metabolism are examples of skill in presentation especially worthy of note, though the same qualities appear in other articles Inevitably the authorship becomes more North American, but it is hoped that after the war the editors will enhance the value of their series by periodically introducing foreign points of view

Management of the Sick Infant and Child

(6th ed) Langley Porter, MD, William E Carter, MD London Henry Kimpton Pp 977 57*s* 6*d*

Since it first appeared ten years ago "Porter and Carter" has won justifiable popularity among English speaking pædiatricians This extensively revised sixth edition comes four years after the last In the preface many colleagues of the University of California Medical School and elsewhere are mentioned who have helped in the process of revision, especially the sections on allergy, blood and its disorders and in various parts of the book where the use of new sulphonamides is discussed Nearly a third of the new volume deals with therapeutic and diagnostic procedures, dietetic details and drugs This product of the California school is of a high standard

Illustrations of Surgical Treatment

(2nd ed) Eric L Farquharson, MD Edin, FRCSE, major RAMC, formerly clinical tutor and temporary assistant surgeon, Edinburgh Royal Infirmary Edinburgh E and S Livingstone Pp 391 25*s*

Mr Farquharson fills in some of the gaps left in most surgical textbooks, showing in detail how recommended procedures, apart from surgical operations, are most easily carried out Minor surgery demands attention to detail, and these careful descriptions with photographs should enable even the novice to apply the methods correctly The expert too will find much of value, for the book also contains many useful hints from a man who is obviously mechanically-minded The first section deals with intravenous infusion therapy, describing the most recent methods and substances employed The second gives useful tips on the application of mechanical and plaster-of-paris splints for various fractures and deformities, well illustrated by photographs He shows the Thomas wrench being used by the handle, some prefer to see it used as Thomas himself taught, with the operator's hands protecting the part, and his body-weight used as the correcting force The book ends with a series of plates showing surgical instruments; these have been well chosen and their uses are given in notes This section will prove valuable to candidates for surgical examinations who nowadays have little time to hang about the instrument rooms, process will be awaited with interest by all radiologists If the method is simple and gives constant results, this is an important contribution not only to cineradiography but also to mass radiography

MORPHIA AFTER INJURIES

UNTIL lately it was the practice to prescribe morphia for shock as if it was some specific remedy The larger the wound or the greater the shock the larger was the dose thought necessary And the doctor felt satisfied that whatever arguments there might be about the other methods of treating shock morphia in full doses had the blessing of the textbooks and experts Gradually during this war there has emerged the view that not only is morphia often unnecessary after injuries but there are definite dangers from its excessive use The *Army Medical Department Bulletin* for October says that morphia is given to many wounded patients who would do better with a cup of tea It also reminds the medical officer that the ideal is to give the smallest dose that will be effective, and that, though gr $\frac{1}{2}$ is reasonable for the severe injury with much pain and distress, after this dose no more should be given for at least four hours In the shocked patient poor absorption may lead to disappointing results from subcutaneous morphia and the intramuscular route is preferable If rapid relief is required, gr $\frac{1}{6}$–$\frac{1}{4}$, but never more, diluted to at least 1 c cm with sterile water, may be injected intravenously, taking a minute or more over the injection Intravenous morphia can often be given by injecting it through the rubber tubing (cleaned as if it were skin) of the plasma or blood drip that the patient is having; the ready made sterile solutions such as 'Omnopon' or 'Alopon,' which remain stable in solution, are convenient for this purpose When injection is impracticable one or two gr $\frac{1}{4}$ tablets work well if placed under the tongue The pharmacology of this practice is still doubtful With morphia, which is not acted on by gastric juice, it does not matter much whether absorption takes place through the buccal mucous membrane or lower down, but it would be worth while settling this question once and for all by some properly controlled experiments

In shock, the fall of blood volume reduces the transport available to carry oxygen to the tissues, and the aim must be to supply the needs of the vital centres by restricting the oxygen consumption of the less important tissues, such as the voluntary muscles Morphia does this by allaying the restlessness, due to pain, hæmorrhage or anxiety, and by damping down cell metabolism The use of morphia thus appears to be sound rational therapy But morphia also depresses the respiratory centre, so that breathing becomes both shallow and slow, and the consequent reduction in oxygen intake will add to the difficulties of the vital centres The shallow breathing also reduces the efficiency of the respiratory suction pump, so that the venous return is slowed There are other effects to be remembered With the low blood-pressure of shock the additional use of morphia may lead to cessation of urinary secretion The patient after large doses of morphia is almost poikilothermic, and has to be carefully guarded against changes of temperature Nevertheless, GRANT[1] has never seen bad results from gr $\frac{1}{4}$, and he says that when injured patients are in pain their low blood-pressure will rise to normal levels as the pain is eased by the drug He reminds us, however, that repeated injections may lead later to massive absorption as the circulation recovers and that chloral and bromides should not be forgotten NOSWORTHY[2] finds that by giving scopolamine with a much smaller dose of morphia the respiratory depressive effect of morphia can be avoided The neurosurgeon insists on the minimal amount of morphia for head injuries—certainly not more than gr $\frac{1}{4}$ The restlessness associated with head injury is better controlled by raising and padding the sides of the bed, and ROWBOTHAM[3] recommends phenobarbital gr 3 intravenously followed by chloral hydrate and bromides by mouth or rectum The chest surgeon finds that large doses of morphia postoperatively, after a chest injury, lead to lung collapse, within limits, the more these patients are made to move and not "mollycoddled," as PRICE THOMAS puts it, the better Thus the practice of using morphia as a routine postoperatively, for every injury, and for shock or suspected shock, needs checking Pain, and restlessness due to anxiety or hæmorrhage are the true indications

AUSCULTATION UP TO DATE

IN what he calls by the rather cumbersome name of a phono electrocardioscope, G E Donovan has introduced an instrument which holds out high promise of useful service to the clinician and medical student, as well as to the research worker As he described it in a lecture to the Institution of Electrical Engineers, the instrument incorporates a double-beam cathode-ray oscilloscope with a fluorescent screen of long afterglow, which permits of the simultaneous direct visual recording of two phenomena such as the phonocardiogram and electrocardiogram, the phonocardiogram and sphygmogram, or the electrocardiogram and sphygmogram At the same time the heart sounds, picked up by a special microphone, can be heard through an electrical amplifying stethoscope or a loud-speaker The instrument seems reasonably simple to work, and it is claimed that it is robust, cannot be damaged by overloading or shock, and that maintenance is simple A further advantage is that permanent photographic records can be obtained of the phonocardiogram, electrocardiogram or sphygmogram By means of frequency filters, murmurs or desired sounds can be accentuated and undesirable ones muted The instrument has an overall frequency range extending from the lowest frequency to over 1000 cycles per second, but this band can be divided by means of filters so that the frequency response of the apparatus can be given any desired slope, as is done by the "tone control" of a wireless set The most obvious application of the phono-electrocardioscope is in the teaching of auscultation Donovan says that the amplifying of heart sounds through a loud-speaker can never be 100% satisfactory, he much prefers multiple headphones, which can, of course, be used with his instrument It seems to be possible with this instrument for a group of students to hear (and see) the sounds actually produced by the heart, including those not audible to the human ear with the ordinary stethoscope, as well as the sounds and murmurs, reasonably amplified, which he should be able to hear with the simple stethoscope At the same time they will have visible evidence of the correlation of these sounds with the various phases of the cardiac cycle as demonstrated by the electrocardiogram Of the usefulness of the instrument in the clinic and the research laboratory there can also be little doubt antitoxin to an actively immunised and wounded soldier The American and Canadian Forces follow Ramon and give an additional dose of toxoid at the time of wounding, and as all American troops are given a boosting dose before entering a theatre of war, the antibody content should ordinarily be sufficient to deal with a tetanus infection without passive protection There still remains the rare non-immunisable individual, but it is obvious from the experience so far gained in this war that active immunisation, complemented always by early and efficient surgery, is a pretty sure safeguard against tetanus

MOVING X-RAY PICTURES

Cineradiography has been the dream of radiologists since 1896, when both rontgen rays and the cinematograph were in their infancy, but despite many ingenious inventions the method has not yet reached the stage where it can be applied to routine clinical work There are two possible ways of making a radiographic moving picture The first and most difficult is the so-called direct method where a long strip of X-ray film or a series of single films is moved in front of a selected part of the body and exposed in the ordinary way at predetermined intervals This method is costly and needs complicated apparatus, and the interval between exposures is too long In the second or indirect method successive photographs are taken of the image on the fluorescent screen Since the light value of a fluorescing screen is very low the problems of this method of cineradiography resolved themselves into securing a wide-aperture lens of suitable focal length, increasing the luminosity of the screen, and increasing the sensitivity of the film The optical problem has been solved by the development of the Zeiss R-Biotar *f* 1 0 85 lens Unfortunately increasing the luminosity of the screen or the sensitivity of the film results in loss of detail, because the former necessitates the use of a broad focus tube and the latter the use of coarse grain film Workers in different countries have approached these difficulties along different lines In England Russell Reynolds[1] increased the luminosity of the screen by increasing the output of the X-ray tube This entailed overloading a broad focus tube and exceeding the tolerance dose of X rays to the patient But Reynolds introduced a circuit breaker which automatically cut off the X rays as the shutter in the cine-camera closed He thus eliminated danger to the patient and was able to use a less broad focus tube with fine grain film Even then his maximum speed for cardiac work was only 25 frames per second, he was limited to a field of fixed size and the patient had to be in the erect position Stewart, Hoffman and Chiselin[2] in America, Torelli[3] in Italy and Kawaishi[4] in Japan used the same lens as Reynolds but employed a fine focus rotating anode tube with exposures well within the tube limits and the skin tolerance dose, and compensated for the low light value by using ultra-sensitive coarse grain film The larger the grain of the film emulsion the less the detail, so what was gained by the fine focus tube was lost by the coarse grain film Like Reynolds these workers had to use a field of fixed size in one position

Lately de Castro and Jany[5] of Brazil claim to have devised a camera attachment which overcomes the outstanding difficulties and a method of hypersensitising fine grain film which enormously increases its speed without corresponding loss of detail The apparatus consists of an expanding leather bellows, light tight and damp proof The large end of the bellows is hermetically closed by a fluorescent screen At the small end is a lead-lined case holding the cine-camera The bellows is supported on a tubular telescopic structure which allows the bellows to be expanded from 50 cm to 2 meters in length The telescopic support has a metric scale on which the distance between the camera and the screen can be quickly measured By turning the helicoidal thread on the lens to the corresponding distance on the external tube, the camera is automatically focused The sides of the lead-lined camera box are hinged so that there is free access for winding the camera and regulating the speed An electromagnet attached to the rear wall of the camera box allows the operator to start or stop the film from a distant control table This apparatus is attached to a standard motor-driven tilting table The exact method of attachment is not described but it is said that it can be put together or dismantled in a few minutes The device maintains the tube, the patient, the centre of the screen and the optical axis of the camera in perfect alignment The camera can be moved nearer to or further from the patient during the exposure and the tube can also be moved backwards and forwards during the exposure Lateral and rotary movements of the tube are also possible and remote control of the motor which drives the couch permits of the patient being moved from the erect to the Trendelenburg position during the exposure All the operations are carried out in daylight and the whole apparatus can easily be adapted for seriography, tomography and mass radiography

The Brazilian workers—radiologist and engineer—came to the conclusion that the only way to obtain adequate speed and detail was by increasing the sensitivity of fine grain film Hypersensitisation of film was attempted by Daguerre and film manufacturers have been experimenting with it ever since The principle consists in exposing the film to substances such as ammonia or mercury vapour shortly before it is used Up to the present no way has been found of accurately controlling this process Jany now claims to have done so but does not describe his technique He combines the action of mercury vapour with "several amalgams," and says that the hypersensitising should be done "in a glass jar, hermetically sealed and maintained at a constant temperature during a certain period, depending on the composition of the ingredients which constitute the photographic emulsion" With hypersensitised fine grain film and the apparatus described, the Brazilians claim to make cineradiograms safely and easily with detail nearly as good as full size film By hypersensitising coarse grain fast film they claim to take slow motion pictures of the heart at 64 frames a second Details of the hypersensitising capable of acute observation, and perhaps on such a foundation it will not be difficult to build a faith in the modern prophylactic immunisation for the growing number of diseases for which it is advised Plague, for instance, is no small problem in the Union, and Grasset has already placed the preparation of live avirulent plague vaccine on a routine basis He uses both the Tjiwidej strain from Java and the EV strain from Madagascar, these two avirulent strains of *Pasteurella pestis*, used in the living state, have acquired great reputations He has also developed combined immunisation against the typhoid group and tetanus Several cases of tetanus have arisen in men working in one particular mine shaft, soil from this mine was found to contain spores of *Clostridium tetani*, though samples of water were negative, investigations are in progress

Cancer has occupied the attention of Dr M J A Des Ligneris, to help in the discovery of predisposing factors he suggests that every member of the community should be provided with a detailed clinical history-sheet, forming a complete record from birth till death, this would help to elucidate not only the problem of cancer but that of many other conditions too, as practitioners in Britain will agree

FATIGUE FRACTURE OF THE TIBIA

A CONDITION in the tibia analogous to march fracture of the metatarsal bones has been found in X-ray examinations of children and adolescents complaining of pain around the upper end of the tibia or in the calf, and Hartley[1] has drawn attention to it as a potential cause of disability in young recruits Not only may a fatigue fracture of the tibia seriously interfere with training, and especially with marching, but when it is undetected slight violence may produce a complete fracture and long disablement In one such case observed by Hartley the subsequent fracture has led to the soldier's discharge Altogether he records 14 cases of fatigue fracture, in all of which the lesion was at the upper end of the shaft of the tibia, the site varying with the age of the patient from 1½ to 3¾ in below the epiphysial line The clinical history is usually of pain on standing, on walking, or after walking, with no history of injury The pain disappears when the limb is at rest Bilateral cases have been noted, but the pain has not been present simultaneously in both legs In 5 patients slight swelling was detected on the inner aspect of the upper end of the tibial shaft There was no local reddening or pyrexia, and tenderness was present only in 3 instances The patients came for radiographic examination 10–21 days after the onset of symptoms If the limb is rested completely spontaneous cure is certain, it occurred in every one of Hartley's cases The diagnosis rests entirely on the X-ray findings A small area of callus is seen in the lateral view behind the cortex at the upper end of the tibial shaft, in the anteroposterior radiogram callus is usually visible on the medial aspect of the tibia, but sometimes on the lateral aspect A tiny nick is also seen in the cortex of the bone, medially, laterally or both Later pictures will show an area of osteoporosis extending forwards from the posterior area of callus, sometimes with a fine irregular line of dense bone, the width of a hair, in its centre Rest increases the callus and causes sclerosis of rarefied bone In the healed fracture the posterior callus may have become organised into a bony buttress The radiological appearances may be definite within a fortnight of the onset of pain, but if uncertainty exists the examination should be repeated after another 7–14 days, absence of the typical appearances then is definite evidence against the diagnosis If a true fracture takes place at this particular site in the tibia, especially from slight violence, the radiogram should be carefully examined for callus If this can be demonstrated in a fresh fracture it must have occurred through an are weakened by fatigue fracture In Hartley's opinion th fatigue fracture is essentially a fatigue dystroph unassociated with inflammation or with direct violenc He regards the upper end of the tibia as subject t considerable strain, a fact which he thinks is demonstrate by the architectural structure and buttressing seen i normal radiograms Faulty crystalline structure, abno mal strain, or a combination of both at this vulnerabl site causes the bone to give way Hartley urges th importance of diagnosing fatigue fracture early in youn patients, so that treatment by immobilisation can b begun before time has been wasted and the patien exposed to the danger of a severe fracture

RABBIT DISEASES

THE Ministry of Agriculture, in two succinct bulletins, has summarised what the vast new body of rabbi keepers should know about the feeding and diseases o rabbits, and Gordon[2] has given more details about the diseases In the control of disease much depends o good husbandry, newly purchased stock must alway be isolated, hutches kept clean and manure never placed o ground that will be used to grow rabbit food The individua is usually sacrificed to prevent the spread of disease t other animals, unless there is some effective specifi treatment affected animals should be destroyed an burned, and thorough disinfection of the hutches carrie out Tuberculosis, most commonly from the bovin strain and acquired through infected cow's milk, affect rabbits, but does not as a rule assume epidemic propor tions Pseudo-tuberculosis, caused by *Pasteurella pseudo tuberculosis rodentium*, is an infectious disease closel resembling tuberculosis both clinically and pathologically and is usually fatal after a 3–4 weeks course of progres sive emaciation and weakness Snuffles, or contagiou catarrh, can be one of the most serious diseases in rabbitries, it can be acute but is more often chronic, and would pass for a persistent cold except for th accompanying wasting The cause is not established *Fusiformis necrophorus* infection (Schmorl's disease produces necrosis and ulceration of the skin, particularl of the face and head, and thickly walled abscesses i different parts of the body Affected animals move the jaws with difficulty and may develop pleurisy and pneumonia A condition in which a large abscess due to streptococcal infection develops in the region of the lower jaw is termed strangles The abscess should be opened and careful hygienic precautions observed Hæmorrhagic septicæmia is caused by *Pasteurella cuniculicida*, animals die within 24–36 hours and exhibit the usual symptoms and post-mortem lesions of an acute septicæmia Vent disease (rabbit syphilis), a venereal disease caused by *Treponema cuniculi*, is common in the rabbit but is less serious than human syphilis, affected animals have small scaly sores on the genital organs and when these are observed mating should be prevented The disease responds to the local application of mercurial ointments or the injection of neosalvarsan, it is not transmissible to man. Coccidiosis affects rabbits in two forms—the hepatic, caused by *Eimeria stiedæ*, and the intestinal, caused by *E perforans* Many adult rabbits are carriers In the most acute case—of the type which kills 70–100% of a litter—death occurs suddenly with no previous ill health and often no post-mortem lesions, although oöcysts can be demonstrated in liver preparations In less acute cases diarrhœa is usually followed by coma or convulsions immediately before death Adults develop progressive emaciation, pot-belly, and weakness of the hind legs. Multiple white nodules are found in the liver or intestine,

DEATHS IN THE THEATRE

Few statistical inquiries are less satisfactory than those which seek to establish the relative safety of different anæsthetics If it were possible for identical anæsthetists to give different anæsthetics in measured dosage to identical subjects undergoing identical operations by identical surgeons comparisons might be just, but it is not Three Johns Hopkins workers,[1] in an analysis of deaths in the theatre, lay little stress on this kind of comparison, though they do give percentage mortalities for the various anæsthetics used, actually these were not significantly different Lyford and his colleagues were anxious to determine the incidence of anæsthetic deaths and to see whether some of them might have been avoided They reviewed the records of 51,392 patients who had been given general or spinal anæsthetics for any surgical procedure except ophthalmic and obstetric operations during the ten years 1931–41 In this series there were 75 deaths in the theatre, an incidence of 1 5 per 1000 anæsthetics, of these, 55 were not, and 20 seemed to be, related to the anæsthetic Of the deaths thought to be unrelated to anæsthesia, 29 took place during difficult craniotomies, all the patients were in danger from increased intracranial pressure at the time of operation, and some died from hæmorrhage A further 16 patients died during chest operations, many of them being critically ill at the time Of the remaining 10 patients in this group, 6 seem to have died because of their poor condition at the time of operation, and 2 from operative hæmorrhage and shock during extensive surgical measures, one death was associated with absorption of an excess of adrenaline used in an attempt to control bleeding in a frontal sinus operation, the case-history of the last patient in this group was not available for study Of the 20 deaths which seemed to be related to the anæsthetic, obstruction of the main respiratory passages was held responsible in 4 cases In 3 this was by regurgitated stomach contents In the fourth, a hæmophiliac, an intranasal catheter was passed with the patient under ‘ Pentothal Sodium ’, it was thought to have reached the trachea, though it may have stopped short in the pharynx, 15 minutes later the patient showed signs of asphyxia and shortly afterwards died of œdema of the larynx Another 3 deaths were associated with spinal anæsthesia In 3 more the technique of administration of an inhaled anæsthetic seems to have been at fault, one was a patient with hypertension and a history of angina pectoris who was given nitrous oxide and oxygen followed by a small amount of ether for appendicectomy He died about 15 minutes after the start of anæsthesia and may have been short of oxygen throughout In the second case there was an inaccuracy in the flow-meter of the closed nitrous-oxide circuit which resulted in him getting 20% less oxygen than was supposed In the third case the patient responded badly to the anæsthetic (nitrous oxide and oxygen followed by ether), he might have survived if operation had been delayed until a satisfactory anæsthetic state had been achieved Another patient was receiving nitrous oxide, oxygen and ether for incision of a carbuncle, a cautery was used to check bleeding when in some way the anæsthetist received an electric shock through the patient and dropped the mask The anæsthetic mixture thereupon exploded and killed the patient In the remaining 9 cases no adequate explanation of the deaths could be found, though the poor condition of the patients was thought to be contributory in 4 The conclusion is that 11 deaths in the series could have been avoided—the 4 due to obstruction of the air-passages, the 1 due to explosion, the 3 due to faulty technique and the 3 due to spinal anæsthetics The gross anæsthetic mortality in the series was 0 039%, which is in line with rates reported by other observers

RESEARCH IN SOUTH AFRICA

The South African Institute for Medical Research has a reputation for work of distinction, in the report for 1941 the brief account given by Prof E H Cluver indicates that the standard does not fall The institute has turned its attention to war problems, Dr J H S Gear, whose work on typhus is well known, has been appointed to supervise the preparation of yellow fever vaccine after tuition in New York by members of the International Division of the Rockefeller Foundation Yellow fever exercises the African health authorities especially since its recent extension to the Sudan and Uganda, that the Union is within the sphere of possible spread is shown by the finding of the common vector, *Aedes ægypti*, at many points in the Transvaal, Natal and Cape Province But the existing records of this mosquito have been made principally in malarious country where mosquito collecting has been carried on, its actual range is certainly greater than present information indicates Malaria, of course, exists in the Union, Dr B De Meillon, who has wide entomological experience in the Union and Mozambique, has studied the properties of mosquito-repelling mixtures for use by the South African Forces Citronella is effective, but coumarin also shows great possibilities In an extensive trial, Dr E Grasset and Dr A R Davison, like workers elsewhere, have failed to confirm the good results reported by Collier in Thailand on the treatment of leprosy with diphtheria toxoid Pneumonia is a subject which the institute has long studied intensively because of the heavy incidence and high death rate in the past among native mine workers of the Rand Dr D Ordman has continued the bacteriological investigations initiated some 20 years ago, and it is on the basis of these, which display the shifting ætiology of the condition, that the wide system of prophylactic immunisation is based Sulphonamide therapy is of course largely used, but cases resistant to sulphapyridine are still cropping up, most of them are associated with *Staphylococcus aureus*, either as the sole infecting agent, or together with pneumococci or other organisms During 1941 the commonest pneumococci found in pneumonia were of types 1 and 2 Routine examination of lungs for silicosis and tuberculosis is made for the Miners' Phthisis Medical Bureau, the numbers submitted were slightly higher than in the 2 preceding years Ordman has undertaken the preparation, on a large scale, of vaccines against typhus of the classical louse borne type, murine typhus, and tick bite fever (a tick-borne member of the typhus group) Immunisation may prove a more effective means of controlling these diseases than any other, in the meantime the value of the vaccines has not fully been investigated in man, though that against the tick borne form may give satisfactory results if it is as potent as the Rocky Mountain fever vaccine

Ordman's activities included the investigation of an outbreak of relapsing fever, a disease first reported from the Union in 1912 by Park Ross, there were no further records until 1932, since when cases have been found in the northern Transvaal In the 1939 report de Meillon recorded it in the high veldt of the Transvaal, where it was associated with the presence of *Ornithodorus moubata*, the common vector of tropical Africa Ordman[1] finds that the spread of *O moubata* may in part be attributed to the fact that men of the Angoni tribe of Nyasaland, when travelling away from their own country, take with them a supply of these ticks, believing that immunity from relapsing fever can only be maintained if they are bitten by the ticks from time to time The African is

SINUSITIS AND THE COMMON COLD

R. M. DOWDESWELL M.D. CAMB
MEDICAL OFFICER, KENYA COLONY MEDICAL SERVICE

THE differential diagnosis of the conditions included under the term "common cold" is still vague and the treatment adopted is therefore apt to be uncertain in its direction. There is a particular tendency to overlook the part played by sinus infection in producing the symptoms.

Wynn (1942) divides common colds into two groups. The first, primary colds, are due to a virus infection and were found by Dochez, Mills and Kneeland (1936, 1938) to be unaccompanied by rise of temperature. The second group, secondary colds, are due to infection with the usual catarrhal bacteria which have become established in the tonsils, sinuses, nasopharynx, &c. after primary colds. The secondary colds are those mostly seen in practice because the primary ones are soon over. Jackson and Coates (1930) say that the attempt to differentiate between a sinusitis and an acute coryza or rhinitis "is more or less of a sophistry, the severe cold being called a sinusitis and the mild one a coryza." St Clair Thomson and Negus (1937) say that acute sinusitis "forms a part of many acute catarrhs which invade the sinuses by direct extension from a nasal catarrh."

The typical symptoms of sinusitis of course vary according to which sinus or sinuses are affected; many attacks produce no more than a "cold." In the chronic condition there is little tendency to spontaneous recovery. Among the symptoms of chronic sinusitis given in the textbooks are catarrh, nasal obstruction, chronic cold in the head, a discharge sometimes so slight that patients have unconsciously swallowed it for years, headaches, acute and chronic laryngitis, asthma, bronchiectasis, lack of power to concentrate, lassitude and even mental abnormalities. Ross Faulkner (in Jackson and Coates's textbook) writes: "Many a person has gone through life as a chronic invalid labelled a neurasthenic or hypochondriac, from an unrecognised pus focus in the nasal sinuses."

SIXTY CASES OF COMMON COLD

Study of 60 cases of common cold seen in private practice yielded some suggestive results. In this series, 39 patients had only occasional heavy colds or attacks called influenza; in 7 of these a definite diagnosis of sinusitis had been made at some time by the accepted methods. The remaining 21 patients had frequent or chronic heavy colds, and of this group a diagnosis of sinusitis had been made in 6. Only 3 of the diagnosed cases of sinusitis had had operations performed for this condition.

The patients in the "occasional" group all showed one or more of the following symptoms: chronic postnasal catarrh; frontal, occipital or one-sided headache; sneezing attacks; nasal discharge worse on one side and more copious either on standing up or lying down; tenderness over a maxillary or frontal sinus; pain in a sinus when the patient attempts to breathe in with the nose or mouth closed; slight swelling over a sinus; mild fever; lassitude and aching of limbs; minor facial neuralgia.

Cultures from the nasal discharge of patients with recurrent colds have shown more or less normal flora (usually *Staphylococcus albus* and diphtheroids) when taken between attacks but have yielded a heavy, pure or almost pure culture of a bacterium when taken during an attack. Organisms found in order of frequency have been: *Pneumococcus*, *Staph. aureus*, *Streptococcus viridans* of different types, and Pfeiffer's bacillus. The same organism was recovered in pure culture during separate attacks of a severe cold at intervals of many months from the same patient; in one case a *Pneumococcus*, type II, and in another Pfeiffer's bacillus. Two patients, both doctors, when examined by an ear, nose and throat specialist and radiographed during a clinical attack, proved to have had a long-standing chronic sinus infection which had never been suspected; they claimed to have been free from colds for years. In several cases giving a history and symptoms strongly suggestive of recurring sinusitis, X-ray examination showed no evidence of sinus infection.

In a case diagnosed as frontal sinusitis a mixed culture was obtained before and after one acute attack. A pure growth of *Staph. aureus* was recovered during the attack. Towards the end of this attack a slight diarrhœa was noticed; culture of stool yielded *Bacterium coli* and *Staph. aureus* in roughly equal numbers. As it happened a stool culture had been taken shortly before the acute sinusitis and had shown no staphylococci, and they were also absent from specimens taken after the attack.

Two patients, a husband and wife, had the wife's sister staying with them. The sister (who is not included in this series of cases and who had previously suffered from a "frontal sinusitis") developed a cold: a pure culture of *Pneumococci* was obtained from the nasal discharge. Within two weeks the husband and wife also developed colds; cultures from one yielded pure Pfeiffer's bacillus and from the other pure *Pneumococci*. The husband had on two previous occasions, 7 and 16 months before, yielded pure cultures of Pfeiffer's bacillus from his nasal discharge during a cold.

DISCUSSION

Some say that it does not really matter if a disease that resembles influenza is called influenza, acute sinusitis or something else. It might almost as well be said that it does not matter whether typhoid fever is called typhus or smallpox called chickenpox. If sinusitis passes as influenza the chances of curing an early attack, checking the spread of infection and of avoiding chronicity and possibly serious complications are much reduced.

Crooks and Signy (1936), Carmack (1931) and Mollison and Kendall (1922) as a result of routine antrum puncture in children have reported infection in these cavities in 22–30%. Ebbs (1938), as the result of post-mortem examinations on children, reported sinus disease in 30·6%. During childhood the frontal and ethmoid sinuses are only being developed and are less liable to obstruction than the adult sinus. Sinusitis is therefore probably much commoner in children and adults than is generally recognised. The diagnosis of acute and severe sinusitis is not difficult. After recovery from the acute attack X rays may show a clear sinus; this is not proof that no latent infection remains. A negative X-ray picture is evidence only of the absence of an empyema or of gross mucosal changes. The diagnosis of sphenoidal sinus infection is not so easy and its importance in relation to mental disease has been emphasised by Pickworth (1934) who brought evidence to show that infection may remain latent for years in the mucosa and even in the bone.

SUMMARY

Infections of the accessory nasal sinuses are prevalent in childhood as well as in adult life, and are often diagnosed as recurrent colds.

Case-histories and bacteriological findings suggest that apart from unmistakable cases of sinusitis, many are only mild and others have exacerbations of a chronic latent infection with possibly long quiescent periods; and that primary mild sinusitis may remain as a latent infection.

The possibility of sinusitis should be seriously considered and the sinuses investigated in any case of pyrexia of unknown origin, influenza or febrile catarrh.

CORRIGENDUM.—On page 418 of the article by Mitchell and Buttle (Oct. 10), for "Anderson (1940) found that 1/10,000 solution . . ." read "Stephenson (1940) found that 1/1000 solution . . ." The corresponding reference should read: "Stephenson, D. (1940) Personal communication."

and the bile-ducts may be seen as irregular white streaks on the surface of the liver The oöcysts which are passed with the fæces in both forms of the disease, and can be demonstrated microscopically, are not infective until at least two days after being passed In prevention, therefore, animals kept in runs should be moved on to clean grass every two days Food and water must be kept clean, and wire-floored hutches are useful All members of an affected litter should be killed, the bedding and droppings burnt, and the hutch scrubbed with 4% washing soda and then disinfected with a 10% solution of household ammonia Recently a disease, clinically rather similar to acute coccidiosis, has been prevalent in young rabbits Usually the rabbit is simply found dead, but there may be a few hours paralysis or convulsions before death It may be caused by a virus, but its ætiology is still being investigated at the Ministry of Agriculture Veterinary Laboratory, Weybridge Control measures as for coccidiosis should be carried out Rabbits are liable to favus and ringworm, the appearances and treatment being as in man Skin mange, produced by two kinds of mite, is particularly infectious and only valuable animals should be treated Ear mange or canker, also due to two mites, and leading to a violent otitis externa, may be treated with hydrogen peroxide to remove scabs, followed by a mixture of olive oil 20 parts and cresol or carbolic acid 1 part Benzyl benzoate preparations would probably be more effective Internal parasites of the rabbit are not important but the bladder-worm stage of the dog tapeworm *Cœnurus serialis* may cause subcutaneous swelling The cyst can be surgically removed and then destroyed

DIURESIS AND LACTATION

It has been the fashion to regard the initiation of lactation in terms of an antagonism between œstrogen and prolactin, or perhaps it would be preferable to say of a balanced endocrine relationship between the ovary and anterior pituitary This view, which carries the implication that sufficiently high doses of œstrogen exert an inhibitory effect on lactation, has been questioned by Meites and Turner[1] principally on the basis of their finding that the prolactin content of the anterior pituitary is not decreased but increased as a result of œstrogen administration This increase they look upon as indicative of an increased production of prolactin, which is taken to be a decisive factor in the initiation of lactation This contention, however, rests on the premise that prolactin is the specific lactogen hormone, a view which was severely criticised by Folley and Young[2] and which Turner[3] himself has lately seemed compelled to abandon Assuming that what may be called the œstrogen anterior pituitary antagonism theory is true, deficiency in lactation can be conceived, in many cases, as being due to a disturbance in the ovary-pituitary balance in the direction of a predominance of œstrogen Hypogalactia could then be treated in one of two ways—by administering anterior pituitary extracts or by measures which decrease the concentration of circulating œstrogen Hitherto the former method has been used almost exclusively, with varying and often disappointing results This is hardly surprising when it is remembered that purified preparations of prolactin (the pigeon crop gland stimulating factor) have been used in these trials and that Folley and Young[2] have pointed out that prolactin is only one of a complex of anterior lobe factors concerned in the initiation and maintenance of lactation Moreover, pituitary therapy, always expensive, has owing to war conditions become virtually impossible in many European countries Hence Geisendorf and Neyroud[4] of Geneva have been led to treat cases of deficient lactation by trying to hasten the post partum fall in the level of circulating œstrogen by the administration of the diuretic theophylline, the resulting increase in urine flow, they say, causing a rapid elimination of œstrogen from the body At first one ampoule containing 0 48 g of theophylline ethylenediamine was injected intramuscularly within two hours of parturition, but as these injections were painful the later cases received two 0 36 g suppositories during the twelve hours after parturition Their results in a large series, while possibly not fulfilling the exacting requirements of the modern statistician, are suggestive of success Clinicians who view with alarm the present decline in breast-feeding, and whose hopes of endocrinology providing them with a panacea for lactational deficiencies have hitherto been disappointed, might give the method a trial If the Swiss results are confirmed the position of the œstrogen inhibition theory will be strengthened

ARTERIAL LIGATURE FOR DUODENAL ULCER

The general poverty of the few foodstuffs available in Southern India are such that no treatment involving special diet over a long period is feasible Food there means rice and curry or tapioca and curry Working in this area, Somervell[5] therefore operates on the vast majority of duodenal ulcers, and in the last 20 years has done 2000 such operations He looks on the fractional test-meal in these cases as the most valuable guide to operative procedure and divides the acid curves in duodenal ulcer into four types—(1) high acid, (2) moderately high fasting acid rising to a high level in two hours, (3) very high fasting acid rising but *slowly after* the meal, and (4) high normal acid For the fourth type he advises gastroenterostomy alone, but in the others he now combines it with ligation of gastric arteries—" a kind of physiological gastrectomy, designed to reduce acidity promptly " Under procaine infiltration of the abdominal wall, reinforced if necessary by splanchnic anæsthesia, he begins on the greater curvature about two inches from the pylorus and proceeds to tie four out of every five arteries that he comes across until a point high up on the curve is reached The same process is then carried out on the lesser curvature Finally, through a window in the mesocolon he delivers as much of the stomach as possible and ties off four fifths of the greater curvature arteries on the posterior aspect which have not been tied already, and all the lesser curvature arteries which, without distressing the patient, can be persuaded to appear at the hole in the mesocolon A posterior gastroenterostomy is then performed Somervell remarks on the peculiar facts that the stomach can be deprived of enough of its blood-supply to put oxyntic cells out of action without interfering with its other functions, and that the cells so treated will fail to secrete acid for at least 2½ years The test-meal charts he publishes show a great and immediate reduction in acidity after this operation Thus in 10 cases before operation the total acidity of the fasting juice was 79, the average acidity throughout two hours was 70 and the maximum acidity during the two hours 94, three weeks after operation these figures had fallen to 52, 45 and 64, a year later they had fallen further to 29, 39 and 61 Ligature, in Somervell's experience, produces a more rapid fall in acidity than gastroenterostomy alone, though the late reduction is much the same, he is therefore more fortunate than most in reducing acidity with gastroenterostomy alone In 2 out of 3 cases in which ligature alone has been done a satisfactory fall in acidity was obtained He has so far ligatured the vessels in 150 cases, with no mortality, and is very satisfied with the results on top of un and won't let un git up, so the chap ketches 'old o' varther's arm in 'is teeth and bites a lump out's clean as a whip My varther takes 'old of 'is nawse and starts to twist un "Hif you bites me agin, you b——," 'e says, "I'll screw your bliddy nawse right orf, sure 'nough!" My brother thinks 'tis 'bout time vor to vetch the Sergeant and orf e goes arter un When they two comes back 'bout quarter'n hour later varther is still sitting atop this vur chap and 'im a man only 'arf 'is age, mind you Then, top of ivverything, varther goes and summonses un vor assault!

Great men have their biographers, great virtues a-recording, but today I mourn for one who was not known as great, yet seemed above all others to have the gift of friendliness When he first came to our camp he was a grubby little boy of ten—might he camp with us? Got a tent? No Got any grub? No-o He stayed six weeks, going from one troop to another, acting as guide in the woods and fields, showing town boys the skill of cooking the cockle, of spearing the dab and the flounder, of seeking the samphire One heard his shrill Doric all day, and like a cluster of sparrows he and his friends moved in a babble of noise, at night reluctantly desisting He came year after year and was greeted as one whom we had never really left In winter we would sometimes hear from him, hard fabricated letters, scented with the smell of hayfields and a summer's sea With foreign scouts his glowing friendliness made him at ease and soon he might have been of their own blood At the camp just before the war he was seventeen and working, but he came each evening helping in chores, and left soon after dawn He tried to join the Navy, but was found to be colour-blind, so went into the Merchant Service Here too his easy friendliness made him as one who had been known to each for all time On his second trip his ship was torpedoed homeward bound on a winter's night He was still alive when they dragged him into a boat, but died an hour later and was buried at Stornaway Throughout his few years he had nothing to offer but life and friendship, but he gave them both and they were gold His was a genius for aiding, the spirit sung by Kropotkin, which has done more for the advance of man then the skill of craftsmen, the wisdom of statesmen, or the beneficence of kings O Jimmy, may the reminding cries of the gulls and the sound of northern breakers and the love of many friends bear you peace

Today has in a small way been rather a red-letter day for me I have just given Sam his last pink certificate, for he has now reached the age of 65 Seven years ago he and I decided, rightly I think, that, owing to a combination of chronic bronchitis and osteo-arthritis, he had better give up the blacksmithing Every lunar month since I have called on him and stated, on the pink certificate provided for the purpose, that, in my opinion, he was not likely to be fit for work for a further period of 4 weeks I have made 182 ticks on his medical record card If my arithmetic is correct, I have written Sam's full name and disabilities and my signature 91 times each and the figure 4 182 times I am not prepared to work out the acreage of paper consumed, but it is nice to think that my laudable reiteration has at last carried conviction

"I'll bring my bitch along this afternoon, if I may," said my shooting companion, "she's useful though she may be a bit wild" She proved to be a young golden Labrador of great beauty but obviously very pregnant and not at all wild "She's a primigravida How far on would you guess she is?" asked my friend "Nearing full term I should imagine," said I, and the keeper hazarded the opinion that she wouldn't go much more'n a week. She hunted rather sedately and, walking homeward, we noticed a bag of membranes presenting She appeared to be in no distress but squalled at intervals whenever she had a good pain We spread a sack on the back seat of the car, made her comfortable and went into the keeper's cottage for tea Twenty minutes later we found she had had two pups, and a third was born as we drove home All are doing well

Public Health

Annual Reports

METROPOLITAN BOROUGHS

The population of the metropolitan boroughs has been shrinking for many years due in the main to emigration from the metropolis to the outer ring This migration, mostly of young married people with their families, explains the apparent increase in insanity, especially of senile dementia, with which the county council has to deal The borough which has suffered the severest depletion is *Shoreditch* which at the end of the last century had a population of 122,000 In 1938 the population was 80,000, but during the war this has shrunk to less than half In the past the borough was densely overcrowded both per acre and per hereditament Infantile mortality which was close on 200 in 1899 sank steadily to 31 in 1939, but rose to 69 in 1940 and 63 in 1941 Tuberculosis notifications sank from 6 3 per 1000 population in the last war period to 1 2 in 1939 and the tuberculosis mortality from 3 0 in 1903–07 to 0 7 in 1938 There has been a brisk rise in the past two years In 1941 notifications were 3 0 and mortality 2 2 per 1000 population, but in view of the disturbance of the population, this apparently alarming increase must not be taken too seriously

In *Islington*, new cases of pulmonary tuberculosis in 1941 were 40% and of other tuberculosis 23% above the 1938 figures, while the mortality increased 67% and 55% respectively Whilst there is no doubt that tuberculosis did increase in 1940 and still further in 1941, local returns must be read with caution One obvious factor augmenting the local rates is the rejection from the services of recruits found to be tuberculous on call-up These are returned to the civil population, so the tuberculosis-rate of young men in the civil population is very high indeed So far as can be told at present there has been a substantial decline in tuberculosis in 1942

In *Hammersmith*, increase in tuberculosis in 1941 was slight Dr J B Howell, in his report for that year, mentions that the old tuberculosis dispensary was destroyed and the work transferred to the British Postgraduate Medical School where "the work has been carried on under much better conditions, and in my opinion the Dispensary is now in the place where it always should have been, where the Tuberculosis Officer has the advantages of all the ancillary services" In Hammersmith the birth-rate in 1941 was 16 5, the highest since 1928, when it was 16 6

In *Hackney*, on the other hand, the birth-rate dropped from 15 2 in 1940 to 13 7 in 1941 At the cleansing station 248 children under five were treated for scabies, 1058 children over five and 1618 adults, 120 people, all adults, were also cleansed of body lice

THE OUTER RING

The townships of the outer ring show the other side of the picture They are not self-contained populations but in large part dormitories for the metropolis They vary greatly in the composition of their populations and still more in the powers possessed by their ruling authorities On the whole, they have excess of young married couples in rather favourable circumstances who work in London but can afford to live outside the capital and travel to their work Their health records should therefore be good and in general they are, though they show considerable variations Their birth-rates are much lower than they should be to maintain their populations by natural increase Taking four at random, the birth-rates in 1941 were 12 86, 11 65, 13 31 and 12 42 The corresponding death-rates were 13 95, 11 2, 13 46 and 12 65 Infantile mortality is also uneven, varying from 21 8 in Finchley to 63 in Hornsey Maternal mortality was low in most, but not in all In Wembley it was 4 30, in Hornsey 3 24, in Leyton it was 0

Dr A G Morison of *Wembley* (where 21 out of 95 infant deaths were certified as premature birth) says, with truth, that prematurity is now the greatest single factor in human mortality and the most promising line for the immediate reduction of infantile mortality is in adequate facilities for treating premature infants In Chicago and New Zealand much success has been

In England Now

A Running Commentary by Peripatetic Correspondents

I HAVE eighty cases of home-sickness here, old men evacuated from London They sit on the beach and hear the clutter of streets, they gaze out over the North Sea and dream of the Hackney Road Clearly the disease is pretty common in our animal world, it has anchored the ancient civilisations of the ants and bees, it is the motive of the migrant and the homer, and territoriality is its mainspring, it occurs more strongly in the young and the old or when there is need of protection as in illness and at nightfall, in the virile it alternates with wanderlust which is its manic form, it is the call to the beast from the earth that bore it In essence nostalgia, this return-pain, consists in a longing for home expressed in mental tastes, touches, smells, sounds and pictures, the whole composite animal thought-form

Even in man, who is degenerate in these respects, home-sickness retains a large element of taste, smell and touch, whose proportions vary at different ages The very young child longs for a person, his mother or his nurse, and the order of precedence here would probably be *touch, taste (including a feeling of repletion)*, smell, hearing, sight—the "lower animal" sequence At prep-school-going age, if the composite thought-form were put in words, the items in order of prominence might be something like this the house itself and its protecting personality, the birds' egg collection, the smell of the kitchen and the feeling after a good illicit meal, the feeling of being in bed and hearing the rain on the ivy, my rabbits, the feel of the lawn to bare feet, my mother and father, the hole in the shrubbery which I am going to make into a real cave and the smell and the gloom of it, John's ferret, the acorns I planted in the field, my sisters Later on the sisters may move up and be bracketed with the ferret, and the parents may take precedence over the rabbit Later on still it tends to be more diffuse—a longing for particular towns and counties Going on the long route round the Cape in the last war I used to walk up and down the deck with a London addict and sometimes he used to pretend we were walking from, say, Westminster Bridge to the Mansion House, and he discoursed on the streets and houses we were supposedly passing Then I would remember that when I used really to walk those same streets I was dreaming of Essex fields and elms It often beats logic, it will make a child return on the first day of a holiday she has been saving up for and talking about for months, and it packs people back to bad homes and bombed areas I once knew a Lewis Islander who got a very good job in the middle of Queensland, but he chucked it up as he was getting ill—he told me he could hear the sea breaking even in the Ford Some exiles may tell you they never get home-sick now, then suddenly comes a smell of bracken or of peculiar dust associated with some squeaky chair or room, and they have to answer quickly, for it is *home calling on the old nasal line* One never quite gets over it, thank Heaven, for although it can be devastating at times, on the whole it is a poignantly pleasant disease, moreover it is the strength of families and adhesive of nations There is only one cure—to go home—and it is a solacing thought, quite in keeping with the morbidness of the disease, that we shall all be cured at the great homecoming, when we return to dust

* * *

The credit for the following important discoveries in the rapidly growing field of homunculology should really go to George, my friend in the Army One day in the mess, after a particularly wearying sick parade, he was brooding tensely on philosophical questions, to the accompaniment of a steady flow of gin and limes (or gins and lime), when the light broke in on him "Of course!" he exclaimed, making the Padre choke over his beer "It's obvious, when you think of it! The Old Woman Who Lived in a Shoe wasn't a myth at all—she really lived, and all those children she didn't know what to do about are the ancestors of the Little Men Who Live in Army Boots! Why they should prefer Army boots is incomprehensible, but they do Every man I saw this morning was firm in his statement that he had never suffered from the machinations of these fellows when he wore civilian footwear, but that now is a martyr to them" George stopped for breath, in the pause the Colonel was heard to remark coldly though not a doctor himself he had always [illegible] excessive consumption of alcohol in the early part of the day unhealthy

The Major, whose cardiovascular homunculi had in the past few minutes screwed down the safety-valve and opened the throttle wide, now gave tongue in his usual bluff military manner "Rubbish! Nonsense! You doctors are far too soft-hearted! Little Men, indeed! *It's all lead-swinging, in my opinion* Why, out in India we used to march 50 miles a day, and no sick parades! Regulars, of course Grand fellows! But of course the Army wasn't permeated with all this new fangled Air Force stuff in those days They tell me the Air Force is full of these Little Men ideas—Gremlins, they call them—petrol-drinking Gremlins, sight-twisting Gremlins, Gremlins that breathe on the wind-screen and put dirt in the guns, and so on! But what can you expect in a Service with no traditions?"

The Major continued in this strain for some time, but George was too full of his discovery and other things to take much notice *H vesiculogenicus*, little men with stirrup pumps who pump water into the skin and make blisters *H pesplanogenicus* (George's latin, never very reliable, was giving way under the strain), the heavy little men who jump up and down on the arch until they knock it flat *H* —— (George's latin had now failed completely), the little men with hammers who live upside down under the inner sole, and industriously drive nails up through it The bootlace-gnawers and knot saboteurs are well known, but *it is not fully* realised, even in the high scientific circles such as George and I revolve in, that march fractures only occur in metatarsals previously weakened by the inroads of little men with pneumatic drills As George learnedly points out, any damage to the surface of a structure subjected to bending *leads to a local stress concentration*, with resultant failure under less then design loads He also suggests that bone may be liable to vibration fatigue, like metals, but this is above me, I prefer the more democratic homuncular theory.

* * *

"Salvage" is a word screamed at me just now from every newspaper and many hoardings, and paper, it appears, is still one of the main articles to be salvaged It is easy to grasp the difficulties of obtaining wood pulp and the hindrances to its ultimate distribution, so when I try to buy a book and am told that it is out of print owing to paper shortage, or when I am informed that my copy of the *Blanktown Guardian* can no longer be supplied owing to limitation of copies, I am disappointed but not vexed, and try to bear these discomforts with fortitude However, the information given in a reputable weekly that the circulation of Hedley Chase's books represents a greater supply of paper than a large publishing house used *in all its publications for six months* does not help me in this effort Then in a bookshop I visited a few weeks ago there was an enormous display of copies of the most recent effort of a medical colleague now resident in California It seems that so many copies were printed, presumably on the author's reputation, and so few are being sold that there has to be a special drive to get rid of the surplus It is a pity that the applications of Salvage should be so anomalous

* * *

My varther, 'e's a man sem'ty six year old and 'e can take a team o' 'osses and do a day's ploughin' so well's inny-body now *Wan thin 'e can't bide* is to yur a man swearin' at a wumman, and you knaws, darter, as us got some *drudful* neighbours T'other day the man opposight comes 'ome to 'is dinner and starts orf swearin' and blindin' to 'is missis Hup gits my varther, goes across to un and cracks un wan on the jaw Then this yur chap—a man ony thirty-five year old, mind—pushes varther back agin the wall and starts for to pitch into un purty smart Varther, 'e puts 'is 'and back agin the drang-pipe so's to git a gude shove orf like and springs vorrard, takin' the chap roun' the neck and back and turns un over on 'is arse like wink Down goes varther rhaphy with a Curtis No 1 abdominal belt not a truss. It is worn for three to six months The rationale [illegible] to prevent the "pot-belly" sag of the lower abdomen which often occurs after operation, associated with an dragging discomfort and sometimes a "bearing-down" [illegible]. With the stretching of the lower abdomen comes [illegible] corresponding expansion of the internal and external [illegible] The belt prevents this It may not be possible fit soldiers with belts, probably the exercises described [illegible] Brigadier Edwards to restore the tone of the lower abdominal muscles—in other words, abdominal rehabilitation—will achieve it more effectively, but I should be reluctant to start it before three weeks

Harley Street, W 1 HAROLD DODD

PROTECTION AGAINST BEE-STINGS

SIR,—In an article on bee venom in 1933 (*Lancet*, ii, 446) I called attention to the fact that about 2% of all people are seriously upset by bee-stings, and in a much smaller percentage death occurs The only remedy after the sting is adrenaline hypodermically if in time, and since the average time between sting and death is about 12 minutes this time is short It is therefore necessary to find a preventive I had recently been attending a woman with massive urticaria—a common manifestation of bee-venom poisoning—and found calcium so effective and speedy in action that I decided to try it in prospective bee-keepers For three weeks before attempting to handle bees the person takes one 'Ostocalcium' tablet (Glaxo) 3 times a day, and thereafter one tablet a day until the bees have gone to bed for the winter It is well on the first occasion for handling bees to have a doctor present with syringe and adrenaline, and deliberately to incite a bee to sting So far I have seen no general reaction from the venom in 8 keepers so protected, but time will show whether this is more than chance

Nottingham FRANCIS THOMPSON

Obituary

IVOR LLOYD TUCKETT

M D CAMB

Ivor Lloyd Tuckett, who died in the Isle of Wight from enteric fever on Nov 28, came of Quaker stock, his father from Frenchay, his mother from Falmouth *nee* Fox Born in London in 1873, he was educated at Marlborough and at Trinity College, Cambridge, where he took a double first and headed the list in the natural sciences tripos On completing his clinical training at University College Hospital, London, he qualified in 1898, and in the examination for the MB Camb. he was 300 marks ahead of the next candidate and was congratulated by Rose Bradford, who said it was an honour to examine him. After serving as house-physician at UCH he returned to Cambridge, where he had been made a fellow of Trinity at the age of 21, a record at that time As an undergraduate he had worked at physiological laboratories in Germany, and he now settled down to several fruitful years of research on the functions of the pancreas in relation to diabetes, and the degeneration of nerve-fibres This brilliant pioneer work, published in the *Journal of Physiology*, led to his appointment as assistant Downing professor of physiology, but a promising career was interrupted in 1906 by a breakdown in health Forced to abandon research Tuckett spent the next three or four years travelling, mostly in New Zealand. On his return to England he retired to Hertfordshire and occupied himself with country pursuits, taking several prizes as a rose-grower Soon after the outbreak of the last war he became anxious to use his medical knowledge, and at the suggestion of his friend Percy Flemming he offered his services to Moorfields, which owing to the call up of younger men was in need of help, and after gaining experience he acted as house-surgeon there during the war years On leaving Moorfields he served for a time as house-surgeon at the Norfolk and Norwich hospital, and in 1923 he settled in the Isle of Wight where he lived until his death, carrying on an ophthalmic practice at Cowes and Newport In later years he was elected a fellow of University College

Ivor Tuckett was a man of wide interests, an omnivorous reader with sound critical faculty, an expert debater and keen conversationalist His boyish zest for life, sprightly sense of humour and unusual physical activity remained with him until his last illness Nature in all her aspects and the mysteries of the human mind were of absorbing interest to him, and he made an intensive study of psychology and was himself psychoanalysed His favourite hobby was yacht racing and of late years he kept a small yacht in the Solent Tuckett's passionate love of truth and hatred of shams and superstitions led him to examine the claims of spiritualists and mediums, the outcome of which was *The Evidence for the Supernatural* (1911) which has since been issued in a popular edition He became a member of the Rationalist Press Association, for whom he delivered the Moncure Conway lecture in 1920 on *Mysticism and the Way Out* He was always thinking of others and helping those in difficulties, financial or otherwise, and his friends will remember thoughtful acts of kindness without number.

He married Miss Anna Wikman, of Lund in Sweden and they had one son Major Cedric Tuckett FRCS, RAMC

GLADYS JULIA CUTHBERTSON RUSSELL

M B ST AND, D P H

Dr Gladys Russell, who died on Dec 7, was an able doctor, a wise administrator, whose service to maternity and child welfare was single-eyed and disinterested She was born in St Cyrus, a village on the East coast of Angus where her father was schoolmaster, and educated at Montrose Academy and at St Andrews University where she graduated in 1919 After holding house-appointments at Dundee Royal Infirmary she became resident medical officer at the Lonsdale Hospital, Barrow-in-Furness, and later at the Children's Hospital, Pendlebury, where her interest in children was awakened She therefore took the DPH at Manchester in 1924, and joined the staff of the Cheshire county council as assistant medical officer for maternity and child welfare Two and a half years later she moved to a similar post in Monmouthshire and in 1928 she went to Leeds where her promotion was rapid Soon after her appointment the post of senior medical officer in the maternity and child welfare department fell vacant and she was chosen to fill it

During her tenure of office there have been great changes The department has expanded in many directions and with each expansion her responsibilities were increased Among the greatest and most important of these developments were the proposals which formed the basis of the reorganisation of the midwifery service after the passing of the Midwives Act 1936 which were largely the product of her brain and they have stood the test of practical experience

Dr Russell was the first woman to hold the office of president in the Yorkshire branch of the Society of MOHs and she was also a prominent member of the Medical Women's Federation, while her interest in the education and training of health visitors made her a valuable member of the examining board of the Royal Sanitary Institute

JOHN PERCIVAL BROWN

M B MANC

Dr J P Brown, who died on Nov 30, was born at Bacup in 1878, and he and his father, the late Dr John Brown, between them held the position of medical officer of health of that town for fifty-four years John Percival was educated at Manchester Grammar School, and Victoria University, Manchester, where he qualified in 1900 After holding resident appointments in Manchester and Macclesfield, he joined his father in general practice, and the rest of his life was spent in the service of Bacup until owing to failing health he retired a year ago Dr Brown was a corps surgeon in the St John Ambulance Brigade, and in 1926 he was appointed an officer of the Order of St John. During the last war he did valuable Red Cross work Keenly interested in historical medicine and legal medicine, he rarely missed a meeting of the Manchester Medico-Legal Society He leaves his wife with two daughters and a son, Surgeon Lieutenant Douglas Brown, RN achieved by treating immature infants as cases of deficiency disease, whilst at the same time research is progressing into the cause of prematurity

Dr Caryl Thomas of *Harrow* calls attention to the rise of paratyphoid which during the war has been spread mainly by artificial cream, though many stray cases occur in which the source of infection cannot be traced The fatality of paratyphoid in the past three years has been extraordinarily low, largely due to better recognition of mild and abortive cases, but possibly also to the medium by which most cases are infected

In *Leyton* in 1892 the birth-rate was 35 and infantile mortality 141 In 1941 the birth-rate was 13 31 and the infantile mortality 38 3 The highest infantile mortality in the half century was 155 in 1899, the year in which this rate soared to a high record in all parts of Britain 1911 was the last year in which the rate in Leyton exceeded 100 (116 6) and 1926 the last in which it exceeded 60 (64 8)

In *Hendon* measles and whooping-cough were prevalent in 1941, the former causing 3 and the latter 6 deaths Notifiable pneumonia was also exceptionally prevalent

Infectious Disease in England and Wales

WEEK ENDED DEC 12

Notifications —The following cases of infectious disease were notified during the week smallpox, 1 (at Swinton, Yorks), scarlet fever, 2769, whooping-cough, 1326, diphtheria, 1079, paratyphoid, 7, typhoid, 10, measles (excluding rubella) 13,287, pneumonia (primary or influenzal), 989, puerperal pyrexia, 174, cerebrospinal fever, 75, poliomyelitis, 7, polio-encephalitis, 0, encephalitis lethargica, 3, dysentery, 133, ophthalmia neonatorum, 69 No case of cholera, plague or typhus fever was notified during the week

The number of civilian and service sick in the Infectious Hospitals of the London County Council on Dec 2 was 1990, including scarlet fever 677, diphtheria, 258, measles, 304, whooping cough, 165, enteritis, 94, chicken pox, 75, erysipelas 37, mumps, 46 poliomyelitis, 2, dysentery, 14, cerebrospinal fever, 6 puerperal sepsis, 24, enteric fevers, 9, german measles, 1, encephalitis, 1

Deaths —In 126 great towns there were no deaths from scarlet fever, 2 (1) from enteric fevers, 14 (1) from measles, 5 (0) from whooping-cough, 21 (3) from diphtheria, 51 (5) from diarrhœa and enteritis under two years, and 42 (2) from influenza The figures in parentheses are those for London itself

The second fatal case of enteric fever was at Tynemouth Liverpool and Rhondda each reported 5 deaths from influenza, no other great town more than 3

The number of stillbirths notified during the week was 230 (corresponding to a rate of 38 per thousand total births), including 25 in London

FIFTH SUPPLEMENT TO THE BPC

THE latest supplement to the BPC 1934 (London Pharmaceutical Press, pp 38, 2*s* 6*d*) contains a full cumulative index to the changes made in this and the four previous supplements In part I monographs are added for prepared derris, with a new preparation, applicatio derridis BPC, and for lonchocarpus, both for the treatment of scabies The other changes in the monographs and formulæ are in preparations of which quinine is not regarded as an essential constituent Thus quinine is omitted from the formula and title of extractum malti liquidum cum quinina et strychnina, pilulæ ferri phosphatis cum quinina et strychnina, syrupus ferri bromidi cum quinina and cum quinina et strychnina, tabellæ ferri phosphatis cum quinina et strychnina Quinine also disappears from glycerinum hypophosphitum compositum, pilulæ ferri valerianatis compositæ, pilulæ podophyllini et quininæ, syrupus hypophosphitum compositus, syrupus triplex, tabellæ hypophosphitum compositæ, tabellæ phosphatum et hypophosphitum compositæ, and tinctura antiperiodica It will be news to many prescribers that all these preparations contained quinine In part II the only changes are verbal ones to allow synthetic rubber to be used in making surgical sheetings and plasters

---

The fact that goods made of raw materials in short supply owing to war conditions are advertised in this paper should not be taken as an indication that they are necessarily available for export

Letters to the Editor

CEREBROSPINAL FEVER, 1914-17

SIR,—A statement by the Minister of Health on p 688 of the *Lancet* of Dec 5, that in the c of cerebrospinal fever of 1914–17 two out of three were fatal, needs qualification The figures are p 147 of vol I, Medical Services, *Official History of Great War* They were as follows Troops in United Kingdom cases 3549, deaths 1640, 46 2% Civilian population cases 5306, deaths fatality 65 4% Total cases 8855, deaths 51 fatality 57 7% The Minister's remarks therefore to the civilian population only, since the fatality am the troops, far from being two out of three, was less one in two

East Molesey MERVYN GORDON

YOUTH PROBLEMS AND MENTAL HEALTH

SIR,—Dr Mayer-Gross raises matters of vital importance to the community Referring to wanton destruction of property by youths, and irresponsible behaviour and spread of venereal disease by girls, he states that psychopathic, and morally and mentally defective, persons are largely responsible for these acts He also suggests that such persons could be treated and the offences prevented if an adequate mental health service existed

Fully staffed and well-equipped psychiatric and child-guidance clinics can assess the mental state of an offender, but relatively few of these cases are amenable to psychiatric treatment in an outpatient department In many areas there is a lack of diagnostic facilities, but a more serious omission is the lack of suitable residential care and treatment to meet the needs of the individual case when the diagnosis has been made and the necessary measures decided on The overlapping of the functions of the Board of Education, the Ministry of Health, the Home Office, the local authority and the voluntary organisation adds to the difficulty and reveals the urgent necessity for a Ministry of Childhood and Youth A further aggravation of the problem already existing among the juvenile population is arising from the discharge from the Forces of men and women who, by reason of mental defect and psychopathic disability, are found to be unamenable to psychiatric treatment and unfit to serve

Liverpool MURIEL BARTON HALL

INGUINAL HERNIA

SIR,—In reply to Brigadier Harold Edwards's interesting letter, my adoption of the Bassini operation has been gradual during the past eight years, performed at first reluctantly because it required a longer effort and greater attention to detail than the operation for hernia ordinarily practised in this country The average English textbook does not detail Bassini's operation His description, now 50 years ago, still compels my admiration I have never seen a recurrent hernia after it, and this after a faithful follow-up which includes patients who have recurred once, twice, and in one instance three times previously There are certain operations which I have found difficulty in accepting, but which experience has proved to meet patients' needs They include subtotal thyroidectomy for the toxic thyroid, subtotal gastrectomy for a peptic ulcer, the muscle-cutting incision for exposure of the kidney, and the precise operation of Bassini for the cure of inguinal hernia, which admittedly distorts the anatomy a little, but in my hands has consistently cured

I fully agree that the time in bed after operation is important In my practice it is 16 days for the fit young adult with the indirect hernia, 18 days for double indirect and for unilateral direct hernia, and 3 weeks for the double direct hernia Recent work on the time required for union of tendons confirms that these periods are right and in no way too long I believe that some recurrences can be explained by the resumption of too early function

Another point which may be important in the avoidance of recurrence is fitting every patient after ts'—Miss F Horsbrugh Deliveries of the which the Minister referred in his statement on not yet begun In the meantime progress has the detailed arrangements for its use as soon to hand, and the Minister hopes to issue in the a circular to local authorities regarding the of the tuberculosis service in all its aspects rs of the allocation of the miniature radio- Arrangements have been made to make available for tuberculosis and as regards the for this and other forms of work, the Minister National Service and the Minister of Health detailed plans with the organisations concerned tive arrangements for the financial assistance Minister referred in his statement and on which with interested organisations are nearly he hopes it will be possible to give the necessary local authorities in the near future

Equipment for Lifeboats

to a question the Parliamentary Secretary to the described the equipment which the Ministry rt requires shipowners to provide in lifeboats a minimum supply of approximately 3 quarts of person. This is about treble the prewar require- more must be provided as far as is practicable is afforded by canvas hoods and weather fitted in the boats and by protective suits which are to all members of the crews An approved first aid renewed with expert medical advice, must also be also one gallon of fish, animal or vegetable oil ved substance for massage The emergency person are as follows

of fresh water	14 oz. biscuits
late	14 oz. milk tablets
mican (or other approved meat extract)	

ARD'S HOSPITAL FUND FOR LONDON

g of the fund on Dec 15, the Duke of Gloucester, dent, announced that this year £28,000 is to be to hospitals This is rather less than in recent the distribution committee have taken into account bility that there will be heavy demands on the fund e war They have also set aside £5000 for grants to ls for the establishment of preliminary training schools irses The committee hope that these grants will ge the smaller hospitals to set up schools, perhaps as terprises

Minister of Health in moving a vote of thanks to the said that the moment was notable, for the Beveridge had made a provocative contribution to the recon- theme One feature of particular interest both to to the fund was its assumption that comprehensive rehabilitation services will ensure medical treat- everyone This, as he had announced in the House r, 1941, was indeed the Government's intention and part of the Government's policy to maintain the that patients should make a reasonable payment the cost of treatment "The Beveridge report," Mr tinued, "recognises that the question of patients' ions and of contributory schemes is one which can only in relation to the whole problem of the n of hospital services, and one which will depend ral policy found best for providing those services s too early yet for me to determine the shape of that am now conducting all the preliminary spade work later be consulting the interests most concerned) n be more alive than I to the value of the practical in the past, and being done now, by the various ry schemes and also to their potentialities for the rticularly if they are able to converge a little more re uniform paths, for example in their rates of to hospitals and in their readiness to extend those equally to any hospital, wherever situated, to medical needs of a patient make it desirable to send ou have, I know, been putting a good deal of useful the questions of contributory schemes in London better correlation of their activities You would, I well advised to go ahead with this—perhaps particu the two aspects which I have just instanced—and s will certainly be of interest to us, in considering which it may be found best to expect these schemes n any long term hospital policy"

A CONTRIBUTION TO THE MYTHOLOGY OF CANCER RESEARCH

E L Kennaway, MD, FRS

Thomas Henry Huxley, in a well-known essay, gave a destructive estimate of *The Value of Witness to the Miraculous* (why can no-one write now as he did, either in spirit or in style?) But scientific workers often have reason to doubt the value of witness to the non-miraculous also

ARSENIC CANCER IN HORSES

The literature of cancer research contains frequent references to an alleged piece of evidence for the carcinogenic action of arsenic recorded by Dr J A Paris, MD, FRS, late senior physician to the Westminster Hospital, in his book bearing the title, lengthy as was usual in those days, of

> PHARMACOLOGIA, comprehending the Art of Prescribing upon Fixed and Scientific Principles together with the History of Medicinal Substances

which reached its 3rd edition in 1820 and its 5th edition in 1822 Dr Paris says "The poisonous effects of arsenious acid are so amply detailed in medical works, that it would be superfluous to dwell upon them in this place, it may however be interesting and useful to record an account of the pernicious influence of arsenical fumes upon organized beings, as I have been enabled to ascertain in the copper smelting works of Cornwall and Wales This influence is very apparent in the condition both of the animals and vegetables in the vicinity, horses and cows commonly lose their hoofs, and the latter are often to be seen in the neighbouring pastures crawling on their knees and not unfrequently suffering from a cancerous affection in their rumps, whilst the milch cows, in addition to these miseries, are soon deprived of their milk, the men employed in the works are more healthy than we could *a priori* have supposed possible, the antidote upon which they all rely with confidence, whenever they are infested with more than an ordinary portion of arsenical vapour, is *sweet* oil, and an annual sum is allowed by the proprietors in order that it may be constantly supplied, this opinion is not solitary, for Tachenius relates that the poisonous effects, such as convulsions, gripes, and bloody stools, with which he was seized from exposure to the fumes of arsenic, were relieved by milk and oil"

Dr. Paris does not say how he obtained this information, but the *Dictionary of National Biography* tells us that he practised medicine in Penzance from 1813 to 1817, so he had opportunity to collect such data in Cornwall However, the statement quoted was obviously of little or no value as evidence even at the time of publication, for several reasons (1) There is nothing to show the cancerous nature of the alleged tumours; one does not of course blame Dr Paris for this, for the microscopic diagnosis of malignancy had not then been begun (2) We are told nothing about the incidence upon the cow-population-at-risk (3) Dr Paris does not tell us, as a modern investigator would be expected to do, whether the curious incidence of these affections upon hoofs and rumps was the same in Cornwall, and in Wales, moreover, in his fifth edition, published only two years later, he omits all reference to Wales without any comment on this change (4) No attempt is made to show that arsenic, among the various emanations from the industry, was the active substance And surely, if no better evidence than this has come from the locality in question during more than a century, the writers on cancer who have quoted and requoted it over and over again during this period should have come to regard it as still more suspect

Dr Paris goes on to say "It deserves notice that the smelters are occasionally affected with a cancerous disease in the scrotum, similar to that which infests chimney-sweepers, and it is singular that Stahl in describing the putrescent tendency in the bodies of those who die from this poison, mentions in particular the gangrenous appearance of these parts"

Seventy years after the appearance of the 5th edition of Dr Paris's book, Henry Butlin, surgeon to St Bartholomew' ospital, who had a very different standard of ac [illegible] igated this matter To Butlin, no

Parliament

Compulsory Treatment of VD

ON Dec 15 Dr **EDITH SUMMERSKILL** carried with her into the "ayes" lobby 30 other members, including Dr Morgan, in support of her prayer for the annulment of regulation 33B The "noes" numbered 245 and included 9 medical members Dr Summerskill said the Minister of Health was toying with the problem and delaying real action Last year there were 70,000 admitted new cases of venereal disease, and probably as many more untreated or untraced We had gone back to the situation of 1932 and would soon be back at 1928 when 16,000 expectant mothers were found to be infected Let us have more clinics, and for women clinics where all their complaints are treated, let us follow up contacts, but if a patient ceases attendance let an order be served on him She quoted Major S M Laird as having said that as a result of compulsory notification in Sweden the defaulter rate in 1935 was only 2 5%, while in this country (without compulsory notification) it was 82 5% But Mr Brown later called the comparison fallacious because the English figure was obtained just by subtracting from 100 the percentage of cases stated to have completed their cure in that year The regulation as framed might, she said, cause hardship and injustice to some unfortunate woman, but it would be ineffective and she called on the house to be bold, frank and courageous —Mrs **HARDIE**, in seconding the motion, agreed that the regulation would be useless and dangerous All she wanted was an extension of confidential medical treatment, combined with a great educational effort

Sir **FRANCIS FREMANTLE** thought we were all agreed that venereal disease should be treated like other diseases and equally agreed about moral and educational measures, had these been under discussion But he blamed the house for being unwilling to look disgusting facts in the face and failing to sense an immediate peril He recounted the change of medical and scientific opinion from regulation of prostitution to the provision of free and secret treatment , he recalled the rejection of the Edinburgh Corporation Bill 1928 for fear it would impair the voluntary system But what, he said, is the good of pretending to set up clinics when you have not the doctors to man them ? Notification without treatment is a waste of time and this regulation brought in, like other public health measures, in a small way should be tried out to see how far it is efficient —Dr **HADEN GUEST** warmly endorsed this view and spoke of the definite problem of saving men and women, in the Services and shortly to be called up, living in conditions favourable to a grave spread of venereal disease The press had done admirable work in publicity during recent months, leading up to the frank and free broadcast discussion But what was the value of notification, or even treatment, if not directed to the source of infection ? To set up in this country clinics on the Swedish standard would mean multiplying them by ten or more Nor had compulsory notification prevented the rise of venereal disease in the Services —Sir **ERNEST GRAHAM-LITTLE** said that science should regard the present situation as an epidemic which could not be stopped by ordinary safeguards He was not himself fond of notification he thought it destroyed to a large extent the privacy which ought to attend medical treatment The Minister might later find it necessary to extend his powers to include notification , meanwhile, let us take this regulation as an instalment —Capt **G S ELLISTON** agreed with Mr Graham White that no government dare resist the responsibility of enforcing some regulation of this kind , we could do no other than apply public health measures to secure treatment for the small group of cases which played a big part in spreading infection —Dr **H B MORGAN** opposed compulsion in any form whether in notification or treatment "I have never yet known a case," he said, "when the situation was properly explained in strict confidence, that would not accept treatment" If the Minister did not know how to work the voluntary method, let him ask psychologists

THE MINISTER'S REPLY

Mr **ERNEST BROWN** registered agreement that venereal diseases are an evil which must be stamped out if possible, that their spread hampers the war effort, that moral and ethical issues lie behind the que Promiscuity could not be made safe and the MRC refused the task of recommending a prophylactic ought to do our utmost to extend and improve spread of accurate knowledge and steps had been t to coordinate education in this subject with all health subjects by the Central Council for Education The press had been most helpful and a constructive and sane discussion on a healthy should help the religious forces in this country to their own case clear Is special action needed The debate made it clear that there was opinion for such action , perhaps the dissentient outside was larger in bulk than in the house minister would raise the issue unless there were cause for doing so In prewar days the voluntary was not failing, although more might have been His aim was to strengthen that effort, not to Regulation 33B was only part of the answer problem The three main essentials were public tion, adequate free treatment and indirect action courage promiscuity But he claimed for the reg that it represented a new approach to the prob public health approach It did not attempt, as did of the last war, to control solicitation and it discriminate between the sexes Medical officers always done their best to find out where the disea contracted (To use the word "informer" for described as somewhat far fetched by 7 medical in charge of VD clinics in a letter to the *Daily T* Dec 15) It was their public duty Regulation gave the doctor the power, or rather the duty, to information on, but not to anybody in public notification is made every attempt will also be get the person to come voluntarily The the regulation had already caused some who had volunteered for treatment to come forward

Dr **RUSSELL THOMAS** what remedy there was innocent party against whom information had been Mr **BROWN** replied My hon friend has got it pletely wrong All that they are asked to do is to for examination in complete secrecy There is no discussion If the MOH on the local authority reason to believe there has been malice, very penalties are provided

QUESTION TIME

Edinburgh Smallpox Outbreak

Mr **A EDWARDS** asked the Secretary of State for Sc whether he would give the dates of the development smallpox rash or chickenpox rash in any cases believed to be chickenpox, in the cases diagnosed as during the recent outbreak at Edinburgh , and the their removal to hospital ?—Mr **T JOHNSTON** replied only smallpox case in the Edinburgh outbreak which originally diagnosed as chickenpox was the first case covered in the Royal Infirmary The rash appeared Oct 27, and the patient was removed to the City Fever pital next day —Mr **EDWARDS** How many of the four fatal cases of smallpox in Edinburgh and district had been patients in a medical institution or an associated convalescent home before they contracted smallpox ?—Mr **JOHNSTON** There have been six deaths from smallpox since the present outbreak started in Edinburgh The first four of these had been patients in a medical institution or associated convalescent home in Edinburgh on the probable date of infection The two other patients had no connexion with the institution or home —Mr **A EDWARDS** Was the first case of smallpox at Edinburgh taken to the Royal Infirmary suffering from some other illness and did the supposed chickenpox attack develop afterwards, or was the patient taken to the Royal Infirmary as a case of chickenpox ?—Mr **JOHNSTON** The first case of smallpox in Edinburgh was in the Royal Infirmary for another illness when an illness developed which was at first thought to be chickenpox As infectious disease is not treated in the Royal Infirmary, he was removed to the City Fever Hospital, where after examination he was diagnosed as a case of smallpox

Planning for TB Control

Mr **JAMES GRIFFITHS** asked the Minister of Health wha progress has been made in carrying out the steps to combat tuberculosis recently announced , and what arrangements have been made in regard to the provision of financial assist-

trouble was too great if he could learn anything about the cause of "chimney-sweeps' cancer", his laborious travels and inquiries are described in three lectures *On Cancer of the Scrotum in Chimney Sweeps and Others*, delivered before the Royal College of Surgeons of England in 1892, which are well worth reading or re-reading (*Brit med J* 1892, i, 1341, ii, 1, 66) Butlin went to Cornwall to see what he could learn of the phenomena described by Dr Paris, and in his third lecture gives the following account of his inquiries

> "This remark of Paris has been referred to or quoted by several authors, both English and foreign, but I have failed to find the smallest evidence on which it can rest As Dr Paris spoke especially of the smelting works and burning houses of Cornwall, I made careful inquiries of the doctors at Camborne and Hayle In the neighbourhood of Camborne there are several tin burning houses, the tall chimneys of which puff forth a white smoke The surrounding fields are very poor in vegetation and there are but few cattle in them The atmosphere is said to be unhealthy to animals and men, rather from sulphurous acid than from arsenic I was told that not long since an action had been brought by a gentleman in the neighbourhood to restrain the tin-burners from continuing to burn tin there The plaintiff declared that he had lost a horse owing to the unhealthy fumes, but he lost his action also Mr Pike, a gentleman largely engaged in the mines, told me that there is but little arsenic now compared with what there was a few years ago Neither Dr Hutchinson, who had been more than thirty years in practice in Camborne, nor my brother, who has been practising there for more than twenty years, nor Dr Erskine, with ten years' experience of the diseases of the people, ever remembered to have met with a case of cancer of the scrotum in the whole course of their experience
>
> Hearing that tin smelting is carried on at Hayle, I drove there, and called on Dr Mudge, who has been for very many years in practice, and, with his sons, attends a very large area around Hayle, and is familiar with the diseases of the work people of all descriptions He said that the smelting of tin is not now carried on to the same extent as formerly in that neighbourhood Dr Mudge remembered to have seen in past times eruptions and even rawness of the scrotum and insides of the thighs of the men exposed to the fumes of arsenic, but he had never seen a case of cancer of the scrotum, although he had seen several cases of cancer of the penis Speaking of the effect of the arsenical fumes on animal life he had never seen the loss of the hoofs of horses and cows described by Dr Paris On more than one occasion of late years the death of a cow had been attributed to the fumes of arsenic, and attempts had been made to obtain damages from the smelters The viscera of some of these animals had been sent to Dr Herepath, of Bristol, who had quite failed to discover arsenic in them He further told me that the skin affections of the scrotum were healed by very simple measures when the en washed themselves, which they very often neglected to o when they were in good health"

These statements by Paris have been quoted over and over again by writers on cancer, but I do not remember ever to have seen in this literature any reference to Butlin's criticism

The character of the information contained in Dr Paris's book, which is still offered to cancer research workers as authoritative, may be illustrated by a few items taken at random from the index

Acetification of milk by a thunder storm bears some analogy to the operation of depraved digestion	102
Ale, the supposed lithonthryptic properties of	212
Enemata, Clysters, calculated to fulfil five great indications	315
Prescott, Miss, persons of the first respectability became the dupe of	20
Tea and turtle soup, whether their admixture in the stomach may not form leather	314
Turner, Mr, why he escaped from the dose of arsenic administered to him in yeast dumplings	333

and so on

The writing of this note was suggested by the fact that the 120th anniversary of the publication of Dr Paris's 5th edition in 1822, and the 50th anniversary of Butlin's lectures in 1892, has just been marked by the inevitable reappearance, this time in a large monograph, *Occupational Tumors and Allied Diseases*, by W C Hueper (Springfield, Illinois, 1942), of the story of the cows' rumps, which is once again offered as serious evid of the carcinogenic action of arsenic The refe is given wrongly in the book in question as "P J A, Pharmacology, 3rd ed W. Philipps, Lon 1822", actually the title of the book is *Pharmacol* the year of issue of the 3rd edition is 1820, and publisher is W Phillips Hence the reader is offered inaccurate reference to a statement of little or no v in an obsolete book

After quoting once more the often-quoted pas about the cows' rumps and cancer of the scrotum, Hueper (*loc cit*, pp 36 and 41) makes the follo comments " . *Paris noticed the high incidence* cutaneous malignancy among the men employed these factories" This is a somewhat highly colou and extended version of Paris's simple statement "the smelters are occasionally affected with a cance disease in the scrotum " Dr Hueper proc " Paris mentioned the development of cance ulcers in domestic animals (horses and cows) grazing meadows situated close to the copper smelters and burning establishments The arsenical fumes rele *from these plants into the atmosphere were precipit* upon the vegetation of the adjacent countryside arsenic contaminating the grass of the meadows *ingested by grazing animals and thus caused the deve* ment of the cancerous lesions" This picturesque a tion about the grass of the meadows and the gra animals adds nothing whatever to the very question value of Dr Paris's story, it is not what Paris and he makes no claim that the arsenic was taken the mouth, it is surely quite possible that in such neighbourhood arsenic might act upon the skin direc from outside Lastly, Dr Hueper, like most of the writers who have quoted from Paris, lays down cancer occurred in horses, whereas Paris makes no statement We may now await the next appearanc the story in the literature of cancer, and may re upon the phenomenon described, I think by Wil Trotter, as "the mysterious viability of the false"

CARCINOMA OF THE NASAL MUCOUS MEMBRANE IN SH

Niebeile[1] describes the occurrence of carcinoma of *nasal mucous membrane occurring in a single h* inbred flock of Hampshire sheep on the Limbach es in Saxony Cases of this disease had appeared du several years and ten cases occurred during the cours a few months The author describes these tumour "carcinoma of the ethmoid bone which corresponde essential character to the normal histological struc of the olfactory mucous membrane," and he gives naked-eye figures of tumour masses in the nasal ca and a microphoto showing obvious carcinoma W regard to ætiology, the author makes the interes suggestion that the occurrence of this tumour in a si strain of sheep is comparable to the incidence of mamm cancer in certain strains of mice, but he considers also possibility that arsenic might be concerned, as follow

> "Zum anderen ist aber zu beachten, daβ das Ritte Limbach in der weiteren Umgebung der Freiberger Hu werke liegt und daβ Schäden durch arsenhaltigen Flugst unter den Rindern der dortigen Gegend *nicht* selten Allerdings handelt es sich bei diesen Arsenschäden, so ich sie bisher untersuchen konnte, stets um akute, Geschwürsbildung im Verdauungsapparat einhergeh Veranderungen"

which may be translated

> "One must take into consideration *also that the* Lim manor lies in the remoter neighbourhood of the Frei smelting works, and that lesions due to arsenical fume not uncommon among the horned cattle of that dist But these arsenical lesions, as far as I have hitherto been to investigate, *always consist in acute changes*, with ulc tion, in the digestive tract"

Estimations of arsenic in organs of sheep bearing na tumours, carried out in the Institut fur Gerichtlic Medizin in Leipzig, are reported "Portions of t brain were first examined These have extrem minimal amounts of arsenic, and contain actually *l than* 0 1 mg/kg brain substance" In the tumo "only extremely minute amounts again *less th*

---

[1] Niebeile, K / *Krebsforsch* 1939-40 49, 137

> /kg could be detected " In liver " an amount of /kg was found, that is, relatively considerably in the brain and tumour "

his clear and concise account of the available eberle draws the following cautious conclusion the pathogenesis of the endemic ethmoid cancer k of sheep on the Limbach estate is obviously explained However, I think that a certain of the disease with the locality and with by arsenic can scarcely be excluded " In 's textbook (p 41, see also p 408), Nieberle's n, and very guarded conclusions, undergo the transformation

> th, Nieberle reported the endemic occurrence of oma of the nasal sinuses in a flock of sheep kept fume and dust zone of these smelters in Freiberg He that this condition was caused by the chronic ion of arsenic, as not only was arsenic found in the tumour tissue and liver of the affected animals, but of acute arsenic poisoning with gastrointestinal tions were not uncommon among the sheep which the cancerous animals "

version of Nieberle's paper is either wholly mis-, or false, in every single particular (1) His non-phrase " in the remoter neighbourhood of the smelting works," appears as " sheep kept in the d dust zone of these smelters in Freiberg " [2] rle's inability to exclude arsenic becomes a direct on that arsenic is the cause of the tumours emphasis laid by the medicolegal analyst upon uteness of the amounts of arsenic in the brain ours is ignored (4) The last statement is simply There is no *mention whatever in the paper of any* ks of acute arsenic poisoning with gastro-intestinal tations ' in " the sheep which furnished the us animals " at Limbach , these attacks occurred horned cattle in the vicinity of Freiberg (' unter dern der dortigen Gegend " , see passage quoted above) The whole import of Nieberle's statement contrast the acute intestinal lesions due to arsenic the horned cattle around Freiberg with the slow tic changes in the sheep at Limbach and this t is simply ignored, and the whole sense of the reversed, in the quotation given above from the k

ARSENIC CANCER IN DEER

[3] investigated a disease affecting the wild mam- (red deer, roe deer, hares, foxes) of the Tharandter lying to the east of the mines of Halsbrucke and nhütten in Saxony, and characterised by loss of blackening of the skin, thickening of the stratum and extreme emaciation As many as 60–70% red deer were affected " Often horny warts were d abundantly over the skin, or it was covered horny desquamation (Manchmal war die Haut 1 mit Hornwarzen besetzt oder mit Hornabschil- uberzogen) " The context indicates that these were found in red deer, though the species is not explicitly , the skin of the roe deer was in almost way less affected These warts are the sole ic structures recorded by Prell in his report of the tion of 41 red deer, 102 roe deer and 27 hares paper of 14 pages cancer is mentioned once only l) in a sentence which refers to our general know- of the action of arsenic Several hundred estima- of arsenic in the organs of these animals were made ranged from a few mmg /kg to 42 mg /kg in the and to 12 mg /kg in the hair " (Cf analyses on h sheep above) Arsenic was often absent in the of animals showing the lesions described above, never present in those not showing such lesions is a zoologist and makes no claim to knowledge ology A part of the pathological work was undertaken by Professor Hofmann of the Hygienisches Institut der Technischen Hochschule in Dresden, who contributes a short paper, *Die Gefahrdung der Tierwelt durch Industriegase* (to which curiously enough Hueper makes no reference either in the text or in the bibliography) following immediately that of Prell (*loc cit* , p 670) Hofmann devotes five words to the single cancer, in a roe deer, which was discovered in the whole course of this investigation—" Weiterhin sahen wir aktinomykotische Auflagerungen auf der Pleura eines Hasen und ein Hautcarcinom bei einem Reh " Hueper gives the following account of Prell's results

> " Prell reported in 1936 the occurrence of extensive arsenical injuries among the domestic and wild animal life in the region of Freiberg, Saxony, where numerous smelters (silver and lead) released arsenic containing fumes into the air It was shown that these arsenical fumes were spread over an area measuring 50 km in diameter and settled upon the vegetation Horses, cows, goats, and pigs, feeding on this vegetable matter, developed loss of hair and hyperkeratoses, while melanotic spots and precancerous warts were seen occasionally on the skin of deer inhabiting the forests of this region A carcinomatous lesion was found in one deer In addition to the cutaneous manifestations of chronic arsenic poisoning domestic, *as well as wild animals* were affected by arsenica enteritis, gastric ulcers and cirrhosis of the liver There existed in this area an extraordinary mortality among insects, especially bees "

When one compares Hueper's version with the original, one finds that Prell makes no mention whatever of any hyperkeratoses in horses, cows, goats or pigs, nor of any " extraordinary mortality among insects " *other than bees, apart from a bare statement of a* mortality among silkworms Hueper chooses to describe the warts in deer as ' precancerous " Possibly they were precancerous, but Prell does not say so A transcriber has no right to colour the evidence of a first-hand observer by the insertion of such a word There is the less justification for this addition in that these " precancerous " warts occurred chiefly or solely in red deer, in which not a single cancer was found

[Anyone who reads the actual papers of Prell and Hofmann must surely be struck by one view of the matter which is the reverse of that advocated by Hueper Hofmann emphasises the importance of analyses of arsenic in the tissues because the evidence of morbid anatomy alone cannot prove that any given lesion is due to arsenic, and points out that it was by means of estimations of arsenic " that the so called Hüttenrauchkrankheit (smelting-fume disease) of horned cattle in the district of the Freiberg smelting works, which had been known for many decades was recognised as chronic poisoning by arsenic The clinical phenomena, such as chronic diarrhoea cough, scleroderma chronic squamous eczema muscular atrophy paralytic weakness, emaciation, &c , give no more proof of chronic arsenic poisoning in the cattle than do the post-mortem findings, which consist chiefly in the presence of old ulcers and scars in the abomasum and small intestine It was the demonstration of arsenic in the organs of the diseased cattle which brought the clear recognition that the so-called smelting-fume disease was a chronic arsenic poisoning " This extensive list of widespread pathological changes observed in numbers of cattle over a long period [4] contains no reference to the detached hoofs and cancerous rumps of the Paris tradition nor to cancer of the nasal mucous membrane such as occurs in the Limbach sheep (see above), nor indeed to cancer in any form This absence of malignant growths in cattle, and the yield of one single cancer from the examination of 143 deer and 27 hares exposed to arsenic, surely amounts to evidence against rather than for, the carcinogenic action of arsenic in these animals, of whom presumably a few at any rate live long enough for the development of malignant growth]

SUMMARY

Elsewhere [5] Hueper summarises the matter thus " arsenic cancer has a relatively long latent period,

---

has no means *of* knowing the exact distance of the estate e the sheep are kept from the smelting works Stieler's *d Atlas* shows unfortunately two places called Limbach one km and one 19 km from Freiberg and respectively 45 and 4 km from Halsbrücke one of the two sites of the smelting named by Prell The other Muldenhütten does not r on the map Prell (*loc cit* p 669) says " The effective of suspended arsenic is much greater than is usually pposed (it extends under some circumstances to a distance of 20 km or more) '

, H *Arch Gewerbepath Gewerbehyg* 1936–37 7, 656

[4] Prell (*loc cit* p 667) says that a good description of the smelting-fume disease " was given in 1878 by Haubner Director of the Royal Veterinary School in Dresden

[5] *Cancer Res* 1942 2, 559 The references 5–7 are to Nieberle, Paris and Prell

usually surpassing that of the average life span of the species used in such experiments This contention is supported by the observation that animals with a much longer life span (horses, sheep, deer) have developed an environmental type of arsenic carcinoma of the skin or of the nasal mucous membranes (5–7) "

What is the evidence for this generalisation concerning "an environmental type of arsenic cancer" in horses, sheep and deer?

(1) *Horses* —Dr Paris does not claim any cancers in his hoofless horses, and even such slightly neoplastic structures as hyperkeratoses are not recorded in horses by Prell What evidence is there in the literature that cancer has ever been produced in horses by arsenic? (For some reason, Hueper omits altogether from his list cows, the species in which Paris claims cancerous growths)

(2) *Sheep* —There are no definite grounds for the argument that the nasal cancer of the Limbach sheep is due to arsenic

(3) *Deer* —This use of the plural is not justified by the single carcinoma of the skin found by Prell and Hofmann in 102 roe deer and 41 red deer This solitary tumour may possibly have been "an environmental type of arsenic carcinoma," but one must bear in mind that we have no data on the spontaneous occurrence of epithelioma in roe deer

This then is the basis of the important generalisation, that horses, sheep and deer have developed an environmental type of arsenic cancer It is desirable that such statements should be examined before they are finally built into the permanent fabric of textbook tradition, from which they cannot by any possibility be eradicated

A Factory Antenatal Service

At a meeting on Dec 11 of the maternity and child welf group of the Society of Medical Officers of Health, with Catherine Morris Jones, the president, in the chair, an exp ment by which an antenatal and gynæcological clinic w established within the precincts of a factory was described Dr L B Bourne, medical officer to the factory, and Mr J O'Sullivan, consultant to the works clinic The clinic, situated in premises outside the workshops and can be visi by women unknown to their fellow workers An appointme system prevents waste of time, and the medical staff are al by their knowledge of the woman's condition of health modify her working hours immediately when necessary O'Sullivan commented on the continued good health of m of the women, who carried on their work of making ra parts up to a late stage of pregnancy Fatigue he thoug could usually be ascribed to the strain of shopping and ho duties carried out in addition to the factory work, rather th to the work itself The speakers put forward their pione experiment as a war time measure only, but claimed that had already justified its existence by lessened absentee and improved team-work among the workers The cli was popular among the women

“ the question might be raised whether at the pres state of the practice of surgery a surgeon should any long concern himself with these questions of anæsthesia, or lea them in the hands of the anæsthesiologists My feeling that there are as yet too few of them, and that we still mu concern ourselves with the subject of anæsthesia becau I find that when a patient dies under an anæsthetic I am t person who has to tell the family ”—Dr F A Colle *Ann Surg* 1942, **116**, 564
